When the drawing is finished, it is laid in the etching-trough; nitric acid, diluted with water (say 1 part of acid to 100 parts of water), is several times poured over the stone. Dissolved gum-arabic is then spread over it. If the dissolved gum be mixed with the acid, the finest lines are not so suddenly attacked by the acid, and not so easily injured.

This process requires great care, and a rule for the proportion of the acid can scarcely be established, as it varies in strength and frequency of application, according to the style of drawing, hardness, and temperature of the stone, and quality of the chalk.

Engraving on stone.—A hard stone, gray or bluish, is etched first, with acid in the trough, and gummed (some do not etch, but merely gum the stone); when dry, the gum is washed off, and a mixture of powdered Paris black, with water and a very little gum, is spread over the stone, and smoothed down with a large flat camel-hair brush, or with the palm of the hand. Some prefer a red to a black ground. Where great precision is wanted, the black ground is preferable; but for free working of drawings, the red one is better. The red ground is applied by washing off the stone nearly the whole of the gum, after it has been etched, gummed, and dried. The small quantity of gum remaining on the stone is then allowed to dry, and powdered dry red, or red chalk, is rubbed on the stone with the palm of the hand. Black tracing-paper is required for the red ground, while on the black-grounded stone a red tracing-paper is required. The instruments for engraving on stone are fine and broad-pointed steel-gravers, fixed in holders of wood, and small points of diamonds properly fixed by the jeweller. The engraving is done, not like engraving on copper, but more in the manner of a careful drawing in pencil. It does not require to be cut very deeply. The drawing appears white on a dark ground. Any mistake may either be polished out with fine pumice-stone, or carefully taken out with the broad scraper; the spot is prepared afresh with acid, rubbed over with red chalk, and the engraving rectified. Smaller mistakes may be covered with a little weak phosphoric acid mixed with gum, and the lines so covered will not take on the printing-ink. When the drawing is finished, linseed oil is put over every line, and the whole is then cleaned away with water and a bit of coarse flannel. After the stone is thus freed from the ground and oil, a piece of coarse flannel, containing printing-ink, is rubbed over the whole stone, until every line appears distinctly in black, and then the stone is again gummed.

Engraving on stone is particularly suited for work where great minuteness and sharpness is essential. The maps of the survey of the Bavarian and other continental governments have been engraved on stone, as well as many of the beautiful maps of the survey of the Austrian staff, copies of the latter having been shown by the Austrian government at the Great Exhibition of 1851.

Etching on stone is similar to etching on copper. The stone, after it has been prepared with weak nitric acid, is, in the first instance, coated with gum, and allowed to dry. The gum is then washed off, but a little is retained on the stone. When again dry, the stone is warmed, and the etching ground is spread very thin over it. The working with the etching-point, and the etching with acid, are then done precisely as on copper. When the drawing is ready, clean water is poured repeatedly over the stone, which is afterwards washed in diluted acetic acid (wood vinegar), it is cleaned again with water, and allowed to dry thoroughly. After this, a roller with printing-ink is rolled over the dry stone until it is quite black. The whole is then removed with oil of turpentine and water, when the drawing appears in clean black lines, after which the stone is gummed. The printing is effected in the usual way with the printing-roller.

Litho-
graphy.

Many beautiful drawings have been, and are yet, produced in Germany in this way; but somehow the style has never been extensively employed, from the many failures which are apt to occur during the first trials.

Autography on plain paper; Writings and Drawings on prepared lithographic paper.—Many government and banking offices, on the Continent and in Britain, produce their own circulars in the following simple way, which is properly called autography:—With very little lithographic ink in the pen, write only on one side of the paper (any good writing-paper may be used). When the writing is finished, a stone is slightly warmed, the written paper is sponged on the back with diluted nitric acid, and laid for a moment between blotting-paper; then the sheet is placed with the written side upon the stone, and passed *once* through the press. The sheet now adhering to the stone, is washed over with water on the back, and when the paper becomes quite soft, it is removed, by rubbing repeatedly with the hand. Gum is then put upon the stone; the printer takes a linen or flannel rag, containing some printing-ink, sprinkles water on the stone, and carries this rag rapidly in all directions over the writing, which now assumes a darker colour. The stone is then gummed again, and put aside until quite cooled. Before printing, some printers remove the gum, and pass a roller, containing what is called preserving-ink, several times over the writing, after which the stone is etched slightly; this, however, is scarcely needed where only a small number of impressions is to be taken.

The beautiful lithographic writings, plans, and sketches, on a coated lithographic paper, which are produced in Britain, and especially in Scotland, have never been equalled in other countries. The paper which is used should be well sized. The composition with which it should be covered is made as follows:—1 part gelatine or isinglass, 1 part flake-white, and as much gamboge as is needed to give colour, are dissolved over a slow fire, then sifted through muslin, and spread once, *in a very warm state*, with a large flat camel-hair brush, on one side of the paper. Some repeat the process. When dry, it should be passed several times through the press, over a polished stone slightly warmed, or better, a steel-plate, so as to be thoroughly smooth. Transparent quills and lithographic steel-pens are used for the writing. Any mistake is erased with a pen-knife, and the place covered again with the composition, of which the writer should have always a small corked bottle beside him.

When the drawing or writing is ready, it is put between damped blotting-paper, a warmed stone (not hot) is adjusted in the press, and after a few minutes the sheet of paper is placed upon the stone, and five or six times passed through the press; then the back of the paper is sponged with water, and the stone turned in the press; and with this change to compensate for inequalities of pressure, it is passed again five or six times through the press. This process may be repeated several times; and when it is finished, the back of the sheet is covered with water, and rubbed with the fingers until the portions of the paper come off. When the paper is entirely removed, the stone is subjected to the processes already given under "Autography."

Transfers from old engravings.—In Paris, a number of years ago, Paul Dupont made very interesting attempts to reproduce, by transferring to stone and zinc, old impressions of prints, woodcuts, type-printing, &c. The method is very simple. The old impression is thrown into a large flat basin filled with water, and a small portion of acid; and after it has been thoroughly soaked with the water, a small soft sponge containing lavender or nut-oil is repeatedly passed over the lines of the engraving, to strengthen the fatty portions of the dried up ink of the lines. The drawing is then transferred in the way already explained under "Transfer of Autography." Total failures, however, often

take place with this process, and even if the transfer succeeds, more or less touching is needed; and it is only when the engraving is not too fine, and a few years old, that a satisfactory transfer can be obtained. M. Dupont and others have spent large sums of money without producing practical and satisfactory results. Some recommend, for the transfer, zinc plates in preference to stone. The invention of Zincography is said to be due to the late Mr Eberhard of Bavaria. It is, however, a mere application of lithography to zinc plates, with some modifications of the etching, printing, &c.

Transfers of stone, copper, and steel engravings, as well as of type-printing and woodcuts, to stone, are best made on the usual transfer-paper already described. The ink for transferring drawings and writings from stone consists of a stick of lithographic ink, melted down on the slab, and thinned when required with a small quantity of oil of turpentine and some printing-ink. It is put upon the transfer roller, which is frequently moved over the slab. The gum being washed from the stone, and the old ink removed with oil of turpentine, the stone is wetted and inked with the transfer-ink, and the impressions are taken on very slightly damped transfer-paper. To make this paper, mix three parts of the best wheaten flour, of the consistency of shoemakers' paste, with one part of finely ground plaster of Paris, and a very little dissolved patent glue, to prevent the ground from breaking when printed; then strain the mixture in spoonfuls into a common jar through a double fold of fine muslin, pressing it gently through with the back of the spoon; and when cooled, spread it with a flat camel-hair brush over half-sized thickish paper, which, when dry, may be laid aside and stored for future use.

The ink used for making transfers from copper, steel, and pewter plates, is composed of two table-spoonfuls of varnish, $1\frac{1}{2}$ parts tallow, 3 parts brown soap, 5 parts shell-lac, 4 parts brown wax, 5 parts black pitch, and $2\frac{1}{2}$ parts of powdered lamp-black; the whole is melted and heated until it takes fire, and is allowed to burn for fifteen minutes, being kept altogether for forty minutes on the fire: it is then formed into sticks or balls, rolled with the hand; and should become, when cold, as hard as pitch. If not so hard, more wax and pitch should be added; some add a half part of Venetian turpentine when the wax is cooling.

The plates are then warmed on the printer's gas-stove, and inked up by the copper-plate printer in the usual way; the coated paper is slightly sponged on the back, and the impressions made on the coated side. A moderately warmed stone is then placed in the press; the transfer impression having been previously put between damped blotting-paper, is now put on the stone (yellow stones are better for transferring than gray or blue ones), and the transferring proceeded with in the same manner as described in the transferring of writings and drawings done with the pen on lithographic transfer-paper. If any of the lines on the engraved plate are very deeply cut, it is advisable to put the transfer impression, before being transferred, between some sheets of slightly damped blotting-paper, and pass it with a moderate pressure through the press. Thus, any superfluous ink will be removed, and the lines which may have too much ink are prevented from spreading.

Very striking results have been obtained by this process; and its value to publishers is well known, as the original plates are not worn out, and the expense of printing from the stone is cheaper than printing from copper and steel, besides being a great deal cleaner. Maps and engravings of any kind may, in this way, be patched or enlarged, or divided into separate pieces, to suit any size of book or paper. Transfers from copper-plates, from line-drawings on stone, writings, woodcuts, and letterpress, may all be transferred together on one stone, and printed on the same sheet. It is pretty obvious, that thus an infinite variety of

Litho-
graphy.

Litho-
graphy.

new forms may be obtained from an exhausted stock of old plates, a circumstance occasionally of great value.

Tinted Lithographic Drawings.—For brevity's sake we shall only describe the production of drawings with two tints, as, from this description, the mode of printing a drawing with more tints will be easily understood. The principal drawing is done upon a grained stone in chalk, and should be very bold, more like a sketch on tinted paper; the middle and finer tints being left out. The stone is then etched, and two impressions are taken, so that when each of these is put upon a roughly-grained stone and passed through the press, counter impressions will be found upon the stones, revealing the drawing quite distinctly. After having cut in the outlines with a sharp-pointed graver or steel needle, the artist covers those parts on the two stones which are not to appear in the one or the other colour, as well as the margin of the two stones, with a brush containing acid and gum. The stones are then warmed, and a composition containing the same ingredients as soft chalk, with double the quantity of soap and three times the quantity of tallow, is rubbed over it with a bit of coarse flannel, until it is of a dark grayish-brown colour. From having been previously cut in, the outline comes out very distinctly. The artist can now produce an effect similar to crayon sketches which have been washed in with two separate colours. Those portions which have been rubbed in, and which appear dark grayish-brown, form the middle tint, and the scraper may be used to reduce the colour of the tint where the gradation of colour is desired; the darkest portions being laid in with lithographic ink, and the blending together done with chalk, brush, pen, and scraper, so as to produce in many places the effect of shadings of one colour over another. Any one looking at Louis Haghe's work on the *Architecture of the Middle Ages in Germany and the Netherlands*, Roberts' *Holy Land and Egypt* drawn by Haghe, or Simpson's drawings of the Crimean war, and the tinted lithographs of the British fleet, will understand the important and charming results of this branch of art in which Britain stands unrivalled. The stones, when ready, require to be very strongly etched.

We may mention that those studies of heads and figures as drawn by Jullien and Lasalle, of Paris, are tinted in a different style. An impression is taken from the drawing on stone, and passed, when fresh, over a roughly grained stone; then on the roller is put some light brown Brunswick black, or asphaltum, which must be worked on the slab until uniformly spread over the roller. The stone with the counter impression upon it, is, in a dry state, rolled over with the Brunswick black until the whole stone is covered with an even light-brown colour, through which the drawing is distinctly visible. After some hours, the covering becomes quite hard, and the artist can scrape out the lights of his drawing so as to give it the appearance of a crayon drawing which has been touched by a white crayon. The effect is very beautiful; and the two artists above mentioned stand pre-eminent for this style.

Chromo-Lithography is executed in a similar manner, with this difference, that the first drawing is generally only in outline, and is used merely to take as many impressions on stones as are required for the several colours of the painting to be copied, so as to bring out on each stone precisely the same outline, and thus to enable the artist to fill in on every stone the proper colour, and to enable the printer also to have proper register.

Presses, rollers, varnishes, &c.—Lithographic presses are of a great variety of construction, so that we can only glance at the chief points in their mechanism. The scraper is a wedge-formed plate of steel or boxwood, fixed to the bottom of the platten, with its edge downwards, and properly adjusted. The table on which the stone with the paper for receiving the impression is placed, and on which the tym-

Litho-
graphy.

pan is brought down, is, by means of a handle or wheel, brought upon the metallic moving roller and under the scraper, and the pressure is gradually continued from one end of the stone to the other; when it has passed through the press, the scraper is lifted, the moving table brought to its original place, and the printed sheet removed.

The *Lithographic steam-press*, although a very ingenious invention, has not benefited lithography in the same proportion as the steam-letterpress has letterpress printing. The self-acting lithographic steam-press of Sichel, of Berlin and Vienna, patented in this country, is a triumph of ingenuity, but it has not produced any work which the common steam-letterpress could not have done as well.

The *rollers* for printing may be made of different lengths, from 6 to 24 inches long, and $3\frac{1}{2}$ to 5 inches in diameter. They are made of wood of the alder and lime tree, with wooden handles to project and hold by; the roller is then covered with several complete turns of flannel, well stretched and fastened by sewing at the extremities near the handles; the whole is then covered with calf-skin, sewed with great care, so as to fit tightly, and laced near the handles. For printing chalk, tints, and colours, skins of different preparations are required. Hollow metallic rollers, covered with flannel and calf-skin, are in use on some parts of the Continent, where they are preferred to rollers made of wood.

The best *varnishes* for making the printing-ink are boiled from old linseed oil, of different degrees of strength—thin, middle, strong, and very strong varnish;—for printing with gold-leaf, bronze, and dusting colours, the very strong varnish is required. For writings, maps, and music, common calcined lamp-black is ground with the varnish; some hard blue is added to improve the colour, and to make the ink dry in a short time; for chalk ink, Paris black is used instead of the common lamp-black. For *tinting and colour-printing*, colourless, or bleached varnish must be used, as otherwise the purity of the colours will suffer.

Printing.—After the stones containing the writings or drawings in chalk, and those used for tinting or colour-printing are etched, and the preparation has become dry, the stones may be put into the press and properly fixed. To prevent a stone containing drawings of any value from breaking, it should be backed to another stone,—or what is better, to a slab of Aberdeen granite. This is done by a mixture of plaster of Paris and cold water, of the consistency of syrup, a pretty thick coating of which should be spread evenly and quickly on the slab; the stone containing the drawing is placed into this layer, and moved in all directions until the plaster of Paris becomes quite hard, which will take place in a very short time. After the printing is accomplished, the stone can be quite easily removed from the slab, by using a chisel, and by giving some side strokes with a wooden hammer. The old dry plaster of Paris is now removed, and the slab is again fit for use.

Everything being ready, the gum is entirely washed away with a soft Turkey sponge and water; the writing or drawing is then obliterated by taking a clean sponge and oil of turpentine, to which may be added, at pleasure, a few drops of sweet oil, after which the stone must be cleaned with water. An entirely clean sponge (or for writings, a bit of soft canvas manufactured for the purpose) is now required for the printing. The stone is slightly wetted with this sponge, the printing roller, charged already with the proper ink, is passed repeatedly over the whole stone, and the writing or drawing will begin to reappear; the roller is again worked on the ink-slab, the stone wetted anew with the sponge, and again rolled over, until the writing or drawing appears in full strength. A sheet of damped paper (dry paper may be used for writings and drawings in line) is put on the stone, the tympan is let down, the scraper brought to its proper place, the pressure effected, and, by means of the handle, cross, or wheel, according to the style of

press, the table with the stone is slowly and equally drawn through to nearly the end of the stone, for which purpose the press requires to be set properly beforehand. The printer now relaxes the pressure, the table with the stone runs to its original place, the tympan is put back, and the impression is carefully taken up from the stone. The stone is then again wetted as before, inked in anew, the paper placed upon the stone, and further impressions are effected. When the stone is to be kept after the required number of impressions has been struck off, it should always be inked up with preserving ink, which is made by melting lard, tallow, and wax, in equal proportions, with a quantity of printing-ink. When about to be used, this preserving-ink may be thinned with some oil of turpentine, thinly spread on a roller kept for this purpose; it must then be properly turned on the slab, the writing or drawing is washed out with oil of turpentine, the whole removed with a clean sponge, and the stone wetted and inked in with this preserving-ink. A few minutes afterwards, when the turpentine has evaporated, a thin solution of gum-arabic is spread over the stone, containing a little sugar-candy to prevent the cracking of the gum by change of atmosphere. The stone will keep any length of time; but the preserving-ink should be renewed at least every twelve months.

The printing of tint and colour stones is treated in the same way, only the rollers, varnishes, and colours are different from those used for ordinary black and chalk printing. The printing of this class of work requires great skill and taste. Many of the lithographic printers of London, Paris, Brussels, Munich, Berlin, Vienna, and Dresden, are justly famed for their beautiful productions.

An engraved stone is printed by using a small wooden tapper or tampon, either round at the sides, flat below, with handle at top, or square, and the corners rounded off. This tampon is covered several times with a very coarse blanket, or coarse thick firm cloth fastened at the sides; the ink is then spread very thinly on the slab, the tapper is properly tapped into it, the gum is removed from the stone, and the drawing is removed with oil of turpen-

time; the stone is wetted, the tampon is tapped over the whole drawing, the stone cleaned with a bit of wet canvas, and finally a printing-roller is passed once or twice over the stone, which removes all impurities; a damped sheet of paper is placed on the stone, and the impression made as formerly explained. Some printers print engraved outlines or drawings done with thin lines entirely with the roller, which is a great saving of time. Other printers, again, ink an engraving with a large shoe-brush with long stiff bristles, which is rubbed on the ink slab to give it the ink required, by brushing over the drawing in all directions.

The only other branch of the subject requiring notice is the process of *Photo-lithography*, which is managed in the following manner:—Spread over a grained stone a solution of ether and bitumen of Judea, or asphaltum. When dry, lay the print or negative-photograph to be copied on the top of the stone, and then expose both in this way to the daylight for some time. Put the stone then in ether, which will dissolve off the stone the coating of bitumen on the parts that have been unaffected by the light under the dark parts of the print; whilst on the parts that have been acted on by the light, through the light parts of the print or negative, the bitumen having become insoluble, is undissolved, and when the stone is, in the next operation, placed by the lithographer under acid, in the usual way, these parts are protected from corrosion by the acid. The subsequent treatment is exactly similar to that of an ordinary chalk drawing. From the specimens which we have seen by photo-lithographers in Paris, Munich, and Rome, and from the very slow progress which has been made since their first impressions were exhibited a few years ago, few practitioners can hope, considering the difficulties of printing from stone, to see photo-lithography approach in their hands the perfection of those examples of photography exhibited at the Photographic Societies' Exhibitions of London and Edinburgh.

It is much to be desired, however, that some process may be invented for printing photographs with accuracy and facility.

LITHUANIA, a country of Europe, comprises the northern and larger portion of West Russia, and forms all the N. and N.E. part of the ancient kingdom of Poland. Area 112,000 square miles, and population about 5,000,000. It forms the present Russian governments of Wilna, Grodno, Minsk, Mohilew, and Vitepsk. The country is on the whole flat, and is for the most part covered with marshes and sand. The duchy of Samogitia and the banks of the Niemen, however, are fertile; the former of these producing a large quantity of flax. The mineral products are granite and pudding-stone; and iron is found, although in very small quantities. In winter the climate is excessively severe, while it is very hot in summer. Bears, wolves, elks, wild hogs, &c., abound in the forests; and the bison, or urochs, which occurs also in the Caucasus, may be found in the forest called Biala Vieja. The manufactures are of no importance, and the trade consists chiefly of exports of flax, timber, corn, wax, and honey.

In the *Chronicle* of Quedlinburg, A.D. 1009, we find mention is made of Lithuania; but little is known of it till the end of the twelfth century, when we find the inhabitants called "Lettoven." At a very early period they fell a prey to the Russians, who reduced them into a state of slavery and degradation. The consequence of this miserable condition was, that the Lithuanians had no decided position among the nations of Europe till the middle of the thirteenth century. At length, after long and bloody wars, they succeeded in gaining their independence; and, gradually encroaching on the Russian territories they extended their boundaries from the Niemen to the Dniester,

and from the Bug to the Dnieper. In 1230 Ringold assumed the title of Grand Duke of Lithuania. His son, Mendog, was baptized at Riga in 1252, but three years afterwards relapsed and became the sworn enemy of Christianity. Idolatry remained in the land for another century. The royal family became extinct with the death of Mendog's son in 1266, and Witenes, a young man about the court, succeeded in placing himself on the throne in 1282. He was succeeded by his son Ghedemin in 1315, who did more for his country than any of his predecessors, both by extending his conquests and preserving the religion, language, and customs of the inhabitants of the lands which he subdued. His son Olgerd, on his deathbed in 1381, at the instigation of his wife, became a member of the Greek Church. From Olgerd the power passed into the hands of Jagello, one of his younger sons; and on condition of his becoming a Christian, and of Lithuania being united to Poland, he received Hedvig the Queen of Poland in marriage. Jagello, together with all his brothers and sisters, and many of the nobles of his court, was publicly baptized in Krakau on the 14th of February 1386, and shortly afterwards was solemnly crowned King of Poland. In the following year he changed the magnificent heathen temple at Wilna into a Christian church, and at once induced thousands of his subjects to receive the Christian religion. From many circumstances, however, the real political union between Lithuania and Poland took place only gradually, although it had been formally declared at Wilna. Properly speaking, the union was not thoroughly established till the Diet of Lublin in 1569. Before Lithuania was annexed to

Litmus Russia, it had the following divisions:—Troki, Wilna, Novogrodek, Bzesk, Vitepsk, Polozk, Mohilew, and the duchy of Samogitia. In 1792 Russia took Mohilew and Polozk, and in 1793 the rest of the country.

Littleton.

LITMUS, or **LACMUS**. Lichens belonging to the genera *Roccella*, *Variolaria*, and *Lecanora* furnish the red, violet, and blue colours, commonly known as *archil*, *cudbear*, and *litmus*. The colouring matter does not exist ready formed in the lichens, but they contain from 7 to 12 per cent. of certain colourless acids, such as *erythric*, *evernic*, and *lecanoric*, which acids, when acted on by alkalies, form new acids, and these, on the addition of an alkali, produce a violet colour, and also a colourless neutral substance termed *orcin*. This is the colour-producing body; and when acted on by ammonia, it absorbs oxygen, and is converted into *orcein*, an azotized body with powerful tinctorial properties.

In preparing *archil*, *cudbear*, or *litmus*, the lichens are first cleaned from earthy matter, and are then made up into a paste with an alkaline solution, which in the case of *archil* is urine, with the addition of lime for separating the ammonia. By exposure for some weeks to the air, with occasional additions of the alkaline liquor, the paste assumes the characteristic colour of the lichen used. In this way *cudbear* is obtained from *Lecanora tartarea*, and *litmus* from the *Roccella tinctoria*; but in the latter case it is moistened with a mixture of carbonate of ammonia and carbonate of potash, and the colour is first red, and afterwards intensely blue. It is made up into small cakes, with chalk or plaster of Paris. The colouring matter of *litmus* is soluble in alkaline liquids, but only partially so in water and in alcohol. According to Kane, *litmus* consists of several principles, one of which is a red semi-solid body, soluble in ammonia with a purple colour, and termed *erythroleine*; secondly, a body named *erythrolitmin*, which forms crystalline grains of a dark red colour, and is soluble in alcohol, but not in ether; it becomes blue by the action of potash. Neither of these bodies contains nitrogen, but the third and chief component of *litmus* does so, and hence has been termed *azolitmin*. It is not soluble in alcohol or in ether, and only sparingly so in water; it has a brownish-red colour. It is soluble in ammonia, when its colour becomes blue; and when this solution is mixed with the salts of some of the metals, blue and violet lakes are formed.

Litmus is much used by the chemist for detecting the presence of acids, which turn it red; the blue colour is restored by the action of alkalies, so that when slightly red-dened, it may be employed as a test of their presence. The most convenient method of applying the test is by means of strips of unsized paper, tinged by an aqueous solution of *litmus*, and then dried. (C. T.)

LITTLE ROCK, a town of the United States of North America, capital of Pulaski county, and of the state of Arkansas, is situate on the right bank of the Arkansas River, in the centre of the state. It stands on a bold cliff about 50 feet high, which is the more prominent as it is the first rock met with in ascending the stream. The chief buildings of the town are—the state-house, made of rough cast brick, an arsenal, and penitentiary, besides several churches and seminaries. Excellent clay-slate and granite abound in the neighbourhood. *Little Rock* was founded in 1829. Pop. (1850) 2167, (1853) about 3000.

LITTLETON, SIR THOMAS, a famous judge, born about the beginning of the fifteenth century, was the eldest son of Thomas Westcote, Esq., of Devonshire, and the grandson, by his mother's side, of Thomas Littleton, Esq. of Frankley, in Worcestershire, whose name and arms he assumed. He was educated at one of the universities (probably Cambridge), and removing to the Inner Temple, London, became one of the readers to that society. Henry VI. appointed him steward or judge of the court of the palace, or marshalsea of the king's household; and on the

13th May 1455, king's serjeant. In this latter capacity being also a judge of assize, he travelled the northern circuit. His prudent conduct, and his high fame as a lawyer, secured the patronage alike of the Lancasterians and the Yorkists during their protracted struggle; and Edward IV., in 1462, the second year of his reign, tendered him a general pardon, and confirmed to him his offices of king's serjeant and judge of assize. In 1466, he was appointed one of the judges of the Common Pleas, and obtained a writ directed to the Commissioners of Customs for the ports of London, Bristol, and Kingston-upon-Hull, for the annual payment of 110 marks, to support his position, and of other small contributions to supply him with robes. In 1475 he was created, along with many of the first nobility, a Knight of the Order of the Bath. He died at Frankley on the 23d of August 1481, at an advanced age, and was buried in Worcester Cathedral, where a tomb, surmounted by a statue, was erected to his memory.

His famous work on *Tenures*, written in Norman French, is supposed to have been composed while he was judge of the Common Pleas, and to have been printed after the author's death, but at what date is uncertain. After passing through several French editions, it was published in English in 1539. Sir Edward Coke wrote a comment upon it, now well known by the title "*Coke upon Littleton*."

LITURGY is derived from a Greek word denoting the public service which citizens were bound to render to the state on certain prescribed occasions, but which is used in the Septuagint to express the public service of God. Liturgies may be of three kinds. Either they may form an *imposed* ritual, responsive in its character, and prescribed absolutely to minister and people for their invariable use, as is the practice in the Anglican and Lutheran amongst the Reformed churches; or they may take the form of a *discretionary* ritual, not responsive, and therefore supplied, as in France and Switzerland, to the minister alone, for his guidance in the matter and manner of worship, leaving variation as to the manner according to his judgment. This was the practice in the Church of Scotland during nearly a century of its existence, and it is retained in the Reformed churches of the Continent. The third method is that of *rubrical* provision, consisting of directions without examples, and omitting any precise forms of prayer. Of this character is the *Directory for Public Worship*, composed by the Westminster Assembly, which now forms the rule of worship in Presbyterian churches of Scotland and America. A fourth method of public worship—if there be such where no method exists—is that of entire freedom, such as has been claimed by some denominations since the days of the older Independents, who denounced all forms, as hampering the liberty of the individual. The expediency of any of these methods has been the subject of much and angry discussion at all the most decisive epochs of ecclesiastical history, and in this article we propose to limit ourselves to a short historical view of the various liturgies in the different sections of the Christian Church.

Amongst the Israelites, certain forms of prayer and praise seem to have been used from the earliest times. So far as we know directly from the Old Testament, the earliest prescribed forms were those according to which the priests were commissioned to bless the people, and the forms of prayer in presenting the first fruits and tithes. The Psalms of David also constituted a public liturgy; and some have argued from the metrical forms of various public prayers inserted in the record of Jewish history, that these also belonged to a prescribed service. The modern prayers of the Jews, however, many of which are attributed to the pen of Ezra, are certainly of far more recent date. They are only nineteen in number, and most, if not all, are later than the establishment of Christianity. That men were "taught to pray" in the days of our Saviour, seems evident from the

Liturgy.

Liturgy. circumstances which gave rise to the promulgation of the Lord's Prayer, and, whatever may have been the design of that formula, it is certain that it soon came to be used as a prescribed form in the Christian Church. (See Wheatley's *Illustration of the Book of Common Prayer*, and also compare Hind's *Rise and Progress of Christianity*.) From the incident in Acts iv. 24, it may be gathered that large masses of converts were able to join vocally in public supplication. In the earliest times of the Church, frequent reference is made to certain constituted prayers in general use (see Comber's *Scholastic History of Liturgies*), but in general these extended no further than to individual churches, and were arranged for local use by the ruling presbyter or bishop. Gradually, however, these spread from the metropolitan churches to the rural districts, and ultimately they became divided into great classes of national liturgies. Mr Palmer, in his *Origines Liturgicæ* (Oxford 1832), considers that all the liturgies of the primitive churches may be reduced to four: 1st, The great Oriental liturgy, which prevailed from the Euphrates to the Hellespont, and from the Hellespont to the southern extremity of Greece; 2d, The Alexandrian, which from remote antiquity has been the liturgy of Egypt, Abyssinia, and the country extending from the Mediterranean Sea towards the W. 3d, The Roman, which prevailed throughout the whole of Italy, Sicily, and the civil diocese of Africa; and 4th, The Gallican, which was used throughout Gaul and Spain, and probably in the exarchate of Ephesus until the fourth century. These, in the course of ages, were endlessly varied and diversified. From the whole history of these, it seems evident that there never was one catholic liturgy; that none of the liturgies now existing can be traced back to the apostles; but that formal prayers of some sort were used from the very beginning of the Christian Church. The Greek Church, at least so far as it is under the dominion of the Patriarch of Constantinople, possesses three liturgies, which are used at different seasons of the ecclesiastical year. That of Basil of Cæsarea is the longest, and holds pre-eminence in solemnity, as it is said also to do in point of antiquity. It is reserved for the most solemn festivals of the church,—Christmas, Lent, and Good Friday,—as well as for a few other occasions. The second bears very undeservedly the name of Chrysostom, being considerably later than his days. It is read on all the other days of the year except during a few days in Lent, when the *Liturgy of the Presanctified*, a composition of the seventh or eighth century, takes its place.

Amongst the Eastern sects a characteristic variety of liturgies prevails. The ancient Coptic Christians had as many as twelve different forms, and these still linger among the Ethiopians. They were,—1. *The Liturgy of St John the Evangelist*; 2. *Of the Fathers of the Council of Nice*; 3. *Of Epiphanius*; 4. *Of St James of Sarug*; 5. *Of St John Chrysostom*; 6. *Of Jesus Christ*; 7. *Of the Apostles*; 8. *Of St Cyriac*; 9. *Of St Gregory*; 10. *Of the Patriarch Dioscorus*; 11. *Of St Basil*; and, 12. *Of St Cyril*. Amongst the Copts, however, all the minor liturgies fell into abeyance, being discountenanced by the patriarchs; and the usage of the church came to be limited to the liturgies of Basil, Gregory, and Cyril. Amongst the Syrian Catholics, the Liturgy of St James is preferred, but numerous others are also found in use.

The *Breviary* contains the daily service in the Church of Rome. Originally it contained only the Lord's Prayer, with extracts from the Psalms, to which, very soon after, were added lessons from the Scriptures. The obligation to read it daily rests upon the beneficiary clergy alone; but on them it is imposed under pain of mortal sin. Although read only in Latin in the churches immediately depending on the Holy See, fragments of it have found their way into the vernacular of eastern tribes who at one time were in

close connection with Rome. Besides the *Breviary*, there is also the *Missal*, or volume regulating the celebration of mass. A tradition of the Romish Church ascribes its composition to the apostle Peter, but it does not appear to have been reduced to writing till the middle of the fifth century, and it owes much of its present matter, as well as nearly all its present form, to the genius of Pope Gregory the Great. The *Ceremoniale* may be designated a liturgy for the pope, embracing all that pertains to the various functions of his office, just as the *Pontificale* describes the various functions of the Romish bishops, and the *Rituale*, or *Pastorale* as it is sometimes called, contains directions for all the pastoral duties of the inferior clergy. The ancient *Gallican Missal* dates from beyond the days of Pepin, and is more closely allied to the liturgies of the East than to that of the Latin Church. The old *Spanish* or *Mozarabic Liturgy* consisted of the liturgy of Rome, mingled with the oriental liturgies of the Arian Goths, who overran the kingdom. Its use was suspended by the Council of Braga; and it was only saved from oblivion by Cardinal Ximenes, who reprinted it in 1500, and endowed a chapel and canons to use it daily in Toledo. The *Ambrosian Liturgy* is one of great antiquity, having been only edited and supplemented by the bishop whose name it bears.

The liturgies of the Reformed Churches are all compiled in the vernacular, the use of the Latin tongue having been abolished in worship as soon as it came to be recognised that adoration demanded intelligence. Luther, in 1523, drew up a liturgy for the use of the German Church; but as he had no desire to impose this as a form on all who held the same doctrinal views with himself, all the Lutheran countries have Lutheran liturgies of their own; but these agree in almost every essential particular. In Prussia, the form generally adopted is that drawn up in 1822, for the use of the cathedral church in Berlin. Calvin also drew up a liturgy, for the use of the Reformed Church of Geneva and elsewhere. The Genevan formula was published in 1543, six years before the first book of Edward VI., and while it retained many parts of Christian service which Calvinists now dispense with, it was the first to originate the idea of making the singing of psalms take the place of the vocal response on the part of the people. In its nature it was intended to be compulsory, but a provision was made for extemporaneous prayer and for special prayers on particular occasions. Calvin's *Daily Offices* were also composed as directions for family prayer; and these are used as a form of morning and evening prayer in several branches of the Reformed Church. In France, the Genevan liturgy long retained its hold supreme in the affections of the people. It was used in the earliest meetings of the Reformed congregations after their organization in 1555; and the last synod or national assembly of the French churches in 1569 issued instructions for preserving its purity. Various modifications have been made on it since the restoration of the Protestant worship, and new prayers have been introduced from other sources, in effect destroying its venerable character. In Scotland, although the liturgy had a short existence in the national church, yet during its continuance in use, it seemed in no way to offend the feelings of the people. John Knox died repeating the words of Calvin's *Daily Offices*. In 1562 was introduced the *Book of Common Order*, commonly termed *Knox's Liturgy*; and two years later its use was enjoined upon the Church by the General Assembly. It was drawn up after the model of the Genevan formulary, and was mainly intended for the readers and exhorters; although even they were invited to avail themselves of the latitude recommended to all the clergy. It is difficult to fix the precise period when the liturgy ceased to be used, but it perished when Knox's overshadowing greatness ceased to influence the practice of the Church. At present the

Liturgy.

Liverpool. worship of the Presbyterian churches in Scotland is guided by the *Directory for Public Worship*, issued by the Westminster Assembly, which contains directions, but no forms of prayer; but it is scarcely too much to say that in general throughout Scotland, the provisions of the *Directory* are almost entirely forgotten.

In England the *Book of Common Prayer* forms the liturgy of the Established Church. It is founded on the *King's Primer*, published by Henry VIII. in 1546; which, however, contained little more than the Creed, Lord's Prayer, Commandments, and Litany. This, during the reign of Edward VI., underwent two separate revisions, and the *Second Prayer Book of Edward VI.* approaches very nearly to the liturgy of the present day. After having been discontinued during the reign of Mary, it was again revived with the reign of Elizabeth, and received further improvements, especially in the selection of the lessons. Some alterations were introduced during the reign of James I., and consisted chiefly in the appointment of a

collect in the daily morning and evening service; the insertion of a prayer for the Royal Family in the Litany; and addition of questions and answers in regard to the Sacraments in the *Catechism*. In 1662 it was revised by both Houses of Convocation, and was sanctioned by act of parliament in its present form. The liturgy of the Scottish Episcopal Church has been, since 1712, the same with the *Book of Common Prayer*; with as little variation as circumstances will admit, except in regard to the Communion Office.

Of Dissenting liturgies, it is perhaps only necessary to mention Dr Samuel Clarke's *Reformed Liturgy*; the *Sunday Service* of the Wesleyan Methodists, prepared originally by John Wesley; and, on the Continent, the *Liturgy of the Unitas Fratrum* or Moravian Brethren.

See Kœcher's *Bibliotheca Liturgica*; Bingham's *Ecclesiastical Antiquities*; Adams' *Religious World Displayed*; Palmer's *Origines Liturgica*; and Baird's *Chapter on Liturgies*.

LIVERPOOL,

A BOROUGH of England, in Lancashire, and one of the greatest commercial towns in the world, is situate on the Mersey, along which it extends for nearly 6 miles. For 5 miles of this distance, a line or chain of docks runs parallel with the river, and from these docks, at intervals, streets extend at right angles, tolerably direct, to the extremity of the boundary. These are crossed by streets more or less parallel to the river; but as the town grew up rather suddenly, no great attention was paid to regularity. The boundary line, from where it touches the river at the S. to its termination at Bootle Bay, embraces a circle of about 8 miles. As yet the extremities are imperfectly filled up, but in some places the houses extend beyond the line.

History.

Local archaeologists have been eager to invest the town with the dignity of a remote antiquity; but their labours have not been very successful. In *Doomsday Book* the name does not appear, although sites within its present boundary are mentioned. Mr Picton, in his admirable paper on "Ancient Liverpool," contends that the place mentioned as *Smedone* must have represented Liverpool, and that *Smedone* is identical with Smithdown, now one of the southern streets. This, however, is not likely, for Smithdown was remote from ancient Liverpool, and on the south side of the Pool, then called Mersey Sea. The name has been a subject of unsatisfying contention; for although the final syllable *pool* is derived from the locality, *liver* is of doubtful origin. In early times the town was called indifferently *Lirpool*, *Litherpool*, *Lithpool*, and *Liferpole*. *F* and *v* were commutable; but, in the most ancient records, the name is written indifferently *Lithepol* and *Lithpole*. Mr Baines, in his *History of Liverpool*, is disposed to think that *lithe* must be accepted for sea, and thus the derivation will be the pool on the sea. Originally the place was only a small fishing village; for the Mersey, up to a very recent period, was remarkable for its supply of salmon and other fish. The first authentic record of the town is found in a charter of Henry II., in the year 1173, declaring that the estuary of "the Mersey shall be for ever a port endowed with all the liberties belonging to a port of the sea, and that the men of Lyrpul, near to Toxteth, may come and go from each side of the sea with their ships and merchandise free and without obstruction." It is supposed that his majesty, in this charter, had reference to the conquest of Ireland; for, not content with the bestowal of a barren privilege, he actually erected dwellings called burgage houses, the tenants of which were the primitive freemen of Liverpool. These houses con-

tinued to yield a rental to the crown up to the time of Elizabeth, and constituted, to a great extent, the dwellings of the inhabitants. In 1207 King John granted the town a charter, as follows:—

"Know ye, that we have granted to all our faithful subjects who have taken burgage houses at Liverpool, that they may have all the liberties and free customs in the town of Liverpool which any other free borough upon the sea has in our territories. And, therefore, we command you, that, securely and in our peace, you may come thither to receive and dwell in our burgage houses; in witness whereof, we transmit to you these our letters patent. Witness—Simon de Pateshill, at Winchester, the 28th day of August, in the 9th year of our reign."

On the apex of the promontory of some 40 or 50 feet above the river, a castle was erected at a very early period. Its erection is ascribed to King John, but it is supposed to have existed, in some form or other, before his time. The king subsequently granted the site of Liverpool to Fitzwarine, but it reverted, in the next reign, again to the crown. The "free customs" of the charter mean exemption from the petty customs; and thus, from that time to this, the freemen have been exempt from the payment of small dues. Henry III. extended their privilege by exempting them from tolls in all the ports of the kingdom; but all merchants frequenting the port of Liverpool were bound to pay due customs. Immediately after granting this charter, King Henry farmed the town to the freemen at L.10 per annum. Charters and privileges at that time, however, were easily set aside or violated with impunity; but from the reign of King John to that of Charles II., the crown claimed a right to these dues, and farmed them to various persons. In 1399 John of Gaunt leased the dues and all other profits, arising as well by sea as by land, for 57 marks. From that period the duchy of Lancaster became attached to the crown, and consequently all grants proceeded from the same source. A fee-farm of the town was let to various persons—at one time to the people of the town, at others to individuals; but in 1466 the value had increased to only about L.14 a-year. In 1528 it was estimated at not a greater value. A few years afterwards Henry VIII. considered that he had been defrauded by the corporation, and appointed an inquisition for investigating the matter. There was some reason for this, for the freedom of the town was granted to foreign merchants on the payment of a certain sum, which sum relieved them from the burthen of town-dues. The corporation, such as it was, also exer-

Liverpool. cised a monopoly, and excluded from trade in the town all who were not members of their municipal body. This, however, had but little effect in retarding the progress of the place; for, notwithstanding the favours of the crown, its prosperity positively declined from the thirteenth to the sixteenth century, from causes quite apart from local or royal measures. In 1346 there were 168 burgages, held at the rate of 12 pence annually; in 1429 these had been reduced to 148; and in the reign of Elizabeth, in 1655, they had fallen off to 138. The population may, therefore, be set down, at the last named period, as about 1000. So poor was the place that for 200 years it returned no member to parliament. The population nestled about the castle, forming no continuous street, but lining, at intervals, the roads or pathways, which were not paved before the fourteenth century. The first palpable step in advance taken by the town was in the reign of Charles II. A new world had then been opened to the enterprise of the old; and Liverpool invited to its port such trade as was created by the infant manufactures of Lancashire, Yorkshire, and Cheshire. As the plantations in America increased so did the trade of Liverpool; and from an early period her merchants took a prominent part in the slave trade. She sent out ships to Africa, conveyed their live burdens to America and the West Indies, and in return brought back to the Mersey the sugar, tobacco, and other produce of those regions. The English merchants and shipowners had competed successfully with the Spaniards and Portuguese; but it was not until 1708 that the first slaver was despatched from the Mersey. Having entered on the trade, they soon participated largely in it; for, in 1752, 101 Liverpool merchants were engaged in the slave traffic, 135 appertaining to London, and 157 to Bristol. The number of Liverpool vessels engaged in the American and West India trade was 106, and of these 88 were slavers. In due time this trade greatly increased; and that it enriched Liverpool may be inferred from the fact that the greater portion of the West Indies belonged to merchants of this place. This trade, however, like every other, was affected by war. It almost ceased during the French war of the eighteenth century, and the merchant ships unemployed were eagerly converted into privateers. At first the gain was immense; but subsequently the French predominated, and Liverpool suffered severely by the privateers of the enemy. On the return of peace, trade was resumed, but not with any accelerated force until the inventions of Arkwright and others created the cotton trade in Lancashire. The war of American Independence had the worst possible effect on the prosperity of Liverpool; and the late war of the French Revolution at first operated most adversely. Still, two circumstances obviated these bad effects. The great increase of population and trade in the United States of America created a demand for British manufactures, and these manufactures had nearly all to pass from the Mersey, which received in return the raw produce indirectly paid for them. At the close of the war Liverpool was still advancing, but not so rapidly as within the last 25 years.

Trade of
the port.

In 1750 Liverpool had only 20 sailing vessels engaged in the continental trade; now she has treble that number, and fleets of screw steamers, which constantly visit every port in the Mediterranean, and render the Mersey a medium of communication between France, Holland, Belgium, and America. The East Indies, too, have been opened to Liverpool enterprise. Since the alteration in the Company's charter, and in the amount of business done in the East, Liverpool stands next to London. Another trade she has almost monopolized—the Australian trade. Her clipper vessels are admitted to be the finest in the world, and, in consequence, the emigration to the antipodes is the largest

from this port, and the return cargoes the heaviest; for necessarily the freights are low, as more goods go than come, and cheapness induces shippers to send their wool here rather than to London, although London is the principal market. But Liverpool is now creating a wool market of her own.

The first authentic account of the number of vessels entering the port dates from 1577; and the following returns indicate at a glance the progress of the trade:—

Years.	Vessels.	Tonnage.	Dock Duties.
1757.....	1,371	...	L.2,336
1780.....	2,261	...	3,528
1800.....	4,746	450,000	23,379
1820.....	7,277	805,033	94,412
1830.....	11,214	1,411,964	151,359
1840.....	15,998	2,445,708	178,196
1850.....	20,457	3,536,337	211,743
1856.....	20,886	4,320,618	326,801

The custom-house revenue collected in the port was, in 1855, L.3,576,344, 2s. 8d., and 1856, L.3,824,177, 14s. 8d.; showing an increase of L.247,843, 12s. The last quarter of 1856 exhibits a comparatively further increase of L.118,581 over the corresponding quarter of 1855. The town dues now produce more than L.120,000 a-year, and there is another impost called light-dues, which produced in 1856 L.99,965, against L.86,182 in 1855. These light dues go altogether to the Board of Trade, and are disposed of as passing tolls. The greater number of vessels frequenting the port comes from the United States of America; for the great trade of Liverpool is in cotton, and the cotton supplied comes in largest quantities from the southern states of the Union. The following returns will give a correct idea of the progress of this trade. In 1770 there were imported into Liverpool 6037 bags 3 bales 3 barrels of raw cotton; but since the improvements of Hargreaves and Arkwright in spinning, the trade has greatly increased. Thus the importation was, in—

	lb.		lb.
1780.....	6,766,613	1830.....	261,961,452
1800.....	56,010,732	1840.....	583,400,000
1820.....	143,672,655	1850.....	685,600,000

In 1856 there were imported into Liverpool 2,028,850 bales of cotton.

A large trade is carried on in flour, grain, and corn. The imports of these in 1856 were—

Wheat, qrs. 1,370,152	Flour, sacks,232,704
Corn, do....897,407	Do. barrels,....1,138,260

Two-thirds of all this comes from America. The quantity re-exported is small. The total sugar imported in 1856 was 76,000 tons, of which 17,840 tons were from the British West India plantations, 18,555 from Bengal, and 19,996 from Brazil.

For carrying on a trade so large great facilities are afforded. In 1715 the first dock was constructed with an area of three acres and a half. This sufficed for forty-two years; but, at an interval of eighteen years, another dock appeared, and within a period of fifty years five additional docks were made. In 1826 the corporation filled up the primitive dock in order to erect the custom-house on its site. In consequence of this proceeding, and the rapid increase of buildings, none of the docks run inland, but all extend along and parallel with the river. From 1830 to 1842, eight new docks were opened; and from 1845 to 1852, not less than fourteen docks and basins have been added. The total water space afforded by the docks is 200 acres; and the quays measure 14 miles in length. The river wall is 5 miles 200 yards long; the total area of the dock estate is 712 acres.

No other port can present anything to be compared with the Liverpool Docks. One serious inconvenience however is, that running along the river wall, they interrupt the ap-

¹ This is the first year when goods were rated as well as ships.

Liverpool. proaches to the ferries, and when the gates are open, stop intercourse for a short time altogether. To remedy this an immense landing stage, constructed by Mr Cubitt, has been placed at St George's Pier, and this has not only promoted the comfort of passengers, but served as a very popular promenade. Another landing-stage has been constructed three times the size of the former one, at a cost of L.150,000. Means, too, are under consideration for facilitating approach to the ferries.

Until 1826 there were few warehouses on the dock quays. The warehouses are in general up the town, or at some distance from the quays. The inconvenience of this provoked a lively agitation among the merchants, and, through the great exertion of several members of the council, the Albert Dock was constructed and surrounded, like St Katherine's Dock, London, by piles of ponderous warehouses. Stanley Dock has since also been surrounded by warehouses, and the new Wapping Docks are to have the same advantage.

Extensive as the dock accommodation is, it is no longer adequate to the wants of the port. Several new docks are projected at the N. end, on land reclaimed from the bay, under a certain understanding with the Earl of Derby; and in 1854, the corporation became purchasers of the Birkenhead Dock and estates for a sum of L.1,143,000. But these docks, to be rendered available, will require a further outlay of L.800,000.

The constitution of the dock management has undergone some changes. The corporation having been the first projectors and supporters of the docks, were recognised as trustees of the estate. Under the act 51st George III. the committee consisted of twenty-one persons, all members of and appointed by the common council, and this continued until the passing of the act 6th George IV. 1825, when the dock ratepayers were first directly represented by returning eight members to the committee; the council electing thirteen, including the chairman, and the council having a veto on the proceedings. This continued until the act of 1851, by which a committee of twenty-four is appointed—twelve by the council, and twelve by the dock ratepayers. The committee appoint their own chairman and deputy-chairman; the chairman being, however, one of the twelve members elected by the council. The council have also a veto on the proceedings of the committee by a majority of two-thirds.

The care of the port is divided between the dock committee and the corporation. The latter constructed the lighthouse and built the Wallasey embankment, to prevent the sea encroaching on the district and impairing the channels leading to the river; and the former provide buoys, and a marine surveyor whose duty it is to note the shifting of the sandbanks, and give notice to the pilots and mariners.

Ship-building. There are several eminent ship-builders in Liverpool, but of late the greater part of the trade has been in repairing and in the building of iron ships. There are five building-yards on the Lancashire side of the river, and three on the other side. Those on the Cheshire side combine graving with building docks, and, although there are several graving docks on the Liverpool side, they are found to be inadequate to the wants of the port. As might be expected, a large trade is carried on in ships. In 1856, 694 ships of 328,991 tons were sold, and of these one-fifth were bought by foreigners.

Manufactures. Liverpool is a place of trade rather than of manufactures, and those manufactures which exist are more for the supply of local wants than for general purposes. An attempt was made to establish a cotton manufactory, but without success.

Political and social. The origin of the corporation, as we have already shown, was sufficiently humble. Deficient in strength itself, it sought to borrow power from neighbouring greatness, and of course shared the usual fate of dependants. When the

house of Molyneux proved unkind, the corporation became the client of that of Stanley; but to the former family it seemed most attached. Against both patrons it occasionally played off the chancellor of the duchy. When compelled or disposed to send representatives to Parliament, it sometimes ventured to nominate one, leaving a blank to be filled up by the predominant power of the day. There was, however, in the sixteenth and seventeenth centuries, a partial growth of independence. Individuals acquired wealth; out of riches grew local rivalry; and small enmities were as violent then as at a later period. The corporation was not at first perplexed by forms; all the burgesses assembled at the Market Cross, until the number claiming to be present proved rather too numerous. A common council was then resorted to, but in time this became self-elected. The freemen, until about 1820, retained the right of electing the mayor, but subsequently this was a mere formality. The council filled up the blanks left in their ranks by death or resignation, until 1836, when the Municipal Reform Act restored the body to popular election. In the earlier days of the corporation, heads of the houses of Stanley and Molyneux frequently filled the civic chair, the duty no doubt being performed by deputy. The corporation having been always dependent on the Crown, acquired a sentiment of loyalty which is still discovered in a customary toast at the mayor's table. In the civil wars, the town suffered from three sieges, but it had not much to lose. To the house of Hanover it paid marked devotion, and up to 1836 the predominant feeling in the council was Toryism. The new act divided the town into sixteen wards, and gave to each ward three members and one alderman. At the first election the liberals prevailed, but in a few years the opposite party obtained a majority, and have kept it ever since.

Before the Reform Bill, freemen only could vote for a member of parliament; but as their number was large, frequent and violent contests took place. With one or two exceptions, however, Tory candidates were returned. Mr Brougham, now Lord Brougham, contested the borough with Mr Canning, but lost the election. The freemen being artizans, dependent on the West India and other great interests, were necessarily exposed to certain influences, but in the end nearly all became venal; and at the election of 1830, the friends of the adverse candidates, Mr Ewart and Mr Denison, it is alleged, spent L.150,000. This great scandal hastened the reform measure. The Reform Bill continued the privilege of voting to the freemen, and, as usual, they aided the Conservative side. Under the provision of the act, however, their numbers are fast decreasing, and even now a contest is doubtful.

Next to London, the corporation of Liverpool is decidedly the richest in the kingdom. At first her income was miserably small, and centuries passed without improving it; but in 1777 the corporation purchased from Lord Molyneux, for L.2250, his reversion, expectant on the determination of his lease in the town dues, and these rose gradually from L.20,000 a-year to L.120,000. The income of the corporation is also derived from land within the town, from markets, and from police rates; the whole estimated at L.268,000 for 1857. The claim to the town dues has often been questioned. A case was tried in the Court of King's Bench in 1831, and decided in favour of the corporation; but in 1856 Government brought in a bill to abolish them. Great resistance being offered, a select committee was appointed; it heard evidence, but made no report. The people of Manchester are opposed to these dues, and it is believed that ultimately there must be a compromise. The dues consist of small sums, hardly appreciable in amount, collected on merchandise. The dock-rates belong to no special interest, being devoted not to demands, but simply to interest of money borrowed, and the cost of working.

Liverpool.

With the increase of trade and wealth the mode of doing business underwent a great change. At the beginning of the present century the merchant had his counting-house and warehouse behind his dwelling-house. These mansions may now be seen in Hanover Street, Duke Street, Seel Street, and others, bearing still in their architecture evidence of cost and taste, although now mostly devoted to meaner uses. Thirty years later the mercantile offices began to gather about the Exchange; mean buildings were transformed into lordly edifices; and as much as L.600 or L.800 a-year is now (1857) paid for a suite of rooms on a single floor. Such rents are, of course, temptations to an increase of buildings; and in 1856 as much as L.47 a square yard has been paid for building land near the town-hall. All the opulent classes live in the environs. Up to the year 1833 New Brighton was a sand-hill, without a single tenement on it; now it is covered with villas. The villas cover the hills and crowd the gorges, which extend from the Red Noses to Rock Ferry; while on the Lancashire side, Aigburth, Allerton, Woolton, Wavertree, Old Swan, Knotty Ash, West Derby, Walton, Crosby, Litherland, Waterloo, and Bootle, have been entirely occupied by the mansions and villas of the opulent people of Liverpool.

Public buildings.

Although the old corporation admitted of no popular element, they did much in promoting the comfort and prosperity of the town. They gave 40 acres of land for the construction of docks; demolished the old castle, and placed a handsome church on its site; opened new markets; widened narrow and all but impassable streets; contributed to the building of the custom-house; erected several very handsome churches; and lent their aid individually to the establishment of many charitable institutions. Formerly the markets were held in the open streets, which were exceedingly narrow and inconvenient. Originally the conceptions of the council were not very large; and, naturally enough, when they provided markets they were very small ones, in the vicinity of the streets where the articles were formerly exposed for sale. The fish-market and the shambles were, therefore, placed in the neighbourhood of Castle Street; but these proving inadequate to the wants of the population, St John's Market, one of the largest in the world, was opened in 1822. It is 123 yards long, 45 wide, and embraces an area of 8235 square yards. The architecture is substantial though not ornamental. The roof is supported by 116 cast-iron pillars, and the market is lighted by 248 windows. Subsequently St James's Market at the S. end, and St Martin's Market at the N. end of the town were opened; and the corporation have added one market in Gill Street. But all these markets, with the exception of St John's, are indifferently attended; for the number of greengrocers has amazingly increased, and, as in London, bring the marketable necessities of life to the door of almost every inhabitant. The wholesale butchers and cattle-dealers always held their market outside the town; and some years ago they constructed a very large and efficient market at the Old Swan, 3 miles from the borough.

One of the waterworks—the Bootle—was commenced in 1797; the Harrington Company's works, on a larger scale, followed soon after; but as the supply from these works was scanty, and utterly insufficient in cases of fire, an additional supply of water was obtained by sinking a well in Green Lane, in the township of West Derby. Complaints however continuing; in 1847 the corporation purchased the whole of these works for about L.800,000, and soon afterwards obtained an act of parliament for constructing high-service waterworks at Rivington Pike, a few miles beyond Bolton. The distance from Liverpool is 26 miles; and the water was brought thence into Liverpool for the first time in January 1857.

Liverpool.
Town-hall.

The present town-hall, a noble structure, stands nearly on the site of the original Market Cross. The primitive structure was a thatched edifice, erected on arches, somewhat after the fashion of the present town-hall of Chester. Above were the council-room and assembly-room, and the space underneath was intended to be used as an exchange. In 1754 it was opened with great *éclat*; but the arcades beneath being dark, the merchants declined to use it, and still continued to assemble on an open place in the street. In 1795 the building was consumed by fire, but was restored two years afterwards; the interior being pretty much what it is now. The present dome and cupola were completed in 1802, and the projecting portico and its rustic arcaded basement were added in 1811. The interior of the building is very fine. There are a spacious hall, a council-room, treasurer's office, and town-clerk's offices, on the basement story. A very splendid staircase leads to a suite of drawing-rooms, a very fine dining-room, an immense ball-room, with a smaller one attached. On the first landing of the staircase stands Chantrey's statue of Canning, considered one of that great artist's masterpieces; in the reception-rooms is a portrait of Canning by Lawrence, and one of George III. by Shee; and also portraits of the Duke of Kent, George IV., and William IV. In the council-chamber are portraits of various gentlemen who have passed the mayorial chair; the last taken being that of Mr William Wallace Currie, the first mayor of the borough under the Municipal Reform Act. The town-hall is made, with great propriety, to form one square of the exchange. This noble pile of building was commenced in 1803. The cost was estimated at L.80,000; and although no one was allowed to take up more than ten shares, the whole sum was subscribed in less than two hours. The building was completed in 1809, at the cost of L.110,840. It forms three sides of a square, the fourth being formed by the town-hall. The inclosed area is 197 feet by 178, and has in the centre a bronze monument in honour of Nelson, erected in 1813, at a cost of L.9000. It was designed by M. C. Wyatt, and executed in bronze by Westmacott.

The mercantile offices which have sprung up around the Exchange are remarkable for their architectural beauty, as well as for their convenience. Water Street, from the town-hall to George's Dock, presents a succession of such buildings. On the site of the old tower, the last remnant of the Castle, have been erected the Tower Buildings,—a mass of counting-houses, ornamented towards the river by an Italian tower, now used as a semaphore telegraph station. Fenwick Street, at right angles with Water Street, presents a succession of buildings equally beautiful. The Corn Exchange is in Brunswick Street; and in the same street is the Union Bank, a perfect architectural *bijou*; and a little further on, in James Street, at the top of Fenwick Street, is the North and South Wales Bank, equally entitled to notice. In Castle Street stands the Branch Bank of England, constructed by Mr Cockerell; and in the same street the Commercial Bank Buildings, erected after Mr Cunningham's design. North John Street, which runs parallel with Castle Street, is entirely devoted to offices; and in Dale Street are situated the Royal Bank Buildings, remarkable for boldness of design. The custom-house, which stands at the foot of South Street, was built after a design of John Foster, at the cost of L.283,804. The estimate was L.175,000; and although the building is an imposing one in appearance, it is regarded as not fully answering its purposes. In front of it is a bronze statue of Huskisson, by Gibson. Part of the custom-house is used as a dock-office, and another part of it as the post-office; for neither of which is the building particularly suitable. To the E. of the custom-house is the Sailors' Home, which is admirably adapted to the intended object of the Marine Board, and for a sailors' dépôt.

Liverpool. Lord Street, Church Street, and Bold Street boast very splendid shops. These streets are the most fashionable resort. The shops compete in extent and grandeur with those of Regent and Bond Streets, London, and in one or two instances are pronounced superior. At the extremity of Bold Street is one of the finest churches in Liverpool,—St Luke's, from a design of Foster, one of the discoverers of the famous marbles; and higher up, in Hardman Street, is the Blind Asylum and the Philharmonic Hall. The portico of the Blind Asylum chapel is a fac-simile of that of Jupiter Panhellinus of Ægina, after the design of Foster. This hall cost £37,000, was built after the design of Mr Cunningham, and is unquestionably one of the most admirable music halls in the world. It is lighted by an ingenious plan of concealed gases under the ceiling; it will accommodate 3000 people; and is admirably ventilated. The Philharmonic Society embraces the wealth and fashion of Liverpool. It gives from a dozen to twenty concerts in the year, and at these concerts, from time to time, appear all the great *artistes* who visit England. Subscribers only are admitted to the boxes and stalls; but spacious galleries, capable of containing 1000 persons, are open to the public at prices varying from one to five shillings each. A very beautiful little chapel, belonging to the Unitarians, stands contiguous to the last-mentioned building; and in the vicinity there are several other chapels, including that of the Blind Asylum.

When Liverpool had completely emerged from its obscurity, laudable efforts were made to provide for the amusement and intellectual improvement of the people. The Athenæum Library and News-room owes its origin, in 1799, to the celebrated Roscoe, who was a native of Liverpool; and the Lycæum was built in 1804, when the old Liverpool Library was removed to it. The Royal Institution, founded in 1814, was intended for the instruction of the public, by the delivery of scientific and literary lectures, the establishment of public schools, and the formation of a museum of natural history and works of art. A news-room was also established in the Union Buildings, Duke Street; but the great news-room of the town is that in the E. side of the Exchange Buildings, to which subscribers are admitted by the annual payment of three guineas each. The room above it is also a Lloyd's room, devoted exclusively to the underwriters. The subscribers to the general news-room number more than 3000. The Athenæum Library, containing many valuable works, was, until recently, not a lending library; but in 1856 it was resolved that subscribers should be permitted to take out works for reading at home. The Lycæum Library has always been a lending library, and is unquestionably one of the largest and best conducted in England. There are also several private libraries of considerable extent in the town. The Royal Institution has a theatre for lectures, a gallery of ancient art, a museum of considerable value, to which the public are admitted every Monday, and a school of high repute, but which is no longer under the control of the members of the Institution. A free library was established here in 1852. (See article LIBRARIES.)

In Lime Street is the London and North-Western Railway Station, which owes much of its architectural attraction to the liberality of the town-council, who contributed largely to the cost. Opposite to it St George's Hall stands out boldly in a large open space on the brow of a descent; and when the Free Library is built on the north side, a magnificent place will present itself for ornament and recreation. St George's Hall is a massive pile of building in the classical style of architecture, designed by the late Harvey Lonsdale Elmes, and after his decease, carried out by Charles Robert Cockerell, R.A., of London, the professor of architecture to the Royal Academy. The ground on which this ornament to Liverpool has been erected slopes down considerably to the W.; and a plat-

form has been built containing a number of apartments, and an extensive apparatus for warming and ventilating the building above. On this basement, at the south end, a magnificent portico, with a double row of Corinthian columns, eight in front and four behind, and a pediment filled with sculpture, rises from an extensive flight of steps, forming the principal feature of the building. At the N. end a semicircular arrangement of eight attached columns incloses a hall, which appears to be the natural entrance to the edifice, and is so used when concerts are given. But there are three other entrances more generally available at the E. side, under a colonnade of sixteen pillars, forming what is called the east portico, also approached by a handsome flight of steps. Considering this to be the main building, the wings N. and S. are carried out with square pillars; the intercolumniations being built up so as to form the outer walls of the apartments within. On these screens it is proposed, at some time, to place statues and bas-reliefs on the panels between the pillars. There is no pediment on this side; but above the main façade there is an attic which extends over the whole building; and a second attic of considerably greater height, to cover the roof of the principal room which has given the name of St George's Hall to the whole structure. This fine hall, intended for public meetings and concerts, is 169 feet long, 74 feet wide on the floor, with galleries on each side 13 feet in depth, and is 84 feet high. The ceiling is semicylindrical, divided by arching and longitudinal bands into panels of various shapes and sizes, which are profusely decorated with plaster ornaments in relief, upon faintly coloured grounds, in the style of the modern continental *Renaissance*. Tritons and mermaids, tridents, masks, caducei, fasces, various coats of arms, St George and the Dragon, are scattered in profusion over the vault, which is supported on each side by five lateral arches springing from six columns of polished red Aberdeen granite, and massive piers which divide the galleries into deep recesses. On the western side these recesses are occupied by five lofty windows, 18 feet 6 inches high, and 8 feet 7 inches wide. The capitals of the columns are plaster, painted to imitate the granite shafts, it having been contemplated at one time to make them of bronze. The frieze of the entablature above them is curvilinear, and also painted to imitate red granite. The spandrels of these lateral arches are decorated with colossal figures, in alto-relievo, of Prudence, Fortitude, Science, Art, Justice, and Temperance, in duplicate, and principally copied from Raffaele's designs of these subjects in the *Stanze* of the Vatican at Rome. Prudence resembles a figure by Michael Angelo. On the floor, which is a beautiful specimen of Minton's encaustic tiles, inscriptions in Latin and English, referring to the figures above, are worked in so as to furnish both ornament and instruction. A portion of this floor, all round the room, is raised about two feet, to receive the warming and ventilating apparatus. Flights of steps at each end of the hall lead to the Crown Court at the S. end, and the Civil Court at the N. These entrances are between pillars of grey granite supporting an architrave, over which there is a semicircular opening, through which the architect, Mr Elmes, contemplated a vista of the whole length of the three compartments from the back of each court—a length of about 300 feet. His object has been defeated by his neglect to provide a situation for the organ, which is one of the finest in the world, built by Willis, under the superintendence of Dr S. S. Wesley, and is now placed on a circular platform occupying the N. end of the hall, and obstructing the view of the entrance into the Civil Court. Semicircular windows, 33 feet in diameter, concentric with the ceiling, are introduced at each end. There are three entrances on each side, closed by folding gates of bronze, from the corridors, corresponding with the three outer doors

Liverpool. under the eastern portico or colonnade. Ten bronze pendants, of elaborate workmanship, containing double circles of gas jets in the form of stars, light this splendid hall. The recesses on each side of the hall are converted into galleries over the corridors, in front of which balustrades of coloured marbles and Derbyshire spar have been introduced. Coloured marbles are also introduced as panels and other decorations of the walls below the galleries. Here also are niches for statues of distinguished persons;—George Stephenson the engineer and Sir Robert Peel are already placed. The courts are quadrangular apartments, divided as usual for judges and counsel, witnesses and jury, with a dock for the prisoners entered from below, in connection with the cells in the basement of the building. At the back of the judges' seats are retiring-rooms, and along the eastern side, in two stories, a grand jury-room, a library, refreshment and robing rooms, and all the usual accommodation for the persons attendant upon the civil and criminal proceedings of the county. This portion of the building forms the base of a fine screen of square pillars similar in size and character to the colonnade on the eastern side, and, from the slope of the ground, gives by far the most imposing view of this great structure. Over the north hall there is a small circular concert-room, on which great expense has been lavished in a profusion of elaborate ornament.

This magnificent pile of buildings is pronounced by general consent to be the finest in Great Britain. The circumstances out of which the building of St George's Hall arose were as follows:—It had been resolved to build a music hall by subscription, and the corporation gave the land in Lime Street for that purpose, but a sufficient number of subscribers did not come forward. In the meantime, the assizes in 1835 were transferred from Lancaster to Liverpool, and the Sessions House being unsuitable, the corporation resolved to build new courts. Enlarging their view, the council at once superseded the music committee, took the charge of the building on themselves, and after examination of various places, resolved to have two assize courts, a council-room and a common hall under one roof; and this has been accomplished so well, that the common hall has become the most elegant council-room in the world. The first estimate of the architect was L.85,000; but it is believed that the work when finished will cost L.200,000. Mr Elmes died while the building was yet a skeleton, and as he left his friend Mr Robert Rawlinson, C.E., in charge, that gentleman accomplished what was considered impracticable, by turning the arch of the roof with hollow bricks. The assizes are now held here, and concerts are being given three or four times a-week. The council has appointed organists of the highest reputation

at L.350 a-year, to preside at the organ; and organ performances at small charges are given twice, sometimes three times a-week, to crowded audiences. **Liverpool, Charles Jenkinson.**

In addition to the St George's and the Philharmonic Halls, there are three other large concert-rooms in the town; there are four theatres, all well attended; and among the educational institutions, in addition to those already mentioned, are the Mechanics' and the Collegiate Institutions, both elegant and convenient buildings.

The population of the old borough in 1801 was 77,653; in 1811, 94,376; in 1821, 118,972; in 1831, 203,572; in 1841, in the new borough, 286,487; and in 1851, 376,065.

The usual rate of increase from 1851 to 1857 will have augmented the population to more than 400,000, and latterly it has gone on in an accelerated ratio. Proof of this is derived from the fact, that the number of new houses erected in 1855 was 1355, while in 1856 it was 1703; and the total number from 1838 to 1856 was 27,967. The annual value of the property assessed was L.1,461,577, and the local taxes assess at from 6s. to 7s. in the pound.

The paving, cleansing, sewerage, and lighting, are under the direction of the Health Committee of the council, assisted by a borough engineer, a surveyor of buildings, an inspector of nuisances, and a medical officer. In 1830 Liverpool was one of the most unhealthy towns in England; now it is one of the healthiest. The supply of water is under the care of the Water Committee, and in 1856 the water rate produced L.76,000, being L.15,000 above the expenditure.

Before 1836 Liverpool was protected only by a few de- **Police.** tective officers and a nightly watch, but under the Municipal Reform Bill an efficient constabulary force was established. It now consists of about 900 men for docks and town, both under one head constable. The borough gaol formerly stood in Great Howard Street, but in 1854 a new and spacious gaol was opened at Walton, 3 miles from the town.

The charitable institutions in Liverpool are numerous and well supported. There is a large workhouse generally containing 1700 paupers; an industrial school with about 900 children; three large hospitals; three dispensaries; and one eye-and-ear infirmary.

According to Mr Horace Mann's summary of the census, **Religion and education.** there were in Liverpool in 1851, 121 schools, in which 35,171 children were being educated, of which 82 schools, containing 25,963 children, were supported by religious bodies. There are in the town two parochial charges,—St Peter's and St Nicholas,—and 46 other churches belonging to the Established Church, 53 Dissenting chapels, 2 synagogues, and 12 Roman Catholic chapels. (W. J. W.)

LIVERPOOL, a seaport town of Nova Scotia, capital of Queen's County, on the right bank of a cognominal stream, near its mouth, 75 miles S.S.W. of Halifax; N. Lat. 44. 3., W. Long. 64. 42. It is regularly laid out, and contains several good public buildings. The harbour is commodious, but the bar admits only vessels of light draught. Timber and dried fish are exported in large quantities to the West Indies and the United States. In 1851, 84 vessels, of the aggregate burden of 9808 tons, and 104 of 12,640 tons, cleared at the port. The exports in that year amounted in value to L.30,392, of which to the value of L.23,049 were sent to the West Indian Islands. Pop. of county (1851) 7256.

LIVERPOOL, a seaport-town of New Brunswick, capital of Kent county, on the N. side of Richibucto Harbour, 45 miles S.E. of Miramichi; N. Lat. 46. 43., W. Long. 64. 54. It has a safe and commodious harbour, and an increasing trade in timber and deals. Pop. of county (1851) 11,410.

LIVERPOOL, CHARLES JENKINSON, first Earl of, was the eldest son of Col. Jenkinson, the representative of a family which had been settled at Walcot, near Charlbury, Oxfordshire, for above a century. Mr Jenkinson received his education at the Charter-House School and at the University of Oxford. In early life he published *Verses on the Death of Frederick Prince of Wales*; a *Dissertation on the Establishment of a National and Constitutional Force in England, independently of a Standing Army*; and a *Discourse on the Conduct of Government respecting Neutral Nations*. In 1761, having obtained an introduction to the Earl of Bute, he became one of the under-secretaries of state, and in the same year was returned to parliament for Cockermouth. In 1763 he was appointed joint-secretary to the Treasury; and having shared the marked favour of his majesty George III. with Lord Bute, he, on that nobleman's sudden retirement from office, became a conspicuous member of the party then commonly called the King's Friends. On the accession to power, of the Rockingham administration, in

Liverpool. 1765, he resigned his public appointments; but about the same period he was nominated auditor of accounts to the Princess-Dowager of Wales. In 1766 he was appointed a lord of the Admiralty by the Grafton administration; and the following year he became a lord of the Treasury. Under Lord North's government new honours awaited this steady aspirant for promotion. In 1772 he was appointed one of the vice-treasurers of Ireland; and in 1775 he was allowed to purchase the patent office of clerkship of the pells in that country. He afterwards succeeded Lord Cadogan as master of the mint; and in 1778 he became secretary-at-war. In 1783 he became a member of the Board of Trade; and in 1785 he published his *Collection of all the Treaties of Peace, Alliance, and Commerce, between Great Britain and other Powers, from the Treaty of Munster in 1648 to the Treaties signed at Paris in 1783*. In 1786 he was made chancellor of the duchy of Lancaster; called up to the House of Lords by the style and title of Baron Hawkesbury of Hawkesbury, in the county of Gloucester; and appointed president of the Board of Trade. In 1796 he was advanced to the dignity of Earl of Liverpool. His lordship was twice married, and had two sons and a daughter. After obtaining his earldom, he rarely quitted his retirement; but whenever he spoke in the House of Peers, the extent and accuracy of his information, particularly on commercial subjects, procured him marked attention. In 1805 he addressed a letter to the king on the coins of the realm, containing a concise and distinct statement of most of the facts deserving of notice in the history of British coinage. He died 17th December 1808.

LIVERPOOL, Robert Banks Jenkinson, second Earl of, son of the preceding, was born 7th June 1770. At an early age he was placed at an academy at Parson's Green, near Fulham, where he remained until his thirteenth year; he was then removed to the Charter-House School, where he continued between two and three years; and soon after leaving the Charter-House, he was entered as a student at Christ Church College, Oxford, where he became acquainted with Mr Canning. About the period of the breaking out of the French Revolution, Mr Jenkinson paid a visit to Paris, and was in that capital when the Bastille was demolished. Soon after his return to England he was introduced to parliament as one of the representatives of Rye, and took his seat under the avowed patronage of the minister, Mr Pitt. His first speech was delivered on the 27th February 1792, and manifested considerable ability. His next public appearance was as an opponent of the abolition of the slave trade. On the 2d of April 1792, Mr Wilberforce moved, in a committee of the whole house, "that the trade carried on by British subjects for the purpose of obtaining slaves on the coast of Africa, ought to be abolished." Mr Dundas proposed to insert the word "gradually," before the word "abolished;" but Mr Jenkinson moved "that the chairman should leave the chair." The amendment was, however, rejected by a large majority, and Mr Dundas's more adroit proposition agreed to.

Mr Jenkinson's next appearance was in a more prominent and less questionable position. The King of France had been deposed, and the British ambassador, Lord Gower, recalled. On the 15th of December 1792, Mr Fox moved an address to the king, praying that a minister might be sent to Paris to treat with the provisional government of France, touching such points as might be in discussion between his majesty and his allies, and the French nation. In the temporary absence of Mr Pitt, who had vacated his seat by accepting the wardenship of the Cinque Ports, Mr Jenkinson replied to Mr Fox, in a speech which was warmly complimented by Burke. The motion was negatived without a division. In April 1793, Mr Jenkinson was appointed one of the commissioners of the India Board; and on the 6th of May he stood forward in opposition to Mr

Grey's memorable motion on the subject of parliamentary reform. On the 6th March 1794, he opposed Mr Grey's motion for an address to the king, expressive of the concern of the House that his majesty should have formed an alliance with powers whose apparent aim was to regulate the affairs of a country with which they had no right to interfere. On the 10th of April, he undertook a more difficult task, namely, to justify the measures of the ministry, and to palliate the failure of the army commanded by the Duke of York at Dunkirk. On the 30th May 1794, he made one of his best efforts, in opposition to Mr Fox's motion, for putting an end to the war with France. This was perhaps the most active period of his life.

On the 25th March 1795, he married the third daughter of the Earl of Bristol and Bishop of Derry. At the opening of the session of 1796, the address was seconded by Mr Stewart, afterwards Lord Castlereagh, in the first speech delivered by him in the House of Commons. He was answered by Mr Sheridan, who strongly censured ministers, at the same time advising them to declare themselves willing to treat with the French Republic. Mr Jenkinson replied to Mr Sheridan, repeating his former arguments in justification of the government measures. On Mr Grey's motion in the House of Commons (10th March 1796) for an inquiry into the state of the nation, Mr Jenkinson descanted on the effect of the war upon our commerce, contending that, notwithstanding its pressure, the situation of Great Britain, in a commercial point of view, was more prosperous than at any preceding period. On the 28th of May 1796, he participated in the honours of his family, exchanging its surname for his father's second title of Lord Hawkesbury. On the temporary retirement of Mr Pitt from power early in 1801, a new ministry was formed, with Mr Addington at its head; and Lord Hawkesbury, who was appointed to the office of secretary of state for the foreign department, took a prominent part in the debates which ensued. The great business of the succeeding summer and autumn consisted in the adjustment of preliminaries of peace with France. In October Lord Hawkesbury remonstrated against the occupation of Switzerland by the French under Ney, in order to enforce the reception of a new constitution for that country, prepared by the First Consul in his own cabinet.

At this period, the management of the House of Commons had, in a great measure, devolved on Lord Hawkesbury, who, of course, spoke on every topic involving the character of the administration, as well as on the political questions which were brought under the consideration of the House of Commons. At the opening of the next session of parliament he was called to the House of Lords; but the only measure of importance which in that session he brought forward in the new situation in the legislature where he had been placed to defend the measures of ministers, was the Volunteer Consolidation Bill. About the same time he addressed a circular to the ministers of foreign courts resident in London, disclaiming indignantly the charge that his majesty's government had been a party to plans of assassination, and describing the recent seizure and execution of the Duke d'Enghien as "a sanguinary deed, perpetrated by the direct order of the First Consul, in violation of the rights of nations, and in contempt of the most simple laws of humanity and honour."

On the 12th of May, the administration was dissolved by the resignation of Mr Addington; Mr Pitt returned to the head of the ministry, and Lord Hawkesbury received the seals of the home department. The renewal of the war being now inevitable, the first effort of the new government was to place the military establishments of the country on a more enlarged and efficient footing; and, with this view, Lord Hawkesbury exerted himself in the House of Lords in support of the Additional Force Bill. At a later

Livery. period of the session, Mr Wilberforce renewed his attempts to put an end to the slave trade, and a bill for that purpose passed the House of Commons; but on its transmission to the House of Peers, it was postponed, on the motion of Lord Hawkesbury, for more mature investigation in the ensuing session. On the 10th of May 1805, Lord Grenville moved the order of the day for taking into consideration the petitions of the Roman Catholics of Ireland. This motion Lord Hawkesbury also opposed. The death of Mr Pitt afforded Lord Hawkesbury an opportunity of placing himself at the head of the cabinet; but being well acquainted with the relative position and strength of parties, his ambition yielded to his good sense, and he declined the flattering offer. He was, however, the political heir of Mr Pitt in all except his talents. Towards the close of 1808, Lord Hawkesbury was, by the death of his father, placed at the head of his family, as second Earl of Liverpool.

Under the administration of Percival, Lord Liverpool became secretary of state for the war department, and after the assassination of the premier, he was placed at the head of the government. (See BRITAIN.) Lord Liverpool died 4th of December 1828.

LIVERY. When the Greeks used the proverbial saying—*μάστιγον ἀνὴρ*, "the dress shows the man"—they applied the pithy "saw" as much to the social condition as to the moral character of the individual. The "livery" has, accordingly, ever been taken to mark rather than distinguish the menial or the mercenary. The latter, however, resists the term, and claims for his dress the name of "uniform." When Cœnomaus clothed his circus troops in green or blue costumes, he did not, as many have asserted, introduce the fashion of liveries; he simply decked his mimic warriors in fancy dresses. The custom of livery is really derived from the term *liberata* or *liberatio*, a term applied to the delivery or distribution (made by the kings of the Merovingian and Carolingian races) of particular sets of clothes to the servants throughout the palace, and at the sovereign's expense. In common phrase, this was called a *livrée*, and it was ordinarily performed in the plenary courts of France.

A term of similar signification was given to the distribution made by the early German emperors, and which consisted of uniform dresses and wages delivered into the hands of the servants of the imperial household.

In the days of chivalry, livery, in the proper sense of the word, often covered noble backs, without bringing disgrace thereon. The duke's son, as page to a prince, wore the prince's livery. The earl's second son, serving a duke, donned his master's coat and colours. The knight's second son was in a similar condition as an earl's servant. The esquire's son joyfully wore the livery of the knight whom he served; and the gentleman's son performed, in a similar dress, the duty of servant to the esquire. More than this, the younger brother of a nobleman has been known to serve his elder brother, and to wear, with all humility, the older kinsman's coat and badge.

This badge was formerly the indispensable accompaniment to the coat. "Livery and badge" are as old as the time of Edward IV. The badge was a cloth or silver circle, borne on the left arm, and carrying the crest of the wearer's master. It is still retained by a few noble families; and, as a fashion, it yet lingers on the coat sleeves of corporation watermen and the fraternity of firemen. At first, however, the mode was so general—the habit itself being blue, and the badge affixed to it—that the proverb arose, applicable to things or persons lacking ordinary appendages—"Like a blue coat without a badge."

The silver badge was probably peculiar to England, as it appears, in the time of Elizabeth at least, to have excited the astonishment of most foreign travellers. Laced cloaks

were delivered to servants, in the reign of James I., according to the assertion of the gossiping Fynes Moryson, who further informs us that, sixty or seventy years before he was writing, A.D. 1617, coaches were very rare; but that at the date just mentioned, there was scarcely an elder brother who was without one; and that these cumbersome vehicles, with their liveried coachmen, continually "stopped the way." We get at an additional social trait connected with the wearers of livery, in the remark, that "Londoners say woe to him that taketh a servant from St Paul's church"—in one of the aisles of which they walked about, waiting to be hired.

During a very considerable period, livery was worn by other common men besides salaried menials. The men alluded to were the "retainers" of noblemen. These retainers served for a year, and wore their hirer's livery. Their service was that of the strong hand, which was ever ready to be raised, and prompt to descend, in their masters' quarrels. They wore a full suit, and were a formidable body; so formidable that, without license, no noble could at last retain such followers. The law ordained, with some singularity, that a master was permitted to give livery only to his own household servants, officers, and counsel learned in the law! The act was evaded, and then the penalty of imprisonment which it awarded was increased by a fine of L.5 per month for every retainer kept without license.

Henry VII. was, of all English sovereigns, the one who looked most sharply after the means of increasing his revenues; and, on one occasion, he applied this matter of unlicensed liveried retainers to that particular object. The king had been the guest of his old and faithful servant, the Earl of Oxford, at Henningham. Hospitality to a monarch was a heavy charge to the moderately wealthy earl, who, however, displayed a princely liberality. The king, at parting, told him that, much as his hospitality had been spoken of, his munificence exceeded report; and, as he spoke, Henry pointed to the long double row of liveried servants who lined each side of the way by which he passed. A man who could keep so many menial servants must be of princely means indeed. The earl, however, hastened to reply, that, in that sense, he was not their master. They were, he said, simply retainers of his who attended there to do him service, and partly out of curiosity "to see his grace." "Now, by my faith!" exclaimed Henry, "I may thank you, my lord, for your good cheer; but I may not endure to have my laws broken in my sight. My attorney must speak with you." The threatened colloquy was a costly one, for the poor earl was mulcted in the enormous sum, for the period, of L.10,000, only for putting his livery on a few scores of backs, contrary to the statute of Henry's first parliament.

It has been observed of Queen Mary, that she granted more licenses by half, for permission to maintain liveried retainers, in five years, than her sister Elizabeth did in thirteen. In the briefer time, Mary granted thirty-nine licenses, while in the more extended period, Elizabeth signed only fifteen. Mary, too, sometimes gave permission to one man to maintain two hundred retainers; but Elizabeth never consented to allow more than one hundred to the same individual. Mary's bishop, Gardiner, had not less than two hundred of these liveried soldiers, rather than servants, while Elizabeth's archbishop, Parker, was permitted to raise only forty. The license to the latter, which is printed in the volume of the correspondence of the prelate, edited for the Parker Society by Mr Bruce and the Rev. T. T. Brown, is addressed by Elizabeth "To all men," to whom it says, "Know ye this, of our special grace, certain knowledge, and mere motion, and by the advice of our council, we have given and granted full authority, power, and license, unto the most reverend Father in God, Matthew, Archbishop of Canterbury, full authority

Livery.

Livery. that he during his life; may lawfully, and without question, loss, damage, forfeiture, or other penalty, retain and keep in his service, from time to time, by way of retainers, over and besides all such persons as daily attend upon him in his household, and to whom he giveth meat, drink, livery, fee, or wages, and also over and besides all such persons as shall be under him in any office, of any stewardship, under-stewardship, bailiffick, keeper of park-houses, warrens, or other games of venerie, pheasants, partridges, and other fowls of what kind soever, &c., the number of forty persons, gentlemen, or yeomen, though they be tenants to us, or resident within our honours, &c.; to give, at his pleasure, his livery, badge, or cognisance, &c., to do unto him their service, &c.; the said persons to be reputed, taken, and accepted, by virtue of this our grant and license, to all instructions, constructions, and intents, as of the daily attendants of the said archbishop in his household. Provided that this our grant shall not extend unto him to take or retain into his service any of our servants being named in our cheque roll, nor any other being sworn or retained to serve us as our said servant. And furthermore, we have pardoned and released to the archbishop all and every trespass, or acts of retainer heretofore had, or any contempt, violation, or forfeiture, &c., perpetrated or done since the first of January last past, contrary to any act of retainers, &c. In witness, &c., the 16th day of May, in the 5th year of our reign."

Licenses and retainers were alike abolished in the reign of Charles II. Since that period, livery has only been worn by the lower class of male household servants. While a servant wears livery, he is addressed by his Christian name, but when he is promoted from the servants' hall to the steward's room company, he drops his baptismal, and is thenceforward distinguished by his surname. The coachman is the recognised chief of the liveried corps; and at meals he presides at the head of the table, by right of his office, in establishments where the unliveried gentlemen take their repasts at a separate table. Many of the appendages of livery may be traced to fashions in dress once patronized by nobles. The long waistcoat of the groom is the old undercoat of the esquire, and the three-cornered hat of the coachman once figured at sovereign courts on aristocratic brows. It was driven out of fashion by being stigmatized as "an Egham, Staines, and Windsor," from the triangular direction-post to these places which it was said to resemble. There is one instance of waiters at a tavern wearing livery. It is noticed by Walpole, who describes the "drawers" at the King's Arms as being dressed in brown frocks with blue aprons. This seemed too poor for Sir Ralph Gore, who gave them laced clothes. In France, where the fashion of liveries was occasionally of extravagant splendour, and wealthy men delighted in feeling helpless, and maintaining a crowd of Frontins and Germains to minister to them, the fashion and the word so betokened a menial, that liveries were abolished by the Constituent National Assembly, as incompatible with a republican system founded on the imaginary tripod of liberty, equality, and fraternity.

In France, however, the laced brotherhood may boast of having had Rousseau for a member. It will be remembered that, when waiting at table, he corrected his master's faults in grammar. In England, Dodsley, the once well-known author and publisher in Pall Mall, commenced life in the same menial condition. He was footman in the service of the honourable Mrs Lowther when he published his first poetical work, "The Muse in Livery," with a long list of subscribers. The modest volume bore this epigraph:—

"You laugh, and think 'twould be a jest
To see a Muse in liv'ry drest;
But when I mount behind the coach,

And bear aloft a flaming torch,
Methinks on Pegasus I fly,
With fire poetic blazing through the sky."

Livery.

"What can be expected," he asks, "from the pen of a poor footman,—a character that expresseth want both of friends, fortune, and all the advantages of a liberal education, or a polite converse." The liveried poet speaks of his natural genius as "depressed by the sense of his low condition; a condition," he adds, "from which he never hopes to rise, but by the goodness of Providence influencing some generous mind to support an honest and a grateful heart." His description of a liveried servant's daily life is portrayed with some spirit; and the following lines will serve to show how he made of the dinner hour a time for improving himself:—

"This is the only pleasant hour
Which I have in the twenty-four;
For whilst I unregarded stand,
With ready salver in my hand,
And seem to understand no more
Than just what's call'd for out to pour;
I hear, and mark the courtly phrases,
And all the elegance that praises;
Disputes maintained without digression,
With ready wit and fine expression;
The laws of true politeness stated,
And what good breeding is, debated;
Where all unanimously exclude
The vain coquet, the formal prude,
The ceremonious and the rude;
The flattering, fawning, praising train;
The fluttering, empty, noisy, vain;
Detraction, mut, and what's profane."

Such was the footman who shared with Stephen Duck the patronage of the great; who wrote the *Cleone*, which gave immortality to the glittering beauty, Bellamy; who was the author of the once famous *Economy of Human Life*, which had the honour of being attributed to the pen of Chesterfield; and whose book-shop in Pall Mall was the resort of wits, statesmen, poets, philosophers, and fine gentlemen.

Dodsley lived and died in a century when footmen especially claimed and enjoyed a certain distinction. It was a century in which Lady Harriet Wentworth married Sturgeon, the favourite footman of her father, the Marquis of Rockingham. It was these favourite footmen who at the theatre occupied the seats retained in the boxes till the arrival of their mistresses. Their very crimes but took the guise of foibles; and Lady Mary Wortley Montague made a hero of a liveried Tarquin, named Arthur Gray. If they were esteemed living, they were sometimes honoured after death; and Walpole informs us how the old Duchess of Douglas, having lost her favourite footman in Paris, had his body embalmed, packed up in the front part of her own travelling carriage, and brought to England, under her personal escort, for interment! The dignity of the office was signified on one occasion by the state coachman of George II., who left a fortune to a son in plush,—a portion of which he was to forfeit, in the event of his condescending to marry a maid of honour. So puffed up, indeed, was this class of retainers by their fancied importance, that when the Rev. Mr Townley's farce of *High Life Below Stairs* was first represented, the exposure of these mock pretensions of the brotherhood was met, in the London and Edinburgh theatres, by such serious riots on the part of the "gentlemen's gentlemen," as to cause the abolition of their free admission to the gallery, and to bring upon them a hurricane of ridicule, beneath which their dignity and pretensions were wrecked for ever. The latter did not even revive when the late eccentric Lord Harrington "cut out" those shapeless livery coats for his own men, which, for a time, elicited more surprise than admiration on the part of

Livius.

all beholders. Many instances might be cited from the histories of the South Sea and Mississippi schemes, of footmen speculating into large fortunes, and occasionally, through forgetfulness, getting up behind, instead of into, the carriages which fortune had enabled them to set up. But the most striking example of the two extremes is in the case of "Baron Ward," who commenced life as a livery servant, and who ended his public career as prime minister of the late Duke of Parma.

The poets have made ample use of the menial word, and with poetic power have conferred on it a real dignity of application. One speaks of wearing the "virtuous livery" of his mistress; another puts "April's livery" on spring; Milton makes of twilight the "sober livery" of evening; and of a tropical complexion the "shadowed livery of the burnished sun." Hood has, with his usual happy facetiousness, described the livery of earth as "grass-green turned up with brown;" and a French moralist places two parties on the same level by stating that "les ambitieux et les laquais portent indifféremment toutes les livrées."

The word "livery" is further applied to the 91 companies of the city of London. The members of these companies originally wore habiliments in form and colour resembling those of the lord mayor and sheriffs. The wardens of companies were accustomed annually to deliver to the Lord Mayor certain sums, twenty shillings of which were given to individuals who petitioned for the money, to enable them to procure sufficient cloth for a suit. When the companies thus wore their liveries, the splendour of the civic train was the pride of all good citizens.

There remains only to notice the word "livery" as a legal term. In this sense it implies to give and take possession. It also signifies a release from wardship; and, before written deeds were common, it was applied to that form of conveyance of copyhold estates, when the seller delivered a rod or wand to the lord, which the latter placed in the hands of the purchaser, in the presence of tenants, who were called upon to witness this act of "livery."

Finally, and to return to the earlier division of our subject, the reader is referred to Fielding's *Joseph Andrews* for a brief sketch of what the liveried footman of the last century was. He aped all the fashionable vices of the day; wore his hair in papers in the morning, and curled in the afternoon; criticised new operas, was riotous at the play, rather rollicking at church, and gave accommodation money to the steward for paying his wages half a year before they were usually payable, which was "perhaps half a year after they were due." It was a period when society was generally corrupted, and when masters were as proud of their vices as their servants were of their liveries.

(J. D.—N.)

LIVIVS, TITUS, the most celebrated of the Roman historians, was descended from an illustrious family which had given several consuls to Rome. Only a few particulars of his life have been transmitted to us. He was born at Patavium, now *Padua*, in the N. of Italy, B.C. 59, the year before Cicero was driven into banishment; and died at the advanced age of seventy-six, A. D. 17, the same year as Ovid. He resided during the greater part of his life at Rome; and, if we may credit a statement of Suetonius (*in Claud.* 41), became the instructor of the Emperor Claudius. His history was written partly at Rome and partly at Naples, and it is said that his reputation was so widely diffused, that a native of Gades, now *Cadiz*, in Spain, actually visited Rome for no other purpose than to have the pleasure of forming an acquaintance with the historian. (*Plin. Ep.* ii. 3.) From some inscriptions found at Padua (*in* 1413), it has been asserted that Livy was twice married, and had two sons and four daughters; but this must rest merely on conjecture, as there were no doubt many of the same name in Padua. Seneca (*Proem. v. Controv.*), indeed,

states that one of his daughters was married to L. Magius, the rhetorician.

Livius.

Besides his history, we are acquainted with the titles of three other works of which he was the author; but not a fragment of them has been preserved. These were,—*Epistola ad Filium scripta*, mentioned by Quintilian (*i.* 10); *Dialogi*, which Seneca (*Epist. c.*) hesitates whether he ought to class amongst historical or philosophical works; and *Libri ex professo Philosophiam continentes*. The loss, however, of these works is less a subject of regret than that of the greater part of his *Roman History*, or, as he himself modestly entitles it, *Annals of the Roman People*. This work extends from the building of the city to the year 744 (B.C. 9), when Drusus was carrying on war in Germany, and in which he died. Livy undertook this work probably at the suggestion of Augustus, when he was already far advanced in years. It consisted of 142 books, of which only thirty-five remain; and some of these (*lib. xli. xliii. xlv. xlv.*) are in a very imperfect state. The first ten contain the history of Rome from its foundation to B.C. 294; the others (*xxi. xlv.*) from B.C. 219 to B.C. 167, or from the beginning of the second Punic war to the end of the wars with Perseus and Gentius. Of the remaining books we possess only considerable fragments, with short epitomes, which have been supposed, though without any sufficient reason, to have been composed by the writer Florus. The whole were not discovered at one time, but were supplied partly from MS. belonging to the cathedral church of St Martin at Mayence, partly from one found in the convent of Lorsch, near Worms, and partly from a palimpsest in the Vatican, of which Niebuhr published a full copy at Berlin in 1820. No MS. has yet been discovered containing all the books now extant. There is, indeed, no loss that has befallen us in Roman literature at all to be compared to that which has left this history imperfect.

Livy follows a chronological arrangement in his history, and, like Dionysius of Harlicarnassus, has adopted the Cætonian era for his basis. He therefore supposed the city of Rome to have been founded B.C. 751, whereas Varro placed it two years earlier, B.C. 753. The sources from which he derived his information, more particularly for the earlier parts of his history, seem less worthy of belief, though he probably had recourse to the best within his reach. All the more ancient historical records had no doubt disappeared, and he could therefore only be acquainted with their statements through the medium of later annalists. For this early period he had recourse to the works of no Greek historian, unless we include amongst them that of L. Cincius Alimentus, who, though a Roman, wrote in the Greek language. This author served in the second Punic war, and he is called by Livy (*vii.* 3) a most diligent investigator of ancient monuments. In the early part of the war he fell into the hands of Hannibal, and from him he received an account of his passage through Gaul and across the Alps, which he incorporated in his history. To the works of this writer Livy acknowledges himself much indebted. As to the sources from which he drew his materials for the second decade (*xi.–xx.*), which is lost, all that can be said is only matter of conjecture; but we know that Polybius was the principal writer whom he consulted, and that he followed that writer generally both in the arrangement of his materials and in the development of the story. It is not a sufficient answer to this that Livy seldom alludes to Polybius as his authority, since he does not think it necessary to cite the writer upon whom he depends for his information, unless on occasions where there is a difference of opinion. There is no doubt, that wherever he has adopted the statements of Polybius, we may place perfect confidence in the account; and yet, where they differ, we must not condemn Livy, who evidently consulted Roman authorities of undoubted credi-

Livius. lity, and who may, upon due examination, have come to the conclusion that Polybius was mistaken. The difference in the accounts given by the two historians of Hannibal's passage across the Alps is an example of this, though the balance of probability is greatly in favour of that of Polybius.

Livy has been accused of a wilful perversion of the truth, of an undue partiality for his own country, and a desire to recommend himself to the favour of the nobility, by flattering their pride by the manner in which he records the deeds of their ancestors. But if he represents the characters of his countrymen in a different light from other writers, might he not suppose himself better able to appreciate their conduct? and if his love of country led him to conceal whatever might be prejudicial to them in the eyes of posterity, it was a fault for which he may be forgiven, though it certainly must be allowed to detract considerably from the value of his work. He has been accused also of superstition, because he has reported faithfully all the prodigies and omens in which those early ages abounded, and which seemed to have formed the principal part of their religion; but he has several times observed, that he narrates those wonderful events because he found them in the ancient annalists whom he consulted, without meaning to vouch for their accuracy. Livy was evidently gifted by nature with a brilliant talent for narration, and for seizing the characteristic features of humanity. He was a poet, though without the power or perhaps the love of versifying. His rhetorical powers, too, were of the highest order; and, in the palmy state of the republic, he would have ranked among the first orators of his age. The periods of Livy are full and well rounded, in imitation of the style of Cicero; and indeed the age in which he lived would have tolerated no other mode of writing. It is strange that there should be any difficulty in discovering the political sentiments of the historian; but he felt that he was writing under the eye of a despot, however amiable, and he thought himself obliged to suppress many sentiments to which he would, in other circumstances, have given utterance. He was fully sensible of the degeneracy of his own days, and was glad to forget it by reviving the recollection of all that was glorious and noble in the past. He might also imagine that he could excite in the breasts of his countrymen a desire to emulate the heroic deeds of their ancestors, and might thus be the means of restoring the constitution of his country to its ancient form and strength. It is said that Augustus accused him of being too favourable to the party of Pompey (Tacit. *Ann.* iv. 34); and we may therefore conclude that he was in his heart a partisan of the republic. It has been much disputed what Asinius Pollio (*Quintil.* viii. 1) meant by the accusation he brought against Livy of Patavinity (*Patavinatas*); but it seems the most likely conjecture that it was some provincialism in the language and style, perceptible to the refined ear of a Roman critic, though we can no longer discern it.

Livy's history was first printed at Rome, about the year 1469, by Sweynheym and Pannartz, in folio. Of this rare edition Lord Spencer is in possession of a fine copy; but the most exquisite one is that printed on vellum, which formerly belonged to the Imperial Library at Vienna, but was afterwards acquired by a private collector in England. Among the subsequent editions of the history may be mentioned that of Gronovius, who first placed the text upon a satisfactory basis by a collation of many MSS., of which the best edition is printed by Elzevir, 3 vols. 8vo, 1679; that of Leclerc, 10 vols. 8vo, Amsterdam, 1710, containing the supplements of Freinsheimius entire; that of Crevier, 6 vols. 4to, Paris, 1735. The standard edition is considered to be by Drakenborch, published at Leyden, in 7 vols. 4to, 1738-46. Later editions, by Ruperti, Göttingen, 1807; and of Bekker and Raschig,

Leipsic, 1829, are of less value. There is a new edition by Alchefschi, Berlin, 8vo, 1841, brought down to the end of the first decade; but perhaps Drakenborch, with the *Commentaries* of Lachmann, supplies every assistance necessary for the scholar. (See Schweiger's *Handbuch der Classischen Bibliographie*, 8vo, Leipsic, 1839.) There are the following English translations:—Philon Holland, folio, London, 1600-1659; Baker's, in many editions; and one published by John Hayes (London, 1744-45, 6 vols. 8vo), said to be executed by several hands; also one in Bohn's Classical Library, 1850.

LIVIVS, Andronicus, a comic poet who flourished at Rome about 240 years before the Christian era. He was the first who turned the personal satires and Fescennine verses, so long the admiration of the Romans, into the form of a proper dialogue and regular play. Though the character of a player, so valued and applauded in Greece, was reckoned vile and despicable amongst the Romans, Andronicus acted a part in his dramatical compositions. Andronicus was the freedman of M. Livius Salinator, whose children he educated. His poetry had grown obsolete in the age of Cicero, whose nicety and judgment would not even recommend the reading of it. Horace mentions his dramas as popular in schools; but Suetonius says they were mere translations from the Greek. His *Hymns* are said to have been sung to propitiate the gods. A Latin *Odyssey* is attributed to him; but of this, as well as of his plays, tradition has only preserved the name.

LIVONIA, or **LIVLAND**, a maritime government of Russia, on the Baltic, bounded N. by Esthonia, W. by the Gulf of Riga (which contains the island of Oesel, belonging to this government), S. by Courland and Vitepsk, and E. by Pskov and the Peipus Lake, between N. Lat. 56. 30. and 59. 6, and E. Long. 23. 10. and 27. 35. It is 170 miles in length from N. to S., by 110 miles in breadth, and contains an area of 18,146 square miles, with a population, in 1851, of 821,457 persons. The general surface of the country is flat, and in some places marshy. Undulations, however, occur here and there; and near Venden an elevation called the Mesenberg rises to the height of 1200 feet. Lakes cover a large part of the surface, and are mostly extensive sheets of water. The largest is the Peipus See, which separates Livland from the government of St Petersburg, and is connected by a narrow channel with Lake Pskov to the S. It is 50 miles long from N. to S., by 27 broad, contains several islands, the largest of which is Porka, and is well stocked with fish. The shores of the lake are low and marshy; and its waters, though sufficiently deep for small craft, are subject to frequent squalls. Lake Vitzerve, occupying a central position in the government, is next in size to the Peipus, and communicates with it by means of the Embach. The chief river is the Dwina, which for some miles separates this government from Courland, and afterwards flows through Livland to its mouth near Riga. The other important streams are the Aa, Salis, and Pernau, all of which take their rise in the government, and fall into the Gulf of Riga. Livonia suffers from extreme and protracted cold in winter, and great heat in summer. The former, however, is advantageous for the conveyance of goods from the interior to the seaports by means of sledges, enabling vessels to start from Riga and elsewhere immediately on the return of spring. Agriculture and cattle-rearing form the great occupations of the Livonians. The soil is for the most part sandy, with here and there districts of clay and loam. Grain and potatoes form the principal agricultural products, while from the extensive forests the inhabitants are supplied with abundance of fuel and excellent timber. Among its other productions, the chief are flax, hemp, linseed, and hops. Live stock receives a considerable amount of attention, especially from the large proprietors, who vie with each other in improving their breeds of cattle and horses.

Livius
||
Livonia.

Livonia. The following table shows the area of the cultivated and waste lands of Livland, according to the government commission of 1849:—

	Square Miles.
Arable land.....	1,740
Meadow.....	2,281
Private domains.....	2,251
Wood.....	4,026
Waste.....	7,847
Total.....	18,146

In the same year 449,484 qrs. of grain seed produced 2,033,904 qrs. of grain; and 131,605 qrs. of potato seed produced 244,509 qrs. of potatoes. Of live stock belonging to this government in 1849, there were 120,654 horses, 350,999 cattle, 315,195 sheep, and 148,945 swine.

Fishing and seal-taking are the occupations of the inhabitants of the sea and lake coasts. Manufacture may be said to be deficient, and in a rude state, being mostly confined to the home-spinning of wool and flax. Large quantities of grain and timber are yearly sent from this government by Riga to Western Europe, in return for coal, iron, salt, wine, &c. Game is plentiful, from the extent of the waste land. Bears, wolves, and foxes exist,—the latter in considerable numbers; while beavers, lynxes, squirrels, and martins, are hunted for their valuable furs. Aquatic birds frequent the lakes and marshes in great flocks.

Livonia, for administrative purposes, is divided into five circles, named after their respective chief towns, viz., Arensburg, Dorpat, Pernau, Riga, and Venden. The revenue of the government in 1849 amounted to L.586,444.

The population is a mixed race, composed of Livonians, Esthonians, Germans, Swedes, Russians, and Jews. The first, who occupy the southern portion of the country, are remarkable for their want of enterprise and great love of home. They are, however, of good disposition, and exhibit great mechanical ingenuity. Most of the trade is in the hands of the Russians and Germans, especially the former. Lutheranism is the dominant religion, while the Greek Catholics consist only of the few Russian residents. Riga, the capital, had in 1849 a population of 57,906 persons.

The history of Livland commences in 1158, when it was visited by some Bremen merchants, who established a trading post at the mouth of the Dwina, where Riga now stands. They found the inhabitants in an uncivilized and heathen condition; and in order to convert them to Christianity, instituted an order of religious knighthood, called the "Schwertbrüder," or Brothers of the Sword. These spread the gospel by force of arms, and claimed the Livonians as subjects as well as converts. In 1237 the "Schwertbrüder" united themselves with the order of German knights; retaining, however, their own grand-master as head of the band. From that year till the sixteenth century, Livland and Esthonia were under their control. But the Lutheran Reformation had then spread into the adjoining states, and both Livonia and Esthonia ultimately declared for the new faith. But at the time when Protestantism was struggling with the old religion, the Russians took advantage of the civil commotions that arose, and frequently invaded the land, receiving but slight resistance from the "Schwertbrüder," who had become too weak to protect their own territories. Gotthard Kettler, last grand-master of the order, abdicated his power over the province in favour of the King of Poland, and afterwards retired to Courland, which he received as a dukedom in return. But Poland did not enjoy her acquisition in peace, for the Swedes and Russians, as possessors of Esthonia, laid claim to Livonia, and soon appealed to arms in support of their demands. They were successful, and by the treaty signed at Oliva in 1660, Poland surrendered her possession to Sweden. In the next century, however, after Peter the

Great had defeated Charles XII. of Sweden, Livonia was finally given over to Russia, according to the treaty of Neustadt, in 1721.

LIVORNO. See LEGHORN.

LIXURI, a seaport town of the Ionian island Cephalonia, is situate on the W. shore of a large creek that runs inland from S. to N. It is the seat of a Greek bishop, and carries on a considerable trade. Pop. 6000.

LIZARD POINT, a bold headland on the S.W. coast of England, county of Cornwall, on the English Channel, N. Lat. 49. 57. 40., W. Long. 5. 11. 5. This is the most southern land in Britain, and generally the first sighted by vessels entering the Channel. It is surmounted by two fixed lights, the one 221 feet, and the other 225 feet above sea level. The rock is formed of hornblende and mica slate, and constitutes a rugged and precipitous coast. About a mile to the W. of the point is Old Lizard Head, with the dangerous rocks to seaward known under the name of the Stags. The *Ocrinum* of Ptolemy was either this head or Lizard Point.

LLANDAFF (*the Church on the Taff*), an ancient city, and seat of a bishopric of Wales, Glamorganshire, is situate on the right bank of the river Taff, about 2 miles N.W. from Cardiff. A church is said to have existed here from the period of the introduction of Christianity into Britain; but it does not appear that a bishopric was constituted until about the middle of the sixth century. The city is now only an insignificant village, claiming notice solely on account of its cathedral. This edifice, standing apart from the village in a hollow by the river-side, was begun by Bishop Urban in 1120, but not completed before the end of the thirteenth century. The prevailing style of the edifice is Gothic, but this is blended with much of early Norman, and some portions exhibit the architecture of later periods. The W. front is an admirable specimen of the early pointed style; and at the N.W. angle is a lofty square tower of the Tudor age, profusely enriched with sculpture. During the last few years extensive restorations have been made under the direction of Dean Conybeare. In the N. aisle are a number of curious monuments, with effigies of mailed warriors and mitred bishops; but the principal of these were much defaced or destroyed by Owen Glyndwr. Pop. of parish (1851) 1821.

LLANDEILO-FAWR, a market-town of S. Wales, Carmarthenshire, on the Towy, 14 miles E.N.E. from Carmarthen. The town is small and ill-built, and, excepting the new church, contains no important buildings. Near the town, in 1282, Llewelyn was defeated by the forces of Edward I., under the Earl of Gloucester and Sir Edmund Mortimer. In the vicinity is Dynevor Castle, built near the ruins of an ancient fortress of the same name, for a long period the residence of the princes of S. Wales. Adjoining the town is a valuable chalybeate spring. Several productive coal and iron mines in this district are connected by a railway with the port of Llanelly. Pop. of parish (1851) 5758.

LLANDOVERY (*Llan-ym-Ddyfri*, "Church among the Waters"), a municipal borough and market-town of S. Wales, in Carmarthenshire, about 23 miles E.N.E. from Carmarthen, in the valley of the Towy, near the confluence of that river with the Brân. The streets are irregular, and the only buildings worthy of note are, the parish church, several dissenting chapels, some schools, and the Welsh Educational Institution, founded and liberally endowed, in 1848, by Thomas Phillips, Esq. Near the town, on an insulated rock, is the keep of an old castle, built at a very early date, and dismantled by Cromwell. The vestiges of Roman roads, and the discovery of Roman coins, seem to indicate that Llandovery was once a Roman station. Market-days, Wednesday and Saturday. Pop. (1851) 1927.

LLANELLY, a municipal and parliamentary borough and market-town of S. Wales, county of Carmarthen, on

Livorno
||
Llanelly.

Llanfyllin a rising ground near the Burry Creek, about 15 miles S.E. from Carmarthen, and on the railway between that town and Swansea. It is irregularly built, and has an antique parish church surmounted by two steeples, the one terminating in a spire, and the other in a parapet. The excellent harbour and docks of this town, its communication by railway with the rich coal-fields of the N.E., and its position on the verge of the mineral basin of S. Wales, have combined to raise it to its present prosperity, and promise soon to render it one of the most important ports of the principality. In addition to the iron and lead ore furnished by the neighbourhood, copper ore, imported from Cornwall, is smelted, and the manufactured metal is sent to Liverpool and other English ports. Great quantities of coal are also exported to France, Spain, and the Mediterranean. In 1855 there were exported from Llanelli to foreign countries, of British copper, 522 tons 14 cwt.; of lead and lead ore, 1815 tons; of coals, cinders, and culm, 24,118 tons. On the 31st December there were registered as belonging to the port, 40 sailing vessels of and under 50 tons, with a tonnage of 1103; and 41 above 50 tons, with a tonnage of 3915; steam-vessels under 50 tons 2, tonnage 36. During 1855 there entered the port of Llanelli, of British vessels, 1891, tonnage 118,383; of foreign vessels, 163, tonnage 10,555. There cleared out, of British vessels, 3152, tonnage 217,813; of foreign vessels, 165, tonnage 10,440. The inhabitants are chiefly employed in the lead and copper works, the iron foundries, and the mines. Market-days are Thursday and Saturday. The parliamentary borough is contributory to the Carmarthen district. Pop. of borough (1851) 8710.

LLANFYLLIN, a small market-town and parliamentary borough of Wales, in Montgomeryshire, on the River Cain, an affluent of the Vyrwy, 17 miles N.N.W. from Montgomery. The two chief edifices, both built of brick, are the town-hall and the church, the latter erected in the Venetian style, and possessing a fine peal of bells. The town is celebrated for its ale. Some Roman coins have been found here. The market-day is Thursday. There are six annual fairs, at which the celebrated "merlins," or Welsh ponies, are sold in great numbers. The borough is contributory to Montgomery. Pop. (1851) 1116.

LLANGFNI, a parliamentary borough and market-town of Wales, county of Anglesea, is situate in a fertile vale on the River Cefni, about 15 miles E.S.E. from Holyhead. At its annual fairs great numbers of cattle are sold for the English market. In the vicinity there are vestiges of a paved road supposed to be Roman. The borough is contributory to Beaumaris. Pop. (1851) 1362.

LLANGOLLEN, a town of Wales, in Denbighshire, is situate in a narrow valley watered by the Dee, on the high road between Holyhead and London, distant 184 miles from the capital. The town, mean and irregular in appearance, with streets narrow and ill-paved, is a favourite resort of tourists. Spanning the River Dee is a bridge of four narrow angular arches, built by Dr Trevor, Bishop of St Asaph, about the middle of the fourteenth century, and long remembered among the "seven wonders of Wales." On the summit of a high conical hill, about a mile from the town, stand the imposing ruins of *Castell Dinas Brân* or Crow Castle, a fortress of very ancient date. The remains of *Valle Crucis Abbey*, or *Llan Egwast*, founded about 1200, is 2 miles N.W. of Llangollen. In a meadow near the abbey stands *Elise's Pillar*, a round column covered with an ancient inscription of the seventh century, now illegible. The Ellesmere Canal is carried across the valley of Llangollen, and crosses the Dee about 4 miles from the town, by the Pont-y-Cyssyllte aqueduct of 19 arches and 126 feet in height. Its length is 1009 feet. The population are chiefly employed in manufacturing woollen and flannel stuffs, and in quarrying stone and lime. Llangollen is a

polling-place for the county, and has a market every Saturday. Pop. of parish (1851) 5260.

LLANIDLOES, a municipal and parliamentary borough and market-town of Wales, Montgomeryshire, is situate on the Severn, near its confluence with the Clywedog, 19 miles W.S.W. from Montgomery. The town consists partly of hovels built of wood and mud, and partly of recently erected houses, which are gradually replacing the old. The chief buildings are,—the new market-house, in the centre of the town, and the ancient church of St Idloes, remarkable for the ornamented pillars and the delicately carved oaken roof, which are said to have been transferred from Cwm Hir Abbey, in Radnorshire. There are extensive sheep walks on the surrounding hills, which supply the materials for the flannel manufacture, the chief source of the town's prosperity. The quarries of coarse slate, and the lead and copper mines on the slopes of Plinlimmon, employ a part of the population. A market for wool and corn is held on Saturday. The borough is contributory to the Montgomery district. Pop. of borough (1851) 3045.

LLANRWST, a market-town of N. Wales, partly in Carnarvonshire, but principally in Denbighshire, situate on both banks of the Conway, in a valley surrounded by well-wooded hills, 17 miles W.S.W. of Denbigh. The old church, an erection of the fifteenth century, and built on the site of a much older one, contains some interesting monuments. Inigo Jones furnished the design of the Gwydir chapel, in the south transept, which, among other curious relics, has the large stone coffin of Llewelyn the Great, son-in-law of King John. The bridge across the Conway was built in 1636, from designs by the same eminent architect. At one period, Llanrwst was celebrated for the manufacture of Welsh harps; there was also, somewhat later, a good deal of woollen-yarn spinning and stocking-knitting carried on, but neither of these is now of much importance. Coals and lime are brought up the river to Trefriw, and slate and iron sent in return. The markets are on Tuesday and Saturday. Llanrwst is celebrated for the excellence of its salmon-fishing. Pop. of parish 3984.

LLANTRISAINT ("the Church of Three Saints"), is an ancient parliamentary borough and market-town in Glamorganshire, Wales, 8 miles N.W. of Cardiff. The town, which stands on a hill commanding a view of the lovely vale of Glamorgan, the Bristol Channel, and the Devonshire hills, consists of only a few narrow winding streets. The church, dedicated to the three saints, is a large edifice in the Norman style. The most important modern buildings are the town-hall and market-house. There are remains of an old castle and of a monastery in the immediate vicinity of the town. The trade is unimportant; but coal, iron, and lead are found in the vicinity, and sent to Cardiff for exportation. It is a contributory borough to Cardiff. Pop. (1851) 1007.

LLERENA, an old walled town of Spain, province of Estremadura, 62 miles S.E. from Badajoz. The town is mean in appearance, and in a state of decay. Pop. 4990, chiefly engaged in agriculture. Near this, on 11th April 1812, Lord Combermere routed a French force under Drouot.

LLORENTE, DON JUAN ANTONIO, a Spanish historian and ecclesiastic, was born in 1756 at Rincon del Solo, near Calahorra, in Aragon. When he had been for some time a canon at Tarragona, he was made commissioner in 1785, and in 1789 secretary of the holy office at Logroño. His situation procured him an opportunity of acquiring an extensive knowledge of the Inquisition, of which he published a "Complete History;" but this drew upon him the displeasure of that institution, and he was imprisoned for a considerable period. In 1805, however, he was again appointed to an office in the Inquisition; and in 1806 he became canon at Toledo. But as he declared himself in favour of

Llanidloes

Lloyd's.

Joseph Bonaparte, and of certain innovations in Spain, he was forced to quit that country on the return of Ferdinand VII., and proceeded to Paris, where he lived by his writings. He was banished from France, and died on his way to Madrid in 1823. Besides the above-mentioned *History of the Inquisition*, which was published in Paris, 1817, 4 vols., his principal works are,—*Noticias Historicas de las tres Provincias Bascongadas*, Madrid, 1806–8, 5 vols.; *Memoirs relative to the History of the Spanish Revolution*, Paris, 1815–19, 3 vols.; *History of the Popes*, &c.

LLOUGHOR (Welsh, *Lluchwr*, supposed by some to be the ancient *Leucarum*), a parliamentary borough and port of S. Wales, Glamorganshire, on the E. bank of the Lloughor River, near its mouth, 7 miles W.N.W. of Swansea, with which it is connected by railway, and to which it is a sub-port. A very inconvenient ferry, long established here, has been superseded by a wooden bridge. Vessels of 200 tons can come up to the town. In the vicinity are collieries and copper-works. Lloughor is a contributory borough to Swansea. Pop. (1851) 821.

LLOYD, WILLIAM, Bishop of Worcester, the son of the rector of Tilehurst in Berkshire, was born there on 18th August 1627. He received his elementary education from his father, and at the age of eleven entered Oriel College, Oxford. Shortly afterwards he became a scholar of Jesus College, and was chosen Bachelor of Arts in 1642, and Master of Arts in 1646. In 1648 he was ordained deacon, and, after living in Berkshire as tutor in a gentleman's family, was presented in 1654 to the rectory of Bradwell. A dispute about the right of presentation soon induced him to resign this benefice. Ordained a priest in 1665 he was appointed in 1666 chaplain in ordinary to Charles II.; and in the following year became a Doctor of Divinity. After passing through several of the lower grades of church preferment, he was installed in 1672 dean of Bangor; and in 1676 was presented by the crown to the vicarage of St Martin's-in-the-Fields, the greatest cure in England. He was promoted to the see of St Asaph in 1680; and was one of the seven bishops who were imprisoned in the Tower in 1688, for refusing to publish in their pulpits the king's declaration for liberty of conscience. A thorough-going supporter of the Revolution, Lloyd was appointed almoner to William and Mary soon after their arrival in England. In 1692 he was translated to the see of Coventry and Lichfield; but was promoted in 1699 to the bishopric of Worcester, vacant by the death of Stillingfleet. He died at Hartlebury Castle, on the 30th August 1717.

Bishop Lloyd contributed many pamphlets to the controversy against Popery that was agitated during his time. Besides a few other tracts on ecclesiastical subjects, and several sermons, he published *A Chronological Account of the Life of Pythagoras and of his famous Contemporaries*, London, 1699, 8vo; and left unfinished *A Dissertation upon Daniel's Seventy Weeks*, and *A System of Chronology*. His friend Dr Burnet, in the *History of His Own Time*, eulogises Lloyd's amiable disposition, his ample and accurate knowledge, especially in chronology, and his skill as a Biblical critic.

LLOYD'S, a number of rooms in the Royal Exchange of London, frequented by underwriters, merchants, shipowners, ship and insurance brokers, and others, chiefly for the purpose of obtaining shipping intelligence, and of transacting business connected with marine insurance. The principal room is that of the Underwriters, in which two enormous ledgers lie constantly open,—the one containing notices of *speaking*, or ships spoken with, and arrivals of vessels at their various destinations; the other recording disasters at sea. All intelligence is entered immediately upon its reception, without removing the ledgers from their places, in order

Lloyd's.

that they may at any moment be inspected by those interested in their contents. At the inner end of the room is an ingenious piece of mechanism, by means of which the indications of an anemometer and an anemoscope are inscribed every hour in the twenty-four, by a couple of pencils, upon a sheet of white paper. The advantage to the underwriter, in the conduct of his business, of this information respecting the force and the direction of the wind, can scarcely be over-estimated. The underwriters are persons who, for a premium, grant an indemnity to merchants against risks by sea; and they are so called from the custom of *writing* their names *under*, or at the foot of, the policies of insurance. The method of *effecting* an insurance at Lloyd's is the following:—When a broker receives an order to insure interest to a certain amount in a particular ship, he writes upon a slip of paper the name of the vessel, the master's name, the nature of the voyage, the subject to be insured and its value, and any other information which the circumstances of the case may require. He then offers the risk to different underwriters until the value of the interest to be insured is exhausted, each underwriter subscribing his name opposite to the amount he engages to insure, and all agreeing to accept a uniform premium. The insurance is now virtually effected; the stamped policy being afterwards extended from this slip. This distribution of the risk among many individuals is, of course, very conducive both to the solvency of the underwriter and to the security of the insured. The number of underwriters is under 200; but some idea of the immense amount of insurance business done at Lloyd's may be derived from the fact, that the value of the interest annually insured at present is estimated at about £40,000,000. No person is permitted to transact business at Lloyd's as an underwriter or insurance-broker, until he shall have been duly admitted as a member, and shall have paid an entrance-fee. Communicating with the Underwriters' Room is the Chart Room. Here a valuable collection of charts, and the shipping intelligence as originally received, are carefully arranged, so as to be at all times easy of access. In this room also lie, for the use of members, four ledgers, in which the names of ships are arranged in alphabetical order, each name having under it all the information possessed regarding the vessel. The Merchants' Room is a place of resort for general news; it is, in fact, a news or reading room. The Captains' Room is employed as an auction-room for sales of ships, &c. Every person who enjoys the privilege of frequenting Lloyd's pays a fixed annual subscription.

The shipping intelligence received at Lloyd's is furnished by agents, who are appointed for the purpose; and as there is scarcely a port of any consequence where one is not resident, their number is very large. The information which each transmits to headquarters is regular, accurate, and complete. It is furnished by means of *letters*, signed by the agents, and by means of the newspapers and shipping lists which are published at the various ports;—the intelligence thus received consisting not only of a list of vessels which had arrived at, and which had sailed from, the particular ports, together with their accomplished and intended voyages, and of casualties which had occurred at or near the ports, but also of notices of ships spoken with, and of casualties at sea, furnished by vessels. No salary attaches to the office of agent for Lloyd's; the labour involved being amply recompensed by the business which it commands, and by the credit which the appointment confers upon its holder as a person of worth and respectability.

The intelligence, besides being made known to the members of Lloyd's by means of the ledgers, of which we have already spoken, is published every afternoon in *Lloyd's List* for diffusion over the country.

The management of Lloyd's lies with the subscribers, who select a committee from their number for the purpose, called the "Committee for managing the affairs of Lloyd's."

Lloyd's This committee appoints the agents and the officials of the establishment. The expenses connected with the establishment are defrayed by the fees and annual subscriptions.

Loango. The designation *Lloyd's* originated with a person of the name of Lloyd, who kept a coffee-house in Abchurch Lane, Lombard Street. From the vicinity of this house to the Old Royal Exchange, it speedily became a rendezvous of merchants for news, and for the transaction of business. It was afterwards removed to Pope's Head Alley, and thence again, in 1774, to the Royal Exchange. After the destruction of the Exchange in 1838 by fire, which originated in Lloyd's, the business was carried on in the South Sea House, in Old Broad Street, where it remained until the opening of the present Royal Exchange in 1844, when it was finally removed to its present splendid apartments. Similar establishments exist in our principal seaports.

LLOYD'S Register of British and Foreign Shipping, a volume published annually, and furnishing information respecting the nature of vessels, their class, place where built, materials, owners, captains, age, repairs, &c. The ships are registered according to the reports of salaried agents, appointed at various ports. The office of this *Register* is in White Lion Court, Cornhill, and is quite distinct from Lloyd's of the Exchange.

LO, St. a town of France, the capital of the department of Manche, is situate on the River Vire, 157 miles N.W. from Paris. In the central part of the town, occupying the top of a rocky eminence, is a square containing several of the principal buildings, while several irregular streets diverge from it, and cover the sides of the hill. The only structures of note are,—the Church of St Thomas, now used as a corn-market; the Church of St Croix, an ancient edifice in the early Norman style; and the Cathedral of Notre-Dame, defective and irregular in its architecture, but possessing two imposing towers and finely-painted windows. There are also a museum, a prefecture, a communal college, and a bridge of six arches over the Vire. The square called Champ de Mars is adorned with avenues of trees. Ribbons, linen, lace, drugget, and leather are manufactured; and there are some bleachfields and dye-works. Cavalry horses and cattle form the staples of trade. St Lo is the seat of tribunals of original jurisdiction and commerce, and of a chamber of manufactures. Pop. (1851) 9156.

LOANDA, an island situate opposite the city of St Paul de Loanda, at the distance of a mile. It is about 18 miles long by 1 broad. Besides the country houses of some of the wealthier persons in the city, the island has a number of villages. It produces abundant pasture for sheep and goats.

LOANDA, ST PAUL DE, a city on the coast of Angola, S.W. Africa, and the capital of the Portuguese settlements in this part of Africa, S. Lat. 8. 48., E. Long. 13. 8. It is built partly upon an eminence and partly on the sea-shore; the latter being occupied, for the most part, by the hovels of the black population. Loanda is the see of a bishop; and it was formerly celebrated for a cathedral, a very large Jesuit's college, and many other ecclesiastical buildings, most of which are now in ruins. It is defended by a large citadel and two smaller batteries. There is an excellent harbour about $3\frac{1}{2}$ miles long. The climate, which is very hot in summer, is yet considerably moderated by breezes from the sea. The country in the immediate vicinity produces large quantities of vegetables, fruit, and cattle; and water, which was at one period very scarce, is now brought regularly in boats from the Benga. Ivory and bees'-wax are exported. Pop. about 5000.

LOANGO, a country in the S.W. of Africa, stretching along the coasts of the Atlantic, between the equator and the River Zaire, bounded on the N. by Mayomba, and on the S. by Congo. Loango, the chief town, is, in S. Lat. 4. 39, E. Long. 12. 17. Along the coasts the country is

flat, and of great fertility. In some places it is said to yield three harvests in the year. Little is known of the interior, but many of the mountain ranges are said to be very fertile. The lakes and rivers are richly stocked with fish; the forests abound with game; and, in some places, panthers, leopards, elephants, apes, and antelopes are to be found; but horses and cows do not thrive. The only minerals of importance are iron and copper. Palm trees, sugar-cane, maize, pulse, yams, and potatoes are the principal vegetable productions. In some places the climate is good, in others it is said to be very unhealthy; there is, on the whole, little rain, but dew falls in large quantities. The power of the king is of the most absolute description. His majesty resides in Loango, the capital; and although there are many chiefs in the country who have considerable influence, he is regarded as the supreme authority. The revenue is principally derived from the sale of slaves.

LOBO, JEROME, a Jesuit missionary, was born in Lisbon in 1593, and entered the Order of Jesus at the age of sixteen. In 1621 he was ordered to resign the chair which he occupied in the College of Coimbra, and to repair as a missionary to India. After much delay, caused by adverse weather, he set sail in 1622, and arrived in the same year at Goa. With the intent of proceeding to Abyssinia as a missionary, he left India in 1624; but after disembarking on the coast of Mombas, and attempting to reach his destination by land, was forced to return. Repeating the attempt in the ensuing year, in concert with Mendez, the newly-appointed Patriarch of Ethiopia, and eight missionaries, Lobo landed on the coast of the Red Sea, and settled down in Abyssinia as superintendent of the missions in the state of Tigré. Here he remained for some years, until death deprived the Catholics of their protector, the Emperor Segued. Forced by persecution to leave the kingdom, in 1634 Lobo fell, along with his companions, into the hands of the Turks at Masowah, and was sent by them to India, to procure a ransom for his imprisoned fellow-missionaries. This object he gained, and at the same time endeavoured, though without avail, to persuade the Portuguese viceroy to send an armament against Abyssinia. Intent upon accomplishing this cherished project he embarked for Portugal, and after he had been shipwrecked on the coast of Natal, and captured by pirates, arrived at Lisbon. Neither at this city, however, nor at Madrid and Paris, was any countenance given to Lobo's plan for Christianizing Abyssinia by the aid of arms. He accordingly returned to India in 1640, and was elected rector, and afterwards provincial of the Jesuits at Goa. Returning to his native city in 1656, he continued there till his death in 1678. His *History of Ethiopia*, published in 1659, was translated from the MS. into French by the Abbé Legrande, Paris, 1728. Added to it was a supplement containing a history of the missions and expeditions to Abyssinia after Lobo's time, and several dissertations on the history and customs of that country. An English translation of Legrande's edition was published by Dr. Johnson in 1735, and reprinted in 1789.

LOBOS, or SEAL ISLANDS, two groups of guano islands in the Pacific Ocean, lying off the coast of Peru. The landward and northern group are about 20 miles W. of the mainland, in S. Lat. 6. 29., W. Long. 80. 53., and consist of one large island, 5 miles long by 2 in breadth, with several rocky islets. The seaward group lie about 38 miles from the mainland, in S. Lat. 6. 56., W. Long. 80. 55., and consist of two islands of about the same size, viz., 1 mile long by 1 in breadth, and separated from each other by a narrow channel. Both belong to Peru, although unsuccessful attempts have been made at various times by the United States government and private companies to obtain possession of them. On the N. group there is estimated to be a deposit of guano of about 400,000 tons, and on the other

Lobo
||
Lobos.

Locarno
||
Lochmaben

islands of more than 200,000 tons. The only inhabitants are those employed in the shipment of the manure, and consist chiefly of Indians and Chinese.

LOCARNO, a small town of Switzerland, and one of the three capitals of the canton of Tessin, is pleasantly situated at the head of Lake Maggiore, 8 miles S.W. of Bellinzona. It contains a government house, an old castle, and several churches. The climate is unhealthy, owing to the quantity of silt in the immediate vicinity, brought down by the numerous torrents which join the lake here. The inhabitants speak an Italian dialect. In March 1553 more than a hundred persons were expelled from the town for refusing to become Roman Catholics. Since then Locarno has decayed, as it was deprived by that expulsion of great part of its labouring population. Pop. 2676.

LOCATELLI, PIETRO, born at Bergamo in 1693, was sent when very young to study the violin under Corelli at Rome. His early career has not been recorded; but it appears that, after travelling as a distinguished violinist in Italy, Germany, France, and England, he fixed his residence at Amsterdam, where he established a public concert. At his death in 1764, the members of the Amateur Society of Amsterdam went into mourning. His compositions are full of new passages and difficulties unknown before his time, but they contain also many graceful and pleasing movements. His *Capricci* are excessively difficult; and it is evident that the celebrated Paganini had studied them carefully, and availed himself of the inventions contained in them. In command of the violin and knowledge of its resources, Locatelli far excelled all other violinists of that period. The Count Benvenuto di San Raffaele, royal director of studies at Turin, and an excellent violinist, published in 1784 *Letters on the Violin (Lettere, &c.)*, in which he writes in the highest terms of Locatelli's playing. The following list of Locatelli's published works is taken by the writer of this article from the list (down to opera 6) prefixed by Locatelli himself to his sixth work. The *Privilege*, at the end of the volume, is in Dutch, and dated at the Hague, July 24th 1731; "Opera 1^{ma}, XII. *Concerti*; Op. 2^a, XII. *Sonate per il Flauto Traversiere Solo e Basso*; Op. 3^a, *L'Arte del Violino, XII. Concerti con XXIV. Capricci*; Op. 4^a, *Sei Introduzioni Teatrali, e Sei Concerti*; Op. 5^a, *Sei Sonate a tre, a due Flanti Traversieri, con due Bassi*; Op. 6^a, XII. *Sonate a Violino Solo e Basso*. From this list and the *Privilege*, it is clear that Locatelli's Opera 6^{ta} was not first published in 1737, as has been erroneously stated, but in 1731. An edition was published at Paris in 1801. Op. 7^{ma}, VI. *Concerti a quattro*; Op. 8^{va}, VI. *Sonate a tre, due Violini e Basso*; Op. 9^{na}, *L'arte di nuova Modulazione*, the latest edition of which was published by Frey, at Paris, under the title of *Caprices*; Op. 10^{ma}, *Contrasto Armonico, Concerti a quattro*. (G. F. G.)

LOCATIO ET CONDUCTIO, is a contract made merely by consent, without employing any definite form of agreement. He who promises the use of a thing is *locator*; he who promises a sum of money for the use of it is *conductor*. Again, in giving services, or the result of labour for a fixed price, the person for whom the service is done is called *locator*; the person doing it *conductor* or *redemptor*.

LOCHGILPHEAD, a large village of Scotland, county Argyll, at the head of Loch Gilp, an arm of Loch Fine, 2 miles N. of the mouth of the Crinan Canal at Ardrishaig. It has churches belonging to the Established and other denominations, and a district gaol. The inhabitants are chiefly employed in the herring-fishery; and daily communication is maintained with Glasgow by steamers. Pop. (1851) 1703.

LOCHMABEN, a royal and parliamentary burgh of Scotland, Dumfriesshire, nearly surrounded by a number of small lakes, 8 miles N.E. of Dumfries. It has an Estab-

lished, a Free, and a United Presbyterian church, a town-house, and a young men's literary institute. The inhabitants are chiefly employed in the making of hosiery for the Dumfries manufacturers. Near the town are the scanty remains of an old castle, said to be the birthplace of Robert I. of Scotland. Lochmaben was made a royal burgh by that sovereign, and is governed by a provost, 3 bailies, and 9 councillors. It also returns one member to parliament in conjunction with the burghs of Dumfries, Annan, Kirkcudbright, and Sanquhar. Pop. (1851) 1092.

LOCHWINNOCH, a small manufacturing town of Scotland, Renfrewshire, on Calder Water, near Semple Lake, 14 miles W.S.W. of Glasgow by rail. It consists of four main streets, and contains several churches and schools. The inhabitants are chiefly employed in the cotton and wool mills of the place. Pop. (1851) 2271.

LOCK, MATTHEW, an English musical composer of considerable reputation and of eminent merit, was born at Exeter in the early part of the seventeenth century. The precise date of his birth is not known; some, however, are of opinion that it was in 1635. Connected with the choir of the cathedral of his native city, he received the rudiments of his musical knowledge from Wake, who then held the office of organist in that place. Lock had afterwards the good fortune to make the acquaintance of Edward Gibbons, under whom he completed those studies for which he had already contracted a passion under the instructions of the organist of Exeter. On the public entry of Charles II. into London, Lock was employed to write the music for that notable occasion, and performed his task so well, and with so much satisfaction to those in authority, that he was soon afterwards appointed composer to that prince. The first piece that appeared under his name was "A little consort of Three Parts, for Viols or Violins." There is also a very pleasing piece of vocal music by him entitled, "Ne'er trouble thyself about Times or their Turnings," among the collection of glees to be met with in Playford's *Catch that Catch can*.

In 1673 Lock came before the public in a somewhat different phasis of his art, and established for himself a true and abiding reputation. He wrote the instrumental music in Shakspeare's play of the *Tempest*, as it appeared during that year, and may be regarded, indeed, as the first musician in England who thus devoted his talents to the stage. He published the overture and airs to the *Psyche* of Shadwell in 1675, with an exceedingly violent preface, strongly marked by that unfortunate irascibility of which his cotemporaries found so much reason to complain.

It was about this time that the Rev. Thomas Salmon, A.M., of Trinity College, Oxford, and a notable mathematician, came forward with a plan for greatly improving musical notation. This proposal was a very desirable one, calculated to remove many of the difficulties which attend that branch of the art; and whether of the most perfect kind or not, would at least have cleared the way for a more complete and decided scheme of notation than the musical world as yet had the good fortune to obtain. It was not destined, however, to meet with the approval of the vehement composer of Exeter. In his pamphlet, entitled *Observations on a late Book called an Essay, &c.*, Lock loaded the scheme and its author together with the bitterest abuse, displaying an amount of personal feeling which led to the suspicion that he gave his opposition to the beneficial proposal of the mathematician more from motives of individual interest than from an unprejudiced conviction of its utility. A number of Lock's sacred pieces are to be found in the *Harmonia Sacra*, and in Boyce's *Collection of Cathedral Music*; but the great foundation on which his fame was reared is his music in *Macbeth*, "a lasting monument," says his biographer, "of the author's creative power and judgment." Lock died in 1677.

LOCK.

Lock.

A Lock may be defined to be any kind of fastening which is intended not to be opened except by one particular instrument, called the key, or by some secret method of manipulation. The earliest lock of which the construction is known is the Egyptian, which was used 4000 years ago. In this drawing (fig. 1), *aa* is the body of the lock, *bb* the bolt, and *cc* the key. The three pins *p, p, p* drop into three holes in the bolt when it is pushed in, and so hold it fast; and they are raised again by putting in the key through the large hole in the bolt, and raising it a little, so that the pins in the key push the locking-pins up out of the way of the bolt. The security of this is very small, as it is easy enough to find the places of the pins by pushing in a bit of wood covered with clay or tallow, on which the holes will mark themselves; and the depth can easily be got by trial.

Fig. 1.

Mr Chubb, the well known lock-maker, has shown us a wooden Chinese lock which is very superior to the Egyptian, and, in fact, founded on exactly the same principle as the Bramah lock, which long enjoyed the reputation of being the most secure lock ever invented; for it has sliders or tumblers of different lengths, and cannot be opened unless they are all raised to the proper heights, and no higher. Until about eighty years ago, we had no lock so good as this in England. The locks then in use (fig. 2) were nothing better than a mere bolt held in its place, either shut or open, by a spring *b*, which pressed it down, and so held it at either one end or the other of the convex notch *aa*; and the only impediment to opening it was the wards which the key had to pass before it could turn in the key-hole. But you could always find the shape of the wards by merely putting in a blank key covered with wax, and pressing it against them; and when you had done so, it was by no means necessary to cut out the key into the complicated form of the wards (such as fig. 3), because no part of that key does any work except the edge *bc* farthest from the pipe *a*; and so a key of the form fig. 4 will do just as

Fig. 2.

Fig. 3.

Fig. 4.

well; and a small collection of skeleton keys, as they are called, of a few different patterns, were all the stock-in-trade that a lock-picker would require.

The common single-tumbler lock (fig. 5) was rather better than this, as it requires two operations, instead of one, to open it. The tumbler *at* turns on a pivot at *t*, and has a square pin at *a*, which drops into a notch in the bolt

bb, either when it is quite open or quite shut, and the tumbler must be lifted by the key before the bolt can be moved again. But this, also, is very easy, unless the lock is so made that the tumbler will go into another notch in the bolt if it is lifted too high, as in the lock we shall now describe, and which is the foundation of all the modern improvements in lock-making.

Fig. 5.

Common
Tumbler
Lock.

Barron's Lock.—Fig. 6 is a front view, and fig. 7 a horizontal section, of Barron's lock, which was patented in the year 1778. First consider it with reference to one tumbler, *at*, only.

Fig. 6.

You see that unless the square pin *a* is lifted by the key to the proper height, and no higher, the bolt cannot move, and that alone adds very considerably to the difficulty of picking, except by a method not discovered for many years after. But besides that, Mr Barron added another tumbler, and unless both were raised at once to the proper height, and no higher, the lock could not be

Fig. 7.

opened. We are not aware that Barron himself ever went beyond two tumblers; but the principle of the many-tumblered lock is undoubtedly his, and nothing that was added to it for nearly eighty years afterwards made any material addition to its security. But instead of making a separate pin to each tumbler, and a corresponding number of notches in the bolt, the simpler plan was adopted by other makers of putting what is called the *gating*, in the tumblers, and a single pin in the bolt, which is then called the *stump*; this will be shown presently in the drawing of Chubb's still more famous lock. The face, or working edge, of the key of a many-tumblered lock assumes this form (fig. 8), the steps corresponding to the different heights to which the tumblers have to be raised, and one of them acting on the bolt, and they may have a much wider range of difference than in this figure. The key here drawn is also one with the wards of such a shape that no skeleton except itself can pass them. The form, however, can be got in the usual way by a wax impression; and as it weakens the key very much, and is expensive to cut, it is not often used.

Fig. 8.

Bramah's Lock.—The next lock of any importance was Bramah's the celebrated lock originally patented, just ten years after Lock.

Barron's, by the late Mr Joseph Bramah, who came up to London from Barnsley as a joiner, and raised himself to eminence by the invention of this lock, of the machine for numbering bank-notes, the beer-engine, the water-closet, the pencil-cases called "ever-pointed," and, above all, the hydraulic press—an invention which, like Nasmyth's steam hammer, extended the powers of man beyond what before had been conceived possible. In figures 9 and 10, *aaaa* is the outer barrel of the lock, which is screwed to, or

Bramah's Lock. cast with the plate; *cccc* is a cylinder, or inner barrel, turning within the other. It is shown separately at fig.

Fig. 9.

11; and fig. 12 is a cross section of it, the black ring being the keyhole, and the light spot in the middle the

Fig. 10.

drill-pin, which goes into the key. The short pin *b*, in figs. 9, 10, 11, is set in the end of the cylinder, near its edge; and when the cylinder turns round, that pin shoots or draws the bolt, by acting in a slit of the form shown in fig. 13. The security of the lock depends upon a number of sliders, *s*, of which the shape is shown in fig. 14, and the cross section in fig. 12. They are made of plates of steel doubled, and sprung open a little, so as to make them move with a little friction in the slits of the cylinder or revolving barrel in which they lie, and are pressed up against the cap of the lock by a spiral spring. They are shown so pressed up in fig. 9, and pressed down by the key in fig. 10. There is a deep groove cut round the barrel; and in each of the sliders there is a deep notch which can be pushed down to that place in the barrel by a key slit to the proper depth; and it is evident that when all the sliders are pushed down to that position, the barrel will present the appearance of having no sliders in it. A steel plate (fig. 15), made in two pieces in order to get it on, embraces the barrel at the place where the groove is, having notches in it corresponding to the sliders,

Fig. 11.

Fig. 12.

and is fixed to the body of the lock by two screws marked *d, d* in figs. 9, 10, and 15. When the sliders are pushed up by the spring, they fill the notches in the plate, and prevent the barrel from turning; but when they are pushed down by the key, the notches in the sliders all lie in the plane of the plate, and so the barrel can turn with the key, and the pin *b* in the end of it drives the bolt as before described. The key, as every one knows who has seen a Bramah key, has a *bit*, *k*, sticking out from the pipe, the use of which is to fix the depth to which it is to be pushed in, and then, as the bit

Fig. 13.

Fig. 14.

Fig. 15.

slips under the cap of the lock, it keeps the key at the same depth while you are turning it.

This was the construction of the lock for a good many years, and Mr Bramah pronounced it in that state "not to be within the range of art to produce a key, or other instrument, by which a lock on this principle can be opened." It was found, however, long before the defeat of the improved challenge Bramah Lock by Mr Hobbs in 1851, that the inventor had made the common mistake of pronouncing that to be impossible which he only did not see how to do himself. As it has been generally supposed that what is called the tentative method of lock-picking was unknown here before it came over from America in the year of the great Exhibition, we must remind our readers that it was described in the last edition of this work nearly thirty years ago; though, no less fortunately than strangely, the lock-picking fraternity were not of sufficiently literary habits to make themselves acquainted with it. Mr Hobbs, it is true, carried the process farther than had been supposed possible before; but all the Barron and Chubb, and other many-tumbled locks, which were supposed impregnable, might long ago have been opened by anybody who had paid attention to the method by which the Bramah locks were known to have been picked some forty years ago, before the introduction of the *false notches*, designed by Mr Russell in 1817, then one of Mr Bramah's workmen. If you apply backward pressure to the bolt of a tumbler lock when locked, or twisting pressure to the barrel of a Bramah lock, first pressing down the spiral spring, there will be a greater pressure felt against some of the tumblers or sliders than against others, in consequence of inevitable inequalities of workmanship; and if you keep the pressure up, and gently move any of the tumblers or sliders on which the pressure is felt, you will at last get it to some point where it feels loose. That may or may not be the exact place to which the key ought to lift it; but as soon as you feel it loose, leave it alone; it will not fall again, as the friction is sufficient to prevent it; and, if necessary, you may fix it there by a proper instrument, or measure the depth, and keep the measure till you begin again. Then try another tumbler which feels tight, and raise it till it also feels loose. And if you go on in that way, always leaving the loose tumblers alone, and raising the one which feels tight, they will at last all be got into the position of complete freedom, *i.e.*, to

Bramah's
Lock.

Bramah's
Lock.

the place where the stump of the bolt can pass them. The operation is just the same in principle in the Bramah lock and in tumbler locks: only, as all the sliders are acted on by one spring in the Bramah as now made, you need only just push down that spring, and hold it there, and then the sliders may be moved freely either way by means of a hook or a small pair of self-acting forceps to pull them up if they accidentally get pushed too far. At first each slider had a separate spring.

False
notches.

But if the sliders have some false notches in them not so deep as the true ones (see fig. 14), and the corners of the notches in the plate *dd* are cut out a little (as in fig. 15), then you might by trial get all the sliders into such a position that the barrel could turn a very little, but no more; and when it is turned that little, you cannot push the sliders in any farther, and so (as was long supposed) the tentative process is defeated; and undoubtedly it is made much more troublesome, but it only requires more time and patience. You can still feel that the pressure is greater against some one or more of the tumblers or sliders than against others; and wherever that is the case, you know that it must be at a false notch, and not the true one, for a true one gives no pressure at all. Proceeding in this way, Mr Hobbs opened the challenge-lock with eighteen sliders, or guards, which had hung in Messrs Bramah's window for many years, in nineteen hours, and would have done it sooner, but that one of his instruments broke in the lock. He afterwards repeated the operation three times within the hour, in the presence of the arbitrators; and we have seen him open a more recent one with eight sliders in four minutes, by means of an instrument which is equivalent to a Bramah key with adjustable slits, which are set to the sliders as he goes on feeling them and getting their depths. It has been stated as an advantage of the Bramah lock, that an impression cannot be taken from it. This is a great mistake. Mr Chubb showed us a small instrument, which a man could hold in his hand without it being seen, and by which an exact impression of the depths of any Bramah key, whose number of slits is known beforehand, can be taken in a moment, and the other end of the instrument then becomes a key which will open the lock at once.

It is moreover to be remembered, that thieves do not always confine themselves to the conditions of a challenge, in which force and injury to the lock are of course prohibited; and if a lock can be easily opened by tearing out its entrails, it is of very little use to say that it would have defied all the arts of polite lock-picking; and in this respect the Bramah lock is singularly deficient; for if the exposed cap or nozzle of the key-hole is cut off, as it easily may be, or the hole widened out by a centre-bit, the sliders can all be pulled out, and there is an end of the lock. But, as a protection against picking by pressure without violence, Mr E. B. Denison suggested an alteration, of which a specimen was made in 1853 by Messrs Mordan (who are now the largest manufacturers of Bramah locks), on the principle of Mr Hobbs's moveable stump for tumbler locks. The locking-plate is not screwed to the body of the lock, but is left free to turn a little; and if it is turned by putting any pressure on it from the sliders, it pushes a click CC (fig. 16) into a notch in the barrel and holds it fast, and so no pressure of the sliders can be felt. In this case, the locking-plate is made in one piece, and the barrel in two. If that contrivance had existed in Messrs Bramah's challenge-lock, it could not have been picked by Mr Hobbs's method. However, locks for securing property well worth stealing must be safe against rude as well as polite lock-picking, and this the Bramah

Fig. 16.

lock hardly can be made; and therefore it must be admitted, that, even with the above-mentioned improvement, it is now behind the requirements of the age, though the smallness of the key, and the cheapness with which they can be manufactured and sold to the trade (though they are not yet sold by retail as cheap as some other better locks), will probably enable them to keep their place for some time.

Bramah's
Lock.

Inside and Outside Locks.—Locks for drawers, closets, iron chests, and the like, are only required to lock on one side, and their keys are therefore made with a pipe, which slips on to, and turns on a pin in the lock, called the *drill-pin*. But doors which have to be locked sometimes on one side, and sometimes on the other, cannot have their keys made in this way; but the key is solid, and its plug or stem being thicker than the flat part or web, it acts as an axis fitting into the upper part of the key-hole, though that hole does not completely inclose it. All keys for these inside and outside locks must be symmetrical, or alike on each side of a line through their middle, in order to fit the lock either way, which limits the variety of the tumblers in the case of many-tumbled locks. A Bramah lock, to open on both sides, must be made double, with one set of sliders to push in from one side of the door, and the other set from the other side; and, consequently, they are very seldom used for this purpose. It may be convenient to observe, that when we use the term Bramah lock, we mean a lock of that construction; for the patent having long ago expired, they may be made by anybody, just as Chubb's lock may, though nobody but the representatives of the original patentees has a right to apply the name *Bramah* or *Chubb* to them; and therefore Messrs Mordan, for instance, rightly call them by their own name, though their locks are the same as Bramah's, except that they generally make the number of sliders odd, while Messrs Bramah make it even.

Cotterill's Lock.—The lock of Mr Cotterill of Birmingham is on the same principle as Bramah's, the difference being, that the sliders are pushed out radially by a very thick key with inclined slits in it. The locking-plate is a ring instead of a flat plate, and the notches in the sliders have all to be brought into the same circle, to be able to pass along the ring. Some of the sliders are made into what are called detectors, being held by a spring catch, if they are pushed out too far. This is the primary form of Cotterill's lock; and in that form it is evidently quite as easy to pick as the commonest form of Bramah lock, and easier, because the

Fig. 17.

range of the sliders is necessarily very small, as the extreme range can be no more than the thickness (not the diameter)

Cotterill's
Locks.

of the key-pipe. But Mr Cotterill afterwards added a second ring X (fig. 17) outside the fixed locking-ring RR; and in that outer ring you observe that the notches are not quite opposite to the ends of the sliders, some of which are bevelled; and therefore, when pushed out by the key, they will force themselves into the notches of the outer ring, and turn it a little against the resistance of a spring, which tends to keep it in the position shown in the drawing with reference to the cylinders and sliders. When it is so pushed a little out of the way by the bevelled sliders, the square-ended ones can enter the holes then opposite to them, and so carry their own notches into the position to pass the inner or fixed ring, and then the cylinder can turn, and it carries the outer ring with it. Moreover, in the latest form of this lock, the inner ring is not absolutely fixed, but has a little play, like the plate of the improved Bramah lock in fig. 16; and by the side of it there is a click, CC, which any slight turning of the ring brings into action, and makes it lock the ring fast. This appears, from Mr Cotterill's description and drawing, to be just the same contrivance which we have already described as being applied by Mr Denison to the Bramah lock to prevent feeling the pressure of the sliders on the locking-plate; only this appears to lock into the ring itself, and therefore would not prevent the pressure from being felt; whereas Mr Denison's click for the Bramah lock fastens the barrel, and does prevent the pressure. But that could easily be done in the same way in Mr Cotterill's lock; and, if so done, it would, as far as we can see, be of much more value than the second ring, as we shall explain presently. The entrails of this lock could not be taken out, like Bramah's, by merely cutting off the nozzle.

This lock acquired some celebrity, from having defeated Mr Hobbs in a challenge to pick it. But from the printed account of the affair, sent to us by Mr Cotterill himself, it is clear that that failure proved nothing, except that Mr Hobbs was taken by surprise, and supposed that he was picking one of Cotterill's locks as they had been made before the invention of the second ring, and such as he had publicly exhibited a mode of picking with merely a piece of wood; whereas the lock in the trial contained these other arrangements, which Mr Hobbs knew nothing of. It is certainly added, in the printed account, that, when he did see the additions, he confessed that he did not then see how such a lock was to be picked, and declined to try it. Whether it really is invincible in its present state we are not able to say, not professing to be lock-pickers ourselves; but it does appear to us that the inventor considerably overstates the difficulty when he says all the sliders must be moved together; for it seems plain that pushing out any two nearly opposite sliders with the bevelled ends would turn the outer ring as well as a dozen; and as soon as it is turned a little it is of no further use. No doubt all the sliders must be at last brought together into the proper position, as they must in any other lock; but that is a very different thing from requiring them all to move simultaneously into that position. And whether the lock is impregnable or not, we should imagine that the great thickness and weight of the key, which is necessary to get even a moderate range in the sliders, would generally be considered an objection to it, as we have the best authority for saying, that in some other cases the highest amount of supposed security will not induce even bankers to adopt locks with large keys.

Letter
Locks.

Letter Locks.—It used to be supposed, some years ago, that locks which could only be opened by setting a number of rings or discs to a particular combination of letters could not possibly be opened by anybody who was not in possession of the secret; and hence they were also called *puzzle-locks*. At first they were made with a fixed combination, which could not be changed. Afterwards the rings were made double, the inner one having the notch in

it which the bolt had to pass, and the outer one capable of being fitted on to the inner in any position, by unscrewing some part of the lock, so that you might set them to any combination you like. This was the first instance of a changeable lock, of which we shall have more to say at the end of this article. But it was afterwards found that these puzzle-locks have just the same vulnerable point as all our locks had until lately, viz., that the pressure of the bolt can be felt on some of the rings more than on the others; and Mr Hobbs says emphatically, in the *Rudimentary Treatise on Locks*, "wherever that is the case, that lock can be picked." We have heard an amusing account of his opening, in a few minutes, a great dial lock on an iron door at Liverpool; and also opening a French lock in the Great Exhibition, and setting it to a new combination, so that the exhibitor himself could not open it. Besides this defect, these locks have very much gone out of use on account of their being troublesome to handle, and perhaps also from the risk of forgetting the combination to which it was set last, if the lock has been left for some time; and therefore we do not think it necessary to go further into the details of their construction: the principle of it we have described sufficiently to make it intelligible.

Letter
Locks.

Chubb's Locks.—Of the multitude of locks which have Chubb's been made on the many-tumbler principle, originally invented by Barron, none have enjoyed so much celebrity as Chubb's, partly from their superior workmanship and use of more tumblers than usual, and perhaps still more from the late Mr Chubb, or his brother, who took out their first patent in 1818, having had the good fortune to hit upon the name *Detector* for a certain part of the machinery, which, besides adding to the security against any mode of picking then known, also captivated the public with the idea of discovering if anybody had been tampering with the lock, though the operator might depart in ignorance that he had left any trace of his attempt behind him. It is remarkable that the detector was not even then a new invention; for a lock exactly the same in principle, but slightly different in arrangement, had been previously made by a Mr Ruxton. In the same way false notches were used in Strutt's tumbler lock above thirty years before they were re-invented by Chubb and others, with the idea of defeating the tentative method of picking by them. The original form of this invention is shown in fig. 18 by the lever DT,

Fig. 18.

which turns on a pin in the middle, and is acted upon at its end T by a spring S, which will evidently allow some play to the lever on either side of the corner X, but the moment it is pushed past that point, the spring will carry it farther in the same direction, like what is called in clock-work a *jamper*. In its proper position that end always remains above the turning-point; but if any one of the tumblers is raised too high, the other end D of the detector, which reaches over all the tumblers, is lifted so far that the end T is sent down below the corner, and the tooth T then falls

Chubb's
Locks.

into a notch in the bolt, and so prevents it from being drawn back, even though all the tumblers are raised properly by the right key, which at once reveals that somebody has been trying to pick the lock. The way to open it, then, is to turn the key the other way, as if to overlock the bolt: you observe a short piece of gating near the end of the tumblers, to allow the bolt to advance a little, *i.e.*, just far enough to push the tooth of the detector up again by means of its inclination there, and then the lock can be opened as usual. In Mr Chubb's more recent locks the tumbler is made in another form. The back tumbler, or the one which has to be raised highest, has a pin *d* reaching over all the others, and if any of them are overlifted, that back tumbler is also, and then a square corner *k* in it gets past the end of the detector spring *ks*, and is held up. It is set right by overlocking the bolt as before, the bolt itself raising the end *k* of the spring, and letting the tumbler fall. This form of detector is, however, inferior to the other, as it informs the picker what he has done, by the back tumbler itself being held up, which he can feel directly.

But since Mr Hobbs's mode of picking locks became known, all these detectors have become useless. Some persons have even gone so far as to say that the detector may be made a guide to picking. Whether this be so or not, the detector does not act unless some of the tumblers are raised too high, which they never are by a skilful operator on this plan, nor does it act (even if thrown by accident) against picking backwards, or feeling the way to shoot the bolt a little farther, as if to free the detector; and in this way, at any rate, the measure of the key can be taken without any hindrance from the detector. Before 1851 tumbler locks were seldom made with false notches; we remember, however, seeing a lock on an iron door, invented by a Mr Strutt many years ago, in which the tumblers were in the form of quadrants, with a very large angular motion, and a number of short or false notches and one deep one. But since that year Mr Chubb and some other makers of tumbler locks have adopted false notches in all their best locks, together with revolving curtains, which cover the straight part of the key-hole as soon as the key is turned; and barrels going down from the back of the curtain to prevent a false key or pick from turning without turning the curtain; and other obstacles, of which the object is in all cases to prevent the maintaining of pressure of the stump upon the tumblers at the same time that the tumblers themselves are moved, or, as Mr Hobbs has called it, tickled, by some other instrument. These provisions, and especially a number of small false notches (which may be got with a thick stump by serrating the end of it), undoubtedly make the locks much more difficult to pick; in fact so difficult, and requiring such nicety of instruments and manipulation, that they may be considered practically safe, except under extraordinary circumstances. But then it must be remembered that all the great robberies, of which there are several every year, do present extraordinary circumstances, and that they are never attempted except where the temptation has been made great, by the thieves seeing that they had unexpected facilities offered them. It is therefore by no means safe to assume that a lock will never be picked, merely because it would take a first-rate hand a long time to do it. The process need not be continuous. A good hand will do part of his work, and measure it, or mark it off upon his false key, one day, and more another, until it is all done, and his key ready for action at the first convenient opportunity. Recent experience has shown that your own officers, clerks, and servants are the people from whom you have most to apprehend, and they are just the people who have the most time and opportunity to perform their key-making operations undisturbed. Without going into all the mechanical details (which it is perhaps as well not to publish), it is enough to say, that the lock of the United States Bank, which was

almost as complicated as the famous one of Day and Newell, and contained all the false notches, revolving curtains, and other provisions which have been several times re-invented or put out as novelties here, was nevertheless picked for a wager.

We shall now describe the principal inventions that have been made within the last few years, with the view of defeating that tentative method of picking to which all our locks, as constructed before 1851, were and are liable; and we shall point out which of them really do effect that object, and may be regarded as absolutely secure against any mode of picking at present known; and which of them may be regarded as safe enough for ordinary purposes, though not coming up to the mark of absolute security.

Hobbs's Lock.—The invention which most directly meets the defect of all previous locks is Mr Hobbs's moveable stump, which, it must be observed, is a totally different thing from the great twenty-guinea American lock of Day and Newell, which also goes by his name here, because he makes and sells them. In Hobbs's lock, the stump is not rivetted

Fig. 19.

into the bolt as usual, but is set on the end *S* of a bent lever STP (fig. 19), which lies in a hollow of the bolt behind it, turning on a pivot in the bolt itself, and kept steady by a small friction-spring, not shown in the drawing. The stump comes through a hole in the bolt large enough to let it have a little play; and the long end *P* of the lever stands just above the edge of a square pin, which is fixed in the back plate of the lock. When the lock is locked, if you push the bolt back, you produce no sensible pressure on the tumblers, but only just enough to turn this protector lever, as Mr Hobbs calls it, on its pivot *T*, and so bring down its end *P* in front of the square pin, and then the bolt can no more be pushed back than when held by Chubb's detector. The protector is set free again by merely pushing the bolt forward with the key, without reference to the tumblers. It was found however, that in this state, the protector could be prevented from acting by a method used by Mr Hobbs himself for another purpose, *viz.*, pushing a piece of watch-spring through the key-hole, and up behind the bolt, so as to reach the protector at *P*, and keep it up while you push the bolt back; or, again, by pushing up the watch-spring between any two of the tumblers, and holding the end *S* of the protector with it, so as to press the stump against the tumblers. Both these devices, however, are prevented now by letting in a feather *FF* in a groove between the bolt and the back of the lock, which no watch-spring can pass, and also bringing a piece of the feather forward through the front gating of the tumblers just under the stump. In this form the lock is safe against any mode of picking at present known, unless the key-hole happens to be large enough to admit the inspecting method, which is this:—A person intending to pick the lock goes beforehand and smokes the bellies, or lower edges of the tumblers, through the key-hole. When the key comes, it wipes off the black on each tumbler, according to the length of the bit which raises it; and then, when the picker returns, he throws a strong light into the key-hole, and, by means of a narrow reflector put into it, reads off, as it were, the length of bit required to raise each tumbler to the proper height. This operation may sound impossible; but it is an established method of lock-picking, at least in America, where they seem to be considerably ahead of us in these matters. It requires a largish key-hole, however; and it may be prevented by any kind of revolving cylinder, which will conceal the view of the tumblers while the key-hole is open. The one that does it most completely is the eccentric cylinder, which will be described in the great American lock. The inspecting

Hobbs's
Lock.

Parnell's
Locks.

method might also be frustrated by making the acting part of the bellies of all the tumblers no longer than would be reached by the shortest bit in the key. In that case, the long bits would not begin to act at their points, but on their sides, and would leave no measure of their length upon the tumblers.

There is another lock invented by Mr Hobbs, also belonging (as far as we can see) to the absolutely secure class; but it will be more conveniently described after we have noticed the changeable key-locks.

Parnell's Locks.—The next contrivance for preventing the tentative mode of picking is that invented by Mr Parnell (fig. 20), and now sold by a Mr Puckridge, with whom Parnell was in partnership for some time, but has now left that firm, and set up

for himself at another shop, with a later invention of his own, which we shall describe presently. His first lock acquired some celebrity from a trial at law, in which it appeared that a certain Mr Goater, who worked for Mr Chubb, had

Fig. 20.

claimed 200 guineas for picking a challenge lock of Parnell's,—the fact being, that he had first clandestinely taken the cap off and made a false key, and then pretended to pick it. But the trial proved no more in favour of it than the pretended picking proved against it; for there was no proof that the lock could not be picked by other means; and we cannot think it would present much difficulty to those who can pick such locks as Jones's American bank-lock, before alluded to, though it would probably defeat the ordinary race of lock-pickers.

The most important features in this lock are, the lever E at the top, which is called a *double-action latch*. It is, in fact, Chubb's detector, with the addition of the tooth on the left hand, which falls into the bolt and prevents it from being pushed back against the tumblers, except when it is raised by them, or any one of them, just enough to clear the bolt, and no more; for if raised too high, it locks into the bolt at the other end, like Chubb's first detector. But it is evident that this is worth very little by itself; for you have only to put the pressure on the bolt, and then gently raise the lever by one of the tumblers until the bolt will either clear it completely, or, at any rate, press against some of the tumblers, and then proceed as usual. But then another lever is added. You observe a line across what appears to be the stump S. The part below the line is the real stump; but the part above it is a kind of second stump set on a tumbler behind the others, and not touched by the key, but pressed upwards by a weak spring, so that it can only rise when all the tumblers are lifted. This *self-acting lever* also ends in a square corner, which butts against the real stump when it is down; so that, if you push the bolt back, you bring the stump against the self-acting lever, and not against the tumblers. All this looks very formidable; but on examining one of these locks, it occurred to us at once, that if you only lift all the tumblers a little, so as to let the self-acting lever rise out of the way of the stump, and then (but not before) push the bolt back, you have disposed of the lever just as much as if it did not exist; and on trying it, we found the operation perfectly easy. Of course, it would require more care and delicacy to manage the "double-action latch" and the "self-acting lever" together than either of them separately; but they are only

used together in the most expensive of these locks; and, moreover, it is a maxim in lock-picking, that a mere multiplication of difficulties does not produce impossibility, and that no number of approximate or partial securities amount to one absolute security.

The mode of operation just now described will defeat equally well a self-acting tumbler, on the same principle, which Mr Chubb added to his locks soon after Mr Hobbs's demonstration, in 1851, of the insecurity of his and Bramah's, and, indeed, of all the then existing English locks. Mr Parnell (or Puckridge) also uses, in his large locks, a revolving curtain and cylinder, or barrel, which covers part of the key-hole, and the web of the key expands as it turns; for, when the key is out of the lock, it looks like a blank, with no bits projecting. But all these things, and the double-action latch too, are all old inventions, as may be seen in the *Rudimentary Treatise*, and more fully in Mr Price's large book on *Fire-proof Safes, Locks, and Keys* (published since this article was written), which is the most complete treatise on the subject ever published in this country; though even in that some of the descriptions are so brief as to be hardly intelligible, in consequence of the enormous number of inventions—nearly all patented, and most of them useless—which have been made for the improvement of locks within the last forty years. Besides being an old invention, an expanding key is very limited in the range or variety of the bits, expensive, and unpleasant to work on account of the increased friction. The pieces marked FF (in fig. 20) are called *sentinels* by the inventor, and they are intended to prevent the cylinder from turning beyond a certain point with a false key, and also to prevent the false key from getting out again. This, too, has been done before, and on the same plan, of preventing any key, whether true or false, from returning; and so, if it cannot go forward and open the lock, it is held fast, as evidence of its own intrusion, like Cassim in the cave of the Forty Thieves. But when the inventors of these things talk of the "frightful consequences" of having to smash the door in order to get the false key out, they forget that the key is not the thief, and that these consequences are rather amusing than frightful to the person who left it there, who will have the satisfaction of knowing that he has, at any rate, done as much mischief as possible, by way of paying off the owner for not providing him with a lock more easy to pick. It is also to be remembered, that if the owner himself carelessly puts a wrong key into the lock, or if there is a piece of dirt sticking to it, which may prevent it from opening the lock, the consequences are equally unpleasant. The detention apparatus clearly adds nothing to the security. If the "sentinels" really do their other duty of preventing the cylinder from turning beyond a certain point except with the true key, you want nothing more, and get nothing more, by detaining an intruding key; and if they can be held or thrown out of action (as we rather suspect they can), that, of course, would be the first thing a skilful lock-picker would do. We do not mean to say that a lock with all these complicated provisions could be picked under several hours, if at all. But it does not seem to us in the least degree more secure than Mr Hobbs' much simpler and cheaper contrivance of the moveable stump, or than some others which we have not yet described. And it is necessary to caution the public against *shop-window* locks in general, with large wagers set upon them; for unless you know that the lock exhibited in the window is the same as those usually sold in the shop at a moderate price, and unless the conditions of the challenge (which are generally "to be had within") are fair (we have seen some that were utterly unfair and absurd), the offer of "200 guineas to the artist who can pick this lock" does not prove that any other lock in the shop is worth 200 pence; and it is, in fact, nothing but a mere advertising trick.

Mr Parnell's other lock, sold by himself only, has the

Parnell's
Locks.

Parnell's
Lock.

advantage of being much cheaper, and at least as secure as the one with the self-acting lever and expanding key, which is the ordinary construction of the locks under his former patent. This lock has also the revolving curtain, and there is a small ring B (fig. 21) on the under side, which incloses a deep circular ward set in the back of the lock, which requires a very deep cut in the key, so that there would be very little room for a pick to play in. These two features are not claimed by Mr Parnell as novelties, and, in fact, they are old enough to be open to any body. The curtain has another ring near its edge, which just comes over a pin P in the uppermost tumbler when it is down, and prevents it from rising, except when the

Fig. 21.

curtain is turned far enough round to bring the gap at C in the ring over this pin, which happens just when the key begins to lift the tumblers. But the real peculiarity of the lock is this: In locking, just before the key leaves the tumblers, it delivers the stump, not into the place where it is now shown lying, but into the notch S; but before it leaves the lock the key encounters the end of a lever KL, which pushes the bolt back a little, and so lets the tumblers drop a little lower, with the stump in the position shown here. When the key opens the lock again, it passes by the end K of the lever, and first lifts the tumblers a little by their corners, near K, at the same time that the gap C in the curtain-ring comes over the pin P; then it encounters a piece that comes down from the bolt near T, and shoots the bolt forward a little, without which the tumblers cannot be fully raised (as will be seen from the shape of the false notches), and then the key operates as usual. Nevertheless, this certainly cannot be placed in the class of absolutely secure locks; for if a pick can be got to work over the neck-ward and curtain-ring or barrel, which is well known to be possible, it does not appear to us that there would be more difficulty in picking this lock than any other with false notches; for it makes no difference that the bolt has first to move forwards a little and then backwards, and the curtain could easily be got into the position to free the tumbler which it holds. However, these locks are sold a good deal cheaper than other locks with much less security used to be, and, if not absolutely secure, they are sufficiently so for all common purposes.

This reduction in the price of good locks, besides the improvement in the quality, is plainly the consequence of the exposure of the defects of all the existing English locks in the Great Exhibition, which some persons endeavoured to smother as dangerous, and others to explain away as proving nothing against the character of our locks. Not only have we got Mr Hobbs's own improvements in construction, and reduction in price, by the introduction of machinery for lock-making to an extent hitherto unknown, but there is now in the market a variety of what may be called very good locks, even though most of them could be picked by a very first-rate hand with plenty of time, and at lower prices than were charged for the only two locks which had any reputation until the last few years, viz., the Bramah and the Chubb locks. And the mere variety of locks is in itself a source of security, because a thief no longer knows by the look of a key-hole what kind of machinery he has got to deal with inside.

Restell's Lock.—There is only one other modification of

the old many-tumblered lock that we need notice, and that is Mr Restell's. The only peculiarity in it (for the revolving curtain and barrel are much too old to be so designated) is the addition of a disc at the bottom of the barrel, in the same plane as the bolt. The bolt can only pass when the disc is in one position, i.e., when a piece which is cut out of it is just under a kind of tooth in the bolt; and at all other times the disc, lying partly within the bolt, holds it fast, and prevents any pressure being put on the tumblers. But this, again, proceeds on the erroneous but common assumption that the instrument for feeling and lifting the tumblers a little at a time cannot be used when the key-hole is closed, except at the centre, by the curtain and barrel; whereas it is, in fact, worked through a kind of hollow key, which presses on the bolt while the pick works the tumblers, and it can be done in locks with far greater impediments to it than this, although we say of this, as of Mr Parnell's, that it is an improvement upon any of the locks made before 1851.

Restell's
Lock.

Locks without Tumbler-springs.—We now come to a class of locks in which the tumblers or slides are no longer moved one way by springs and the other way by the key; for we shall postpone the description of the complicated American changeable key locks until we have taken the reader through the easier matters. In the locks we are now going to describe the tumblers, or slides, or discs, which stop the bolt, are kept in their places by friction only, and will stand anywhere, having thin plates lying between them, and being pushed or turned one way in locking and the other way in unlocking.

In the Exhibition of 1851 there was a disc or wheel lock exhibited by an American named Jennings, who used to expound it with great eloquence as cheaper and better than any other lock in the world. It had also a changeable key, i.e., the key was a mere stalk or shank, fitted with small rings, each with a bit projecting from it, and they could be transposed, together with the corresponding parts in the lock. This of course can be done, and had been done before, with the key of any tumbler-lock, if you take the lock off and change the tumblers, provided the bits are made to fit into the key, instead of being part of it as usual; but we shall have to say more of this hereafter. We have been unable to learn what has become of Mr Jennings or his lock, except that Mr Hobbs showed us a very simple way of picking it, by poking a piece of watch-spring, with a hook at the end, between the discs, and feeling for the notch in the circumference, and then bringing it round to the right place for the lock to open.

Jennings's
lock.

Andrews's Lock.—Another American lock on the disc principle, by Dr Andrews, was exhibited at the Society of Arts in 1853, with some others that we shall notice, when that sagacious body awarded its premium to a lock made by a Mr Saxby, which Mr Hobbs forthwith picked in three minutes with a bit of wire, and then reminded them that he had himself exhibited a drawing of an old lock of the same

construction at a lecture in that very place only about a year before. Dr Andrews's is called the snail-wheel lock, because all the discs except the upper one have snail-shaped holes in them, as in the last of these figures (fig. 22). The upper disc has only a square hole (except that for the drill-pin on which they all turn), which is the key-hole, and that disc always

Fig. 22.

Andrews's
Lock.

travels with the key; the others only begin to move in one direction as soon as the key encounters the spiral edge of the hole, and of course they are carried to different distances, according as the corresponding bit of the key is shorter or longer. They are separated by loose, thin plates, which cannot turn with them, and act as friction plates. Each disc has a notch in it, and it is only when all these notches are brought together under the end of a spring lever, called a "toggle," that it can drop into them. As soon as you feel or hear that take place, you have to turn the key back again, and the discs still keep together, because the toggle fills up all the notches, until it is worked out, as they revolve, and it carries the bolt with it; and then the discs no longer move together, but some lag behind until the key reaches the square end of all the snail-holes, and so brings them all into the original position, with the notches standing in different places, and then the key can come out. We do not know by what method this lock can be picked, as it can hardly be possible to distinguish between the pressure of the toggle on the edges of the discs and the absence of pressure when it is over a notch, on account of the great amount of constant friction; and the smallness and eccentricity of the key-hole would make the watch-spring method extremely difficult, if not impracticable. But besides the key-hole being thick and clumsy, on account of the great friction which it has to overcome, the lock is uncomfortable to work, and it is therefore not likely to come into use against the easier locks with smaller keys, and equal, or at any rate sufficient security, which are now made.

Tucker's
locks.

Tucker's Locks.—There have been several locks on the disc principle invented in succession by Mr Tucker, of Fleet Street, the first two of which had revolving discs; and in the last and more simple one, patented in 1855, though the discs no longer revolve, they slide between fixed plates without springs, and do not turn on a pin like common tumblers, and will stand indifferently anywhere. It will be sufficient to describe the last of these inventions, as Mr Tucker himself states it to possess all the elements of security of the former ones, with the advantages of being much cheaper, because more simple in construction. In fig. 23, T T is one of the sliding tumblers, which are separated by thin fixed plates, and slide upon the guide-pins at T T, and have also friction-springs X, pressing on them to keep them steady. S is the bolt stump, which can only enter I, the gating of the tumblers, when they are pushed the proper distance towards the left, which the key will do as soon as it turns towards the left, in the usual way of unlocking. But something else still prevents the bolt from falling, and that is the flat curtain C, which turns with the key, and has also a barrel B, as in several of the other locks we have described. This curtain also prevents the stump from being pressed against the tumblers, being just big enough to keep it from touching them until it has turned nearly three-quarters round, when the pin S, which stands up on the stump, can enter the opening D in the curtain (shown by a dotted line in the drawing, to prevent confusion). But by the time the curtain has got so far round, any instru-

Fig. 23.

ment in the key-hole would be prevented by the barrel from reaching the tumblers so as to push them back and feel the pressure of the stump; at least so the inventor asserts, and we do not venture to contradict him; but it must be remembered that no revolving curtain and barrel have yet been able to prevent the instruments of the American lock-pickers from reaching and moving the tumblers, at the same time that the barrel is being pressed the other way in order to keep up pressure on the bolt. The only way (so far as we can see) to prevent this is by a contrivance, such as Mr Denison's lock (described below) was first made with, of a kind of door between the tumblers and the key-hole, which opens for the key just before it reaches them, and closes again after it has moved the tumblers, and before any action at all upon the bolt begins. It will be seen hereafter that in that lock this shutting off the tumblers from the key-hole was afterwards carried still further, as the key there does not operate on the bolt at all, but must be thrown out of the key-hole, and the hole completely closed, before the bolt can be drawn back; but the first arrangement may very well be used in cases where the key is wanted to operate on the bolt.

We have not yet explained how the bolt in this lock is drawn back when the curtain has got into the proper position for it. It is not done by the last bit in the key acting directly on the bolt, as usual, but by a bit P fixed on the curtain itself, which acts upon the notch B in the bolt, as the key usually does. And this same bit P performs another function in locking, viz., shooting all the tumblers into the position here shown by striking against a pin which is set in the bottom one, and comes up to the curtain, and so carries all the others with it by means of the square notch which is cut in all of them, except the one which has the pin in it. It must be observed that the curtain does not lie close upon the tumblers, but there is the thickness of the bolt, or of the bit P, between them. A spring locks into the curtain and prevents it from being turned, except when this spring is pressed down by putting a key into the key-hole. One object of making the curtain, and not the key, to lock and unlock the bolt is, that you guard against the risk of what is called short-locking; i.e., sending the bolt in any common tumbler-lock not quite far enough for the tumblers to drop. There are means by which a person intending afterwards to pick a lock might cause it to lock short, if he had previous access to it, or possession of the key, at least as locks are generally made, and then, of course, he has only to pull the bolt back, the tumblers having never fallen. Moreover this arrangement in Tucker's lock allows it to be locked by any key that will turn in the key-hole, though it cannot be unlocked by any but the true key, or one which will move all the tumblers to the right place for the stump to enter them. Mr Tucker has also applied the curtain in his padlocks in such a way that the shackle has a tail reaching inwards and resting against the curtain at all times, except when it is in the proper position for opening; i.e., when this tail is opposite to a segment cut out of the curtain corresponding to the opening D in the lock just now described, but much larger. The object of this is to obtain greater strength than usual to resist all attempts to force the shackle open. The cheapness of these locks is due to the circumstance that all the principal parts can be stamped out of sheet brass, the curtain alone being cast with the barrel and bit P on it, and its face turned, which is a cheaper operation than filing. In this respect it approaches to Mr Hobbs's style of lock-making, only he has carried the stamping and machine-finishing system much farther; indeed, it is hardly exaggerating to say that he has abolished the use of the file, and left nothing to hand labour except the mere fitting of the pieces together, and putting the tumblers in the right position to have the gating cut according to the key.

Tucker's
Locks.

Nettle-
fold's Bolt.

Nettlefold's Bolt.—We have just now alluded to padlocks, and we shall do so no farther, because they are generally of exactly the same internal construction as other locks of the same maker. And, for the same reason, it is unnecessary to describe the various modifications of the fastening part of locks to adapt them to peculiar uses or positions; but there is one which does seem to be worth a short notice, viz., an invention of Mr Nettlefold, patented in 1839, for making the bolt hook into the striking plate, against which it locks. This drawing of it (fig. 24) will explain the nature of the contrivance at once. We have inserted no tumblers, because it may be used with one kind of lock as well as another. It is convenient for writing-desks, sliding cupboards, and even for drawers, which can often be prized open by merely putting in a screw-driver above the lock, and forcing

Fig. 24.

up the piece over it just enough to let the bolt pass, which is generally short. There are other ways of doing the same thing, such as making the bolt itself hooked, and giving it two motions, first vertical, to shoot it out, and then horizontal, to hook it into the striking plate; and some Bramah locks are made with a kind of annular bolt, which forms a rim to the cylinder, with a segment cut off in one place to let the striking plate come down, which is then taken hold of by the other part of the ring as it revolves. Bramah locks of portfolios, and articles of that kind, are usually made in this way, which is very cheap and simple.

Master-
keys.

Master-Keys.—It is often convenient to have a set of locks so arranged that the key of one will open none of the others, and yet the owner of the whole may have one master-key that will open them all. In the old locks with fixed wards this was done by making the wards of a slightly different form, and yet such that one skeleton will pass them all, just as the skeleton-key in fig. 4 will serve for the warded key of fig. 3, and a multitude of others. In locks with sliders or tumblers, the way is to make one tumbler in each lock with a wider gating, so as not to require lifting so high as it does in the other locks of the set; then the key of that lock will raise that tumbler in that lock high enough to clear the stump, and yet the master-key, which has a longer bit in that place, will not raise it too high, because the gating is wide enough for both; but the special key of that lock will not open any other of the set which has not the same tumbler widened in the gating. Mr Chubb, some years ago, made a set of locks for the Westminster Bridewell, with keys for the different grades of officers. The owner of the head key can stop out any of the under keys; and if any attempt is made to pick any lock, and the detector is thrown, it cannot be released by any of the subordinate keys, though they can open the lock in its normal state, and consequently the governor must be acquainted with it. There are a variety of other forms of many-tumbled locks, some with the tumblers acting upwards at one end and downwards at the other (Parson's lock); and others with some of the tumblers pulled down by bits cut within the web of the key, besides the usual ones to be pushed up by the key (Somerford's); and some with a combination of the Bramah plan in the pipe of the key, with the Chubb plan in the bits, and so on; but none of them involve any novelty in principle, and they are all capable of being dealt with in the same way: and therefore we shall at once pass on to another class of locks, viz., those which shut of themselves, and are called—

Spring or Latch Locks.—These locks we chiefly notice because they require a particular provision to make them

in the smallest degree secure, and are, nevertheless, often left without it, by way of saving a shilling or two in their price, and multitudes of street-door robberies are committed in consequence. The former of these two names is generally used for a lock which shuts of itself on a box or drawer, or articles of that kind; and the latter for street or room-door locks, which shut of themselves, and open with a handle on the inside, but only with a key on the outside. In the simplest and cheapest form of these locks there is no pretence of any security except a few fixed wards, which the key has to pass; and, as before explained, that is no security at all against anybody with the smallest dexterity, and with a serious intention of opening the lock. Next to them, or rather below them, pretending to be what they are not, come the locks which lock a certain distance themselves by means of a spring, but can be locked farther by the key, and having tumblers, but no fixed wards (which a good tumbler-lock does not require). But though this kind of lock cannot be opened when it is thus double locked, except by the key, or some efficient mode of picking, yet when they are only self-locked (which is the most they are ever locked in 99 cases out of 100), the tumblers are of no more use than if they did not exist, and the lock can be opened by any bit of bent wire that will go into the key-hole. It should be remarked however, that the Bramah lock is just as secure as usual when used for a spring or latch lock, because the key cannot turn at all without pushing in the sliders properly. But in this, as in all latch-locks, it is very unsafe to have a handle which pulls back, as it can easily be reached by a wire put through a hole in the door; the handle should always be made to turn, like a common room-door handle.

There are two ways in which spring-locks with tumblers may be made as safe as the same lock with an ordinary bolt. One is to make a click or catch fall into the bolt when it is drawn back, and not to make the tumblers to fall when the bolt is drawn back: in the shutting of the door this catch is pushed back by some knob projecting for the purpose, and then the tumblers fall and hold it fast. But this will not do for a latch-lock which is intended to open by a handle on one side of the door. For that purpose the proper plan is that which is now adopted in all good latch-locks, not to let the key act directly on the bolt, which has no stump, but on a false bolt which lies on the top of the real one, and has the stump fixed in it. When the real bolt is shut by the spring it carries the false one with it, and that is then locked by the tumblers. But the real bolt can be pushed back by the door shutting, or pulled back by the handle, without moving the false bolt, though it cannot be reached through the key-hole. In buying a lock, the test of this is to see whether the stump moves as you push or pull the bolt back. If it does the lock is good for nothing, unless it is on the peculiar construction to be described immediately.

Chubb's Latch-Lock.—In order to prevent the bolt from being pushed back by a piece of wire poked in between the door and the staple into which it locks, Mr Chubb has made the following ingenious modification of the common latch-lock. In fig. 25 the bolt is drawn back by turning a handle H as usual, but the handle also raises all the tumblers like a key. But the back tumbler T is not set on a fixed pin as usual, but on a pin in the bolt, and so travels with it; and when it is drawn back far enough, i.e., about half way, the spring S falls in front of that tumbler at T, and so, when you leave hold of the handle again the bolt only goes about half way out, as far as B, the point to which its face is bevelled. But when you push the door to, the sloped corner of the bolt at R raises the spring S, and the tumbler T not being then held up by the handle, it falls and clears the spring, and so the bolt shoots the whole way out, and the other tumblers fall upon its stump, and it can only be

Latch-
Locks

Chubb's latch-lock. opened either by the key K or the handle H raising all the tumblers to the proper height.

Fig. 25.

To prevent confusion, we may observe that there is another lock called Chubb's *latch*, in which the bolt consists of a number of tumblers prolonged. But this is a very inferior article to the *latch-lock* just now described, or even to a latch-lock made in the second of the methods above mentioned. We understand the latch-lock is used extensively in prisons (of course without the handle), where it is not only desirable to avoid the necessity of having to lock the cell doors by a key, but also to provide against the ingenuity of the inmates in pushing back the bolt of a spring-lock. It has been suggested however, that this provision may be defeated by a prisoner, or any other thief not yet in prison, putting something into the bolt-hole which will prevent the bolt from shooting full out, and then the tumblers will not fall, and the bolt can be pushed back easily. A safer lock for this purpose is one which we shall describe presently, and which locks by merely turning the handle, but cannot be opened without the key.

Spring-curtain.

We may observe also with reference to these latch-locks for house doors, that they very soon get spoiled, at least so far as to impede their action, and render them unsafe, by the dirty atmosphere of a large town. This might easily be prevented by using a spring curtain like that which we shall describe in Mr Denison's smaller lock. If purchasers of locks would insist on having such an addition made, it could be done without increasing the cost by more than a shilling, and it would save its price many times over, by the length of time the lock would go without cleaning, and last without being spoilt. But unless purchasers insist upon having it, it is not likely that the lockmakers will volunteer such an improvement. The curtain should slide easily on the drill-pin and on another pin, just below the lower end of the key-hole, and be pressed up by a long thin spring acting upon it near the drill-pin. We suggested this some time ago to a celebrated London lockmaker, and he undertook to get it done. After some months he produced a lock, with a spring curtain certainly, but (with that peculiar ingenuity for baffling any new invention which English mechanics generally display) the curtain made to slide on two pins set at some distance on each side of the drill-pin, instead of a single pin below it; and the consequence of course was, that there being nothing like the web of the key to push the curtain down straight, it went rather obliquely, and generally jammed itself fast upon the pins, and then (as usual in such cases) was pronounced impracticable, and thrown aside; and all this with one of Mr Denison's small locks as a model to copy, in which the curtain slides up and down quite easily. It has since been done properly by Mr Hobbs; and there is plenty of room to add it to any existing lock which has a false bolt lying above the true bolt for the key to act on, as every good

latch-lock must have; for otherwise the tumblers are of no value whatever, as explained above. Safe Locks

Safe Locks with small Keys.—In all the locks we have yet mentioned, the bolt is acted on by the key, even though the key may not touch it; and the key must therefore be strong enough to move the bolt besides lifting the tumblers, or whatever is substituted for them; and this makes the key for a large lock too large and heavy to be conveniently carried in the pocket, and a bunch of such keys impossible. To get over this difficulty, most of the makers of iron safes have adopted the plan (we do not know by whom invented) of shooting a large bolt, or a number of bolts, by means of a handle, and then a small lock with a small key locks into one of them, and thus fastens them all. The security then depends upon the impregnability of the small lock against fraudulent picking or forcible evisceration. And it may be mentioned here that there are certain thieves' instruments, by which a force sufficient to tear open the inside of a lock can be inserted through a key-hole of the common size. This, however, is now defeated by cutting out a piece of the back plate, and then screwing it on again, with only a few small screws; and so that alone gives way under any bursting pressure, whether from the instrument called the jack-in-the-box, or from gunpowder, which is another of the thieves' methods for cutting the knot which they cannot untie. If the small lock, therefore, cannot be picked, or forced, this mode of locking the bolts of a large door is quite safe, and you have the advantage of a very powerful lock with nothing to carry in your pocket larger than a small desk key.

Denison's Lock.—A lock was invented however, in 1852, but not patented, which combines the advantages of large and strong works, with a key-hole so narrow, that no instrument strong enough to injure the lock could be got in, nor a reflector to observe the bellies of the tumblers; and the bolt is not only shot by turning the handle, but locked besides, without using any key at all. But it cannot be opened without the key; consequently, there is no occasion to entrust the keys to clerks, or other persons who may be left to close the boxes or doors, provided the owner, or some one confidential person, is there in the morning to open them. This lock enjoys the distinction of being the only one of English invention which is pronounced secure,—at least against any known method of picking,—by Messrs Hobbs and Tomlinson, in the treatise before referred to. It was invented by Mr E. B. Denison, Q.C., whose name has been frequently mentioned already in the article on Clocks; and the following is its construction:—

Fig. 26.

In fig. 26 are shown the tumblers T, turning on a pin at or near the middle of their length, so as to be nearly balanced, though in small locks this is unnecessary. Between every two adjacent tumblers, and between the bolt and the tumbler next to it, there is a thin steel plate, which occupies the position shown by the dotted lines PP. These plates have one edge lying against the upper side of the lock, so that they cannot turn at all on the tumbler-pin, which goes

Denison's
Lock.

through them quite loosely. One or two of the plates should be bent a little to make them act as friction springs on the tumblers when the cap of the lock is on, so that they will stand indifferently in any position. In the figure they are drawn all pressed down, so as to prevent the stump S from entering the gating, and this has been done by the long tail Y of the handle, which, it is easy to see, will raise the left end of the tumblers, and depress the right, after the fan-tailed piece X of the handle has shut the bolt. After the tumblers have been raised to the proper height by turning the key half round (where it may be stopped by the plates P, P), the stump can enter the gatings, and the bolt can be drawn back by the handle, the tail Y then doing nothing. So far as we have gone yet, the lock would possess no greater security than any other many-tumblers lock; but there is a steel curtain CC, which does not revolve as usual, but slides on two pins set in the back of the lock, and is pressed up against the front plate by two spiral springs, so as to close the key-hole completely, except when it is pressed in. From the back of the curtain there goes a kind

of square plug (shown in section at fig. 27), which can be pushed through a hole in the back plate, and has a notch in it just in the plane of the bolt, and the bolt itself has a corner there; so that when the curtain is up, the bolt can be drawn back through the notch in the curtain plug; but when the plug is pushed in ever so little, the bolt cannot be drawn back, because its corner cannot pass the curtain

plug; and in this position the stump cannot be made to touch the tumblers, except one of them, which is made a little longer than the rest (as shown at T in fig. 26), in order to keep the bolt steady. It is evident then, that as soon as you push in the curtain to admit any instrument whatever, the bolt is held fast, and it becomes impossible to put any pressure of the stump upon the tumblers; in other words, the tentative mode of picking is impossible. In small locks, the curtain has no plug, but merely works against the edge of a second stump of the bolt, which can only pass when the curtain is up, and it slides on the drill-pin and another pin below it.

The security of the lock is further increased by the addition of what may be called a detector DEG, as it does detect if the bolt has not been shot far enough by the person who locked it; and what is of more consequence, prevents it from being opened in that state. It turns on a hinge or pin at G, and is held up or down by a jumper-spring at E, as in Chubb's first detector. In fig. 26 it is shown as held down, or out of the way of the bolt; but as the handle turns back again and draws back the bolt, the pin below X raises the detector a little, and then the spring is ready to throw its tooth into the notch in the bolt as soon as it is shot only about half way; and in that state the bolt cannot be drawn back without turning the handle far enough for the fan-tail X to send the detector down again below the corner of the spring, and by doing that you will also have locked all the tumblers, and so made the lock fast until the key comes to open it. And it is to be observed, that the curtain cannot be pushed in until the bolt is fully shot, so that no exploration of the lock can take place while it is open, or even partially open. It may be arranged, if required, that the curtain could not be pushed in, not only until the bolt is shot, but until the tumblers are locked also, by adding a spring catch under the curtain, to be freed by one of the tumblers when it is fully locked.

The following, therefore, are the advantages of this lock:—

1. A very large lock, with all its parts strong, only requires a very small key, not weighing above a quarter of an ounce.
2. No key is required to lock it, and you cannot leave the key in the lock (a fruitful source of mischief), and yet it is free from the inconvenience of spring-locks, which sometimes

shut themselves when not intended; and moreover, a large spring-lock requires a large and strong key to open it. 3. It cannot get out of order from the usual causes of the tumblers sticking together, or tumbler-springs breaking, because there are none, and the tumblers do not touch each other, but the friction-plates between them. 4. The key-hole being always quite closed by the curtain, except while the key is in, the lock is protected from dirt and from the effects of a damp or smoky atmosphere, which injures other locks. 5. The smallness of the key-hole prevents the insertion of any instrument strong enough to force the lock, and also prevents inspection. 6. It is pronounced by the highest authority to be secure against any known mode of picking. 7. It requires no delicacy of construction or high finish in any of the parts; and the moving parts are few; in fact, the whole of them together are fewer than the number of springs alone in the great American lock which we shall next describe. 8. It is free from the incumbrance of a patent, the inventor being one of those who agree with the opinion of the Jury on Philosophical Instruments in the Great Exhibition, and with many of the first engineers and most scientific men, that "patents are a great obstruction to the progress of science," and waste, on the whole, more money than they gain for real inventors.

Notwithstanding these advantages, we cannot learn that any of the lockmakers have taken up the manufacture of this lock, all of them having a settled course of manufacture of their own articles, which they find they can sell sufficiently; and unless some large order should be given for this lock (as for a set of prison doors, for which it seems peculiarly adapted, with a master-key arrangement) it seems not likely to be adopted until some startling event makes the public open their eyes to the insecurity of the established forms of English locks which they have long believed in. We now proceed to describe what has been considered the great triumph of transatlantic skill, viz.:—

Day and Newell's Parautoptic Lock.—This formidable Day and Newell's name has nothing to do with the chief peculiarity of this lock, viz., the power of changing the key and the state of the lock without taking it off the door, which might have been indicated by an equally imposing title—*parallactic*. Parautoptic only means that it cannot be examined through the key-hole, which is not peculiar to this lock. In order to understand this complicated machine it will be better to consider the provisions for security against picking, and those relating to the changeability of the key, independently of each other, as they have nothing to do with each other, and either might be used without the other. The object of the changeable key is merely to provide against the risk of its falling into the hands of somebody who may have taken an impression, and made a false key from it:

Denison's
Lock.

Fig. 27.

Fig. 28.

a risk which is perhaps rather more likely to be increased than diminished by the great size of this key, and the dis-

Day and
Newell's
Lock.

position of people not to carry such a large instrument in their pockets more than they can help, and the probability of their not taking the trouble to unscrew the bits and change the form of the key every time they use it. Assuming then, for the present, the key not to be made with moveable bits, the security of the lock depends on the following points:—The stump *ss*, which for the present must be assumed to be attached to the bolt, does not act against the tumblers *TT*, which are raised by the key, and may be called the primary tumblers, but on a set of secondary ones *tt*, which are made to follow the primaries whenever they are raised by a set of springs under them, which are not strong enough to resist the primary tumbler-springs, but are strong enough to lift the secondaries when the pressure of the others is taken off. But even this does not fully represent the independence of the secondary tumblers, for each secondary tumbler *tt* really consists of two pieces, of which one is pushed up by the spring and lifts the other with it, which has the gating or jaws to receive the stump, but can rise without the carrying piece being lifted. The consequence is, that supposing pressure to be applied to the bolt so as to hold fast one (or more) of the secondary tumblers, it only holds the gating piece, and the corresponding primary tumbler remains as free to move up and down as if there were no pressure, and therefore the pressure cannot be felt. Moreover, there is a fixed wall in the lock between the key-hole and the secondary tumblers, so that it is impossible to reach them from the key-hole. All the tumblers move between parallel guides, instead of turning on pins as usual; and the primary ones are also separated by thin loose strips of iron, which prevent them from sticking together. The secondaries, however, would be the most likely to stick, as their springs are weaker; and as their action depends entirely on the springs, which are comparatively weak, we cannot help thinking there is some risk of their getting stuck together by rust forming between them, or by a drop of thickened oil, as sometimes happens in Chubb's, or any other spring tumbler-lock.

The primary tumblers are also prevented from being inspected through the key-hole by a curtain *cc*, which is not the ordinary flat curtain with a small barrel close to the key-pipe, but a large ring or barrel turning in a circular groove in both the lock-plates. Moreover, this curtain is not concentric with the key-hole; and therefore, although the bits of the key do not project beyond the curtain when it is put into the key-hole, yet by the time it has got nearly half round they project considerably, and raise the tumblers as if there were no curtain at all in the way. On the front edge of the curtain there is a broadish flange with a segment cut off at the top, and on that segment there lies another tumbler (covering the primary tumblers, and supposed to

Fig. 20.

be taken off in fig. 28, but shown in fig. 29); and any raising of this tumbler by turning the curtain, brings over the straight part of the key-hole (through which alone any inspection could be made) a revolving plate (fig. 30¹), which lies outside the front plate of the lock, by means of a pin *p*, which comes through the front plate, and works in a hole in the revolving plate. This revolving plate is called the detector plate, but with no good reason, for, like many other so-called detectors, it detects nothing, though it does present additional obstacles to opening the lock with anything except the right key. For, when the lock is locked, it has hold of a pin *q* in the bolt, which can only be freed by the plate revolving, and so closing all the key-hole, except the hole in the middle, which is occupied by the key. There is also a kind of spring-lever *ll*, which locks upwards into the bolt, and is also only freed by the tail *m* of the revolving plate as it moves to the left under the action of the key.

Fig. 30.

In spite of all these accumulated securities, one of these locks was lately picked in America by a totally unexpected method. There is no great difficulty in getting an instrument into the lock which will deposit a little printing-ink, or other black grease, on the bellies of the tumblers just over the key-hole. This was done a short time before the owner was going to lock the lock; and the effect of his doing so was to spread the ink along each of the tumblers just as far as the key happens to touch it. If you can get now another instrument, or succession of instruments, into the lock, which will take off the impressions made on the tumblers, or measure the length of them, you can make a key from it; and the great size of the key-hole enables this to be done by putting in a wooden key of this shape; the rounded surface allowing the black on the tumblers to mark its own length thereon. Mr Hobbs however has defeated this contrivance, by adding a wiper to the revolving curtain, which always passes over all the tumblers after the key, and so wipes the ink along them all equally, and prevents the length of sweep of the key-bits from being distinguished. We may observe here, that the opening of a six-tumbled Newell's lock in this country, a few years ago, which the English lock-makers made a great deal of, proved nothing at all, as it was done by merely working through the permutations of the key, which are only 720 for 6 tumblers; and the right one was, by good luck, hit upon long before they were all gone through. An expensive lock of this kind ought not to have less than 8 tumblers, which would give 40,320 changes, and take a man four months to work through, at the rate of one every two minutes for twelve hours a-day. Besides that, it is possible still further to increase the number of changes by having some spare bits to the key beyond the number of tumblers, so that the number of changes may be increased enormously, as nobody finding (say) 12 bits loose could tell which eight of them had been used to form the key to lock the lock.

In order to understand the principle of this changeable key machinery, suppose that you could shift the position of the stump in an ordinary tumbler-lock, then all the bits of

Day and
Newell's
Lock.

Fig. 31.

¹ In this figure, which is copied from Mr Hobbs's *Rudimentary Treatise on Locks*, the detector plate is drawn the reverse way of the two figures of the lock; for what reason we are not aware.

Day and
Newell's
Lock.

the key would require making shorter or longer in order to raise the tumblers to the proper height. Suppose next that each tumbler had a stump of its own screwed to the bolt, but capable of being unscrewed and shifted at pleasure, then every bit of the key would require altering whenever you alter the position of the corresponding stump. And again, suppose these separate stumps to be so attached to the bolt, by a ratchet and click, or some similar contrivance, that when the bolt is back and the stumps lying in the jaws of the tumblers, the tumblers will carry the stumps with them to whatever height they may be raised by a key, and leave them sticking to the bolt at that height when the bolt is shot, and the stumps pass out of the jaws of the tumblers,—then it is clear that the lock can only be opened by the same key which raised the tumblers and stumps to that particular height; and yet, as soon as it is opened, the stumps again come under the dominion of the tumblers, and any other key will do to lock the lock again just as well as the one which was used before. In other words, such a lock is perfectly neutral and indifferent as to the key which may be used to lock it, but it cannot be unlocked by any key except the one which locked it last; and, therefore, by changing the key, or the arrangement of a given set of bits fixed to one stem, you change the lock also.

We may observe, that a key with transposable bits is by no means new; but then it always before required the lock to be taken off, or the tumblers transposed by some other operation, to suit the alteration of the key. Fig. 32 shows the construction of any changeable key, the bits being put in in any order, and fastened by a screw going through them all.

Fig. 32.

Now, to apply this to Newell's lock. In fig. 28 it is shown unlocked, and the moveable stumps *ss* are then lying within the jaws of the secondary tumblers *tt*; and besides that, they are now taken hold of near the top by the long pieces projecting from the primary tumblers *TT*. Consequently, when the primaries are raised by the key for locking, the sliding stumps *ss* are lifted with them; and as they slide up and down between guides fixed to the bolt, they are carried forwards, and out of connexion with the primary tumblers when the bolt is shot; but just before the connexion ceases, a click *k* falls into the back of the stumps (which are notched for the purpose), and holds them at the same height until they return. There are as many notches in the stumps as there are different lengths in the key-bits; and, as before stated, there may be any number of bits capable of fitting on to the same key, whether of the same or different lengths, so as to increase the variations in the lock without increasing the number of the tumblers.

These locks do not appear to have been as yet much adopted in England: whether from the cost, the ponderousness of the key, and the trouble involved in taking it to pieces frequently (for without that, the changeability is no security whatever), or merely from the national antipathy to novelties, and the national confidence in our own security, we do not pretend to say. It is certain that, in America, both the thieves are more dexterous, and the owners of property spend much more upon locks and safes than we do. A New York watchmaker told us lately that he locks up all his valuable goods every night in a cast and wrought iron safe two inches thick, with a lock that cost £50. There are however some of them used in the Bank of England, and a few other banks.

The French Changeable-key Lock, though very inferior to the American ones in security, has this advantage, that nobody can lock or change it for mischievous or fraudulent purposes without possession of the key that last locked it. The primary tumblers which are raised by the key do not

contain the gatings for the stump, but work a second set of tumblers which do, by means of teeth, like two toothed wheels working together. In order to change the lock, you overlock it backwards a little with the key that will open it (*i.e.*, which locked it last), and, by turning a small handle, you throw the two sets of tumblers out of gear with each other. Then change the bits of the key as you please, and put it into the lock again and turn it, as before, half way round, and bring the tumblers together again by the handle. They will join by a different set of teeth from before, and the altered key alone will open the lock. This plan may be adapted to any kind of tumbler-lock; and if it is one of a secure construction, it would be just as good as the more complicated American lock. Mr Chubb has lately made some of these locks; but in this instance also, the necessary size and weight of the key seems to be an impediment to their use; and probably any one who was inclined to spend a largish sum on a changeable lock, would buy the American one, which is undoubtedly very superior to the French in security both against picking and violence.

In order to get over this disadvantage of a large key, Mr Hobbs invented another lock, which is equally changeable, and still more parautoptic, or secure from inspection, than Newell's. The key that you have to carry is, in fact, nothing but the web or bits of a key, which may be either fixed or changeable, according to the nature of the lock. The key-hole has no centre of motion within it; but when this web of key is pushed into a hole in the lock, you turn a handle in another place, and that carries the key round quite invisibly, closing the hole completely; and as it turns, it opens the lock in the usual way, and returns. There is no possibility of feeling or examining its action, as no handle can go with it into the lock. The only objection to it is, that it is troublesome to put such a key in, and still more so to get it out again; and consequently, it has not taken with the public, nor do we believe that any lock will, which does not admit of a moderate-sized key of the usual form, and to be used with no more trouble than usual. We cannot help thinking that some spring action might be contrived, which would enable this very neat and small key to be pushed into the lock and shot out again, with no more trouble than is involved in turning a key and then a handle, as in the now common arrangement for large safe locks.

In fact, after we had written this, Mr Hobbs sent us a Yale's lock. new American lock, invented by Mr Linus Yale of Philadelphia, in which this very thing is done; the bits of the key being taken off the shank or handle, and carried away into the inside of the lock, where they perform their work, and rejoin the key shank before the revolution is completed. But the key itself is so large and thick, that it is far from realizing the advantages just now suggested in Mr Hobbs' travelling key-bits. The description sent with it is unfortunately quite unintelligible without an inspection of the lock itself, and the lock is so complicated, that we despair of being able to convey any idea of more than the general principles of its construction. It is a changeable lock, like Newell's, and with this great point of superiority over that lock, that it is entirely independent of the action of tumbler-springs; the moveable stumps, and the sliders or tumblers which act upon them, all lying between friction plates, as in Denison's and Tucker's locks, and standing indifferently anywhere. The only spring is a long spiral spring in the shank of the key (fig. 33), which drives a pin through the bits (which are all screwed together just in whatever order you please), and that pin yields to another pin in the lock, which meets it as you push the key in; so that the bits then become attached to this lock pin, which itself moves on a sliding stud, which carries off the bits into the acting part of the lock against the ends of

French
Changeable
Locks.

Fig. 33.

LOCK.

Yale's
Lock.

the sliding tumblers. This part of the lock, viz., the box containing the sliders, is shown in fig. 34. Any of the primary sliders T, when pushed by the key, carries along

Fig. 34.

with it the corresponding stump-slider S, and these sliders correspond to what we called the stump-tumblers in Newell's lock. After that is done, the box BB, which contains those sliders, is moved upwards, and delivers them all to the tooth Q, which holds them in whichever of their notches it happens to receive them. The primary sliders having been brought back by other motions in the lock to their original or neutral position, the box BB cannot be brought down again until all the primary sliders are pushed by the proper key into exactly the same position as they were when they parted with the stump-sliders. This part of the lock is really very simple, and involves no delicate or difficult work, as all the tumblers, all the stump-sliders, and all the little plates which lie between them both are, or ought to be, exactly alike, and may be stamped out of sheet-iron and brass; and the whole thing goes into a very small compass, although the lock itself is very large. We may observe here, that if you were to take the key out of the lock (filing off the small bit like that in the Bramah key, which goes under the cap to keep it in), after the bits are cut off and carried away into the lock, you would not find the key-hole open, but closed at the depth which takes in the bits by a hard steel plate, which slides over it as soon as the box or "carriage" of the tumblers begins to move.

It would be natural to suppose that the cross piece BB at the end of the slider-box is the bolt, as it is prevented from moving down as a bolt usually is, until the stumps can enter the jaws of the tumblers; and this cross piece is, in fact, lifted by a kind of talon turned by the key, just like an ordinary bolt. But, nevertheless, it is not the bolt, but merely locks into the bolt, or rather lifts a lever which does, so that no amount of force which could be brought to bear on the bolt has any tendency to crush the tumblers or sliders; and this is the reason why they can be so small while the lock is very large. The key however cannot be said to be small, for it is even thicker than Newell's; but you might carry only the bits in your pocket, and stick them on to the handle or shank of the key, which may be left anywhere near the lock. Another singular provision is introduced in this lock. The bolt or bolts are not square-cornered as usual, but large round cylinders, case-hardened, so that if you attempt to cut them with a saw they will only roll under it. Figure 35, which is copied from a paper called

the *Scientific American*, shows the general aspect of the lock when the front plate is taken off. All that box marked bb, which is as large as an ordinary lock, moves to the left,

Yale's
Lock.

Fig. 35.

and carries the bolts with it when the lock is locked, leaving, of course, some of its parts behind under the key-hole. The piece here marked *ii* is that which we called BB in fig. 34, and it works the lever *b*, which butts against the horizontal piece lying under the tooth-wheel *f*, when the lock-carriage is shot out. It will be understood perhaps by those who are conversant with machinery, how the different parts of this carriage, and the plates which cover it, may be carried backwards and forwards by the toothed wheels and pins shown in this figure; but, as we are convinced that any attempt to explain the details of this machinery, without having the lock itself before you, would be useless, we shall content ourselves with the attempt we have made to give some idea of the general principles of its action. We will only add, that the casting of both these American locks (which have all their heavy parts of cast-iron) is vastly superior to any iron casting we have ever seen made in England; and, on the whole, the United States are evidently far ahead of us in the manufacture of both good and cheap locks; and all because our people are too stupid to substitute machinery for hand-work, and because (as Mr Hobbs said in the discussion at the Society of Arts, on the establishment lately set up by the government for the manufacture of arms at Woolwich), "if the English workmen can do anything to make a machine go wrong, they will; whereas in America they will do all they can to help it." In the same way the American and French manufacturers of clocks have driven our makers both of common clocks and of ornamental clocks out of our own market; and any enterprising manufacturer might very soon finish the business by making both church and house clocks at half the price which is paid for the old-fashioned hand-work of Clerkenwell, and of far better quality.

(E. B. D.)

Locke.

LOCKE, JOHN, whose opinions have been fully discussed, and whose biography has been partly anticipated in the FIRST PRELIMINARY DISSERTATION, was born at Wrington, near Bristol, 29th August 1632. His father had served as a captain under Colonel Popham, in the parliamentary army; and the moderate inheritance of the family had suffered considerably during the civil wars. The young philosopher was the elder of two sons, and received his education at Westminster School, whence (in 1651) he was sent to Christ Church College in Oxford. Here he applied himself diligently to the study of the classics, and made rapid progress in the scholastic philosophy as it was then taught. In after life, however, and probably even before he had quitted the walls of the university, he learned to despise and regret this futile training, and he is said to have frankly acknowledged to Le Clerc, that he learned the first steps in philosophy from one to whom he afterwards proved a worthy antagonist—Descartes. In his reply to Stillingfleet, Locke ascribes to that “justly admired gentleman the great obligation of his first deliverance from the unintelligible way of talking of the philosophy in use in the schools of his time.” After he had taken his degrees in arts, Locke devoted himself to the study of medicine; and, although he neither graduated nor practised, his scientific accuracy procured him a high encomium from Dr Sydenham, in his *Treatise on Acute Diseases*; and his practical skill introduced him to the notice of the first Earl of Shaftesbury, “the false Achitophel” of Dryden’s satire, with whom he continued in undivided friendship to the end. In 1660 Locke wrote a tract on *Church Establishments*, recommending concessions on trivial matters alike to the government, whom he regarded as the friends of liberty, and to the opposition, whom he deemed factious and turbulent demagogues. Finding, however, very soon that he had mistaken the true characters of both parties, his love of truth compelled him to suppress the work and to bury all its misaimed eloquence and indignation. Lord King has preserved some extracts from it, which are valuable as giving us the starting-point of Locke’s opinions. In 1664 Locke visited Berlin as secretary to Sir Walter Vane, envoy from Charles II. to the Elector of Brandenburg, and in the following year he returned to Oxford. Preferment was offered him in the Irish Church, as well as diplomatic employment in Spain or Germany, but both proposals he rejected firmly, hinting in regard to the former, that it was to him an ungrateful stretch of power, to offer “an office of that nature to one who had given no proof of himself, and had never even tried the pulpit.” A more congenial home was provided for him, in 1666, by Ashley Cooper, afterwards Earl of Shaftesbury, who, profiting by his medical skill, invited him to his house, and soon drew him from the peaceful retirement of Oxford to the brilliant circles of the capital. It was by this nobleman that he was introduced to the Duke of Buckingham, the Earl of Northumberland, the Earl of Halifax, and many of the most distinguished men of the period. In 1688 he accompanied the Earl of Northumberland to France; but, on the death of the earl, returned immediately to England to superintend the education of Lord Ashley’s eldest son. So remarkable was the confidence which this nobleman placed in the prudence of the philosopher, that he requested him to choose a wife for his son, a delicate task which he very successfully accomplished. The fruit of this marriage was the third Earl of Shaftesbury, the genial and generous author of the *Characteristics*.

The first sketch of Locke’s work on the *Human Understanding* was made in 1670. He was present one day at a very animated discussion conducted by some learned men at Oxford. He listened attentively to everything that was said, and had the sagacity to perceive that it was after all only a dispute about words. This reflection was the germ of his immortal work. When Lord Ashley ob-

tained an earldom, and was appointed chancellor of the exchequer in 1672, he requested Locke to frame a constitution for the government of Carolina, which Charles II. had gifted to him along with seven other noblemen about nine years before. In the same year Locke obtained the appointment of secretary for the presentation of benefices; and in 1673, when his patron resigned the Great Seal, he became secretary to the Board of Trade. In 1675 Locke visited France for the benefit of his health, and resided at Montpellier, where he acquired the friendship of Mr Herbert (afterwards Earl of Pembroke), to whom he dedicated his *Essay concerning Human Understanding*. Removing soon after to Paris, he was welcomed by the most eminent scientific and literary men. During the whole of his residence abroad, Locke kept a journal of his observations, the pith of which have been preserved in his biography by Lord King. In these he gives the most admirable descriptions of the strange scenes in which he was placed; and in the excitement of new forms of life, the dry logical humour of the philosopher often gives way to a fine pleasantry, not unminged with pathos. The frightful pressure of taxation on the poor of France fills many pages in his journal; and his remarks on homely things are relieved by a dissertation on study, remarks on the immortality of the soul, and an essay on religion, in which he anticipates Tillotson’s argument against the real presence.

In 1679, when the Earl of Shaftesbury had regained his political power, Locke returned to England; but very soon that nobleman was again disgraced, charged with high treason, and compelled to retire to Holland in 1682, whither Locke faithfully followed him. Shaftesbury died in 1683, and his political enemies transferred their hostility to the exiled philosopher. Even at that distance from England he was pursued by the rancour of the government; the English envoy demanded Locke and some other gentlemen from the States-General, on the charge of being concerned in the rebellion of Monmouth. His friends, however, succeeded in keeping him out of sight till concealment was no longer necessary. At Amsterdam he met Limborch, Le Clerc, and other distinguished men, who formed themselves into a philosophical society, and held a weekly meeting for the discussion of interesting questions. At this time Locke was removed from his studentship in Christ Church College by an illegal order of the king; but nothing can be more honourable to his character than the testimony borne to his worth by Bishop Fell, the time-serving tool employed by the king to compass the ruin of his subject. The bishop freely confesses that, “although very frequently, both in public and in private, discourses have been purposely introduced to the disparagement of his master, the Earl of Shaftesbury, his party and designs, he could never be provoked to take any notice, or discover in word or look the least concern.”

In 1686 he published, in one of the *Bibliothèques* of his friend Le Clerc, his *New Method of a Common-place Book*; and in 1687 he abridged his *Essay concerning Human Understanding*, which Le Clerc translated into French, and gave to the world through the same channel. In the *Bibliothèque* of 1688, his first letter to Limborch *On Toleration* appeared; it was published in England in the same year; and it was translated into Latin, and published at Gouda, in 1689. Some theologians at Oxford, who disliked the freedom of the opinions expressed in the essay, attacked them, and Locke defended his work in three additional letters. Some of Locke’s friends were anxious to have him restored in safety to his country. The celebrated William Penn told him that he could get a pardon for him from the king; but being conscious of no crime, Locke declined to accept any pardon. The Earl of Pembroke also assured the king that the stories in circulation about Locke were false, and eventually obtained permission for his return to England. In 1688, he returned to his native country in the same fleet

Locke.

Lockhart.

which brought over the Princess of Orange; and Lord Mordaunt, who had offered him a diplomatic situation, which was modestly declined, succeeded in procuring for him the office of commissioner of appeals. Locke petitioned the king for the recovery of his rights as a student of Christ Church College, but without success.

His most remarkable work, the *Essay concerning Human Understanding*, was first published in England in 1690. Four editions appeared within ten years, and through the medium of Latin and French the author soon acquired a European reputation. Two *Treatises on Civil Government* appeared in 1690, written in support of the principles of the Revolution—the second being a reply to Jonas Proast of Oxford; and in 1693 he published his *Thoughts concerning Education*. He lived during the greater part of the rest of his life in the house of his friend Sir Francis Masham, at Oates; and it is interesting to know that Lady Masham (the daughter of his friend, Dr Cudworth) taught her only son according to the principles laid down in Locke's work on Education. In 1695 he wrote his treatise on *The Reasonableness of Christianity*, which, when attacked by Dr Edwards, was followed up by two *Vindications*. Besides his excellent tract on *The Conduct of the Understanding*, Locke, in his declining years, wrote many other works, chiefly religious, among which may be mentioned his *Discourse on Miracles*; *Paraphrases, with Notes, of the Epistles of St Paul*; an *Essay for the Understanding of St Paul's Epistles, by consulting St Paul himself*; and an *Examination of Father Malebranche's Opinion of Seeing all things in God*. About this time began his friendship with Newton, whose morbid misappreciation of Locke's philosophy and character led to a most affecting correspondence, which is given by Dugald Stewart in his *Dissertation*.

In 1700 Locke's health became so much impaired by his asthmatic complaint, that he objected to receive the emoluments of an office which he was no longer able to fill, and consequently resigned his situation at the Board of Trade. The king himself offered him a still higher position, but this also was declined; and although his public services fully entitled him to receive a pension, he could not be prevailed upon to accept one. Towards the close of his days he took great delight in the study of the Holy Scriptures; and all the finer qualities of his character came out into stronger relief as he approached the confines of another world. On the day before his death he expressed his gratitude to God for the happy life which he had spent. He told his affectionate friend, Lady Masham, that he had now come to the end of his career, and that he would not probably live till the next morning; but when she desired to sit up with him during the night, he begged that she would not do so, and that he would send for her if any change should occur. On the following morning, while Lady Masham was engaged in reading the Psalms to him, he requested her to stop, and in a few minutes expired, on the 28th of October 1704, in the seventy-third year of his age. He was buried in the tomb of the Masham family, in High Laver Church. The best edition of his works is in 10 vols. 8vo, London, 1801 to 1812. (See Lord King's *Life of Locke*, and Dugald Stewart's *Preliminary Dissertation*.)

LOCKHART, JOHN GIBSON, a critical and miscellaneous writer of considerable power and celebrity, was born in the manse or parsonage of Cambusnethan, county of Lanark, in the year 1794. He was the first son by the second marriage of the Rev. John Lockhart, minister of Cambusnethan, with Elizabeth Gibson, daughter of the Rev. Mr Gibson, minister of St Cuthbert's, Edinburgh. The father of Mr Lockhart was afterwards appointed to the College Church, Glasgow, and in this city John received his first education. He distinguished himself at college, and obtained one of the valuable bursaries (worth about £150 per annum) known as Snell's Exhibitions, in virtue

Lockhart.

of which he proceeded to Balliol College, Oxford. He retired from the university with the degree of LL.B., and applied himself to the study of Scottish law. He was called to the bar in 1816, but soon found that he was not calculated to excel as an advocate. He was more attached to literature than to law, and nature had denied him the fluency and self-possession necessary for success in addressing a court or jury. His contemporaries saw with surprise and pain the accomplished, handsome, carefully-dressed advocate, who had been engaged in *quizzing* his associates around the court table, or in drawing clever caricature sketches with his pen, rise up in trepidation to "state a case,"—how he hammered out a few words, got confused, plunged deeper at every step, and at length, fairly losing himself, sat down in an agony of vexation. A more congenial field was opened up by the establishment of *Blackwood's Magazine* in 1817, and for a period of seven or eight years there were few numbers of that periodical which did not contain some pungent or graceful article from the pen of Mr Lockhart. He tried all styles and subjects; he translated from the German and Spanish, reviewed books, indited bitter political articles, full of Oxford Toryism and scholarship, against all Whigs and Cockneys; and no one excelled him either in cold and stinging sarcasm, or in slashing invective. He also sketched scenes and characters with a milder hand, and composed occasional copies of verses, some of which breathed the inspiration of genuine poetry. His position in society was benefited by his marriage, 29th April 1820, with the eldest daughter of Sir Walter Scott. Previous to this Mr Lockhart had, in conjunction with his friend Mr (afterwards Professor) Wilson, written *Peter's Letters to his Kinsfolk*, 3 volumes—a lively but exaggerated picture of Scottish society, character, and manners, including portraits of Scott, Jeffrey, Chalmers, &c. In 1821 appeared his novel of *Valerius*, an exquisite Roman story; in 1822, *Adam Blair*, a Scottish tale of domestic life, containing some powerful painting of the passions; in 1823, a longer novel in 3 volumes, *Reginald Dalton*, delineating English and especially university life; also a translation of *Ancient Spanish Ballads*, remarkable for elegance of style and versification; and, in 1824, another novel in one volume, somewhat in the style of Godwin, entitled *Matthew Wald*. In 1825 Mr Lockhart succeeded to the editorship of the *Quarterly Review*, which he continued to conduct till within a short period of his death. His other works were,—a *Life of Burns*, written for Constable's Miscellany, and published in 1828; a *Life of Napoleon*, contributed to Murray's Family Library; and, in 1836, his *magnum opus*, the *Life of Sir Walter Scott*, which, as originally published, extended to 7 volumes 8vo. This was a work of great difficulty and delicacy. He had to fill a broad canvas with living or recent characters, and with contemporary events. He had to enter a critical arena preoccupied by the greatest names of the age, and to deal with affairs of active life and business, as well as with matters of intellect and imagination. He aimed at strict impartiality; and we have seen a private letter from him, in which he declared that he wrote as if the spirit of Scott, intent only upon truth, looked down upon him at the moment of composition. The alloy of human error, however, could not be absent, and some grave and serious blemishes stained the work. In relating Scott's business transactions, not only was too great prominence given to them, but manifest injustice was done to the Ballantynes, the early associates and friends of the illustrious novelist. Wanton offence and needless pain were also given to other parties by partial and incorrect statements, which no doubt sprung from the author's desire to bring out Scott in bold relief, and to impart variety and vivacity to the memoir. The work, however, is really a great one. We recognise in it Lockhart's manly and independent tone of description, his

Lockerby
||
Locle, Le.

true and penetrating estimate of life and conduct, and the masterly powers of description and analysis which he brought to his task. As a mere literary work, in style and treatment, it must rank in the first class; and as a biography, for fulness and interest, it is only surpassed by Boswell's *Life of Johnson*. Mr Lockhart's *Life of Burns* is an able little work, full of fine moral and picturesque delineation. In the *Quarterly Review* he seemed also to select biography as his chosen field. His critical sketches of Theodore Hook, Campbell, Southey, &c., display the same characteristics as his elaborate works,—the quick eye and firm hand, that never hesitated to use the scalpel freely lest too deep a wound might be inflicted, are visible in the slightest of these dissections of character and conduct. Mr Lockhart's tact and management were no less manifest in the general variety and attractive character of the *Review* while it was under his charge. We meddle not with its political disquisitions, which were often narrow and bitter enough; but he unquestionably made this powerful organ of a party keep pace not only with the literature, the science, and discovery of the age, but with its social tastes, amusements, and fashion. In 1843 Sir Robert Peel rewarded Mr Lockhart with the sinecure appointment of auditor of the duchy of Cornwall, worth L.400 per annum.

The latter years of Mr Lockhart's life were not happy or genial. He had survived his wife and all the other children of Sir Walter Scott. His own family consisted of two sons and a daughter; both his sons predeceased him, but his daughter (married to Mr Hope Scott of Abbotsford) still lives to continue the illustrious line of Scott. Irregular health and study impaired Lockhart's strength, and induced habits of indolence, while his literary ardour was still strong within him, and flashed out at intervals. As he said of Campbell, "A high and supereminent prize seemed still within his reach, but this spur was overmastered by the chill of tremor and the creeping of laziness." He endeavoured, by a winter in Italy, to renovate his shattered constitution, and at first the result was favourable. He returned somewhat invigorated, though feeling acutely that premature old age had set in. He had intended never again to visit Abbotsford after Scott's death; but, in the desolation of his last days, when his spirit was broken and health had utterly fled, he turned to it once more, and his parting spirit was soothed by the attentions of filial duty and tenderness amidst those scenes, immortalized by genius, which had witnessed his youthful ambition and happiness. He died at Abbotsford on the 25th November 1854, having shortly before completed his sixtieth year. (R. C.—S.)

LOCKERBY, a market-town of Scotland, in Dumfriesshire, on the Caledonian Railroad, 13 miles E.N.E. of Dumfries. A considerable trade in pork is carried on; and the largest lamb fair in Scotland is held here annually in August. Market-day, Thursday. Pop. (1851) 1569.

LOCKPORT, a town of the United States of North America, capital of Niagara county, New York, on the Erie Canal, which here descends to the Genesee level by means of ten double combined locks, 23 miles E.N.E. of Niagara Falls by railway. The town contains churches belonging to all the principal denominations, and is plentifully supplied with educational establishments. The main cause of the prosperity of Lockport is the vast water-power it derives from the locks on the Erie Canal, providing its numerous flour, saw, and other mills with abundant motive power. Among the principal of its manufactures are wool, cotton, and iron. A large trade is also carried on with Buffalo, Rochester, and other places by means of the canal. Pop. (1852) about 14,000.

LOCLE, Le, a large scattered village of Switzerland, canton of Neuchâtel, on the Bied, which here disappears in the chasm of a neighbouring rock, 10 miles W.N.W. of Neuchâtel, and 3 miles E. of the French frontier. Its inhabit-

Locri
||
Locris.

ants are chiefly employed in clock, watch, and lace making, and the manufacture of trinkets. Not far from the town is a tunnel, 950 feet long, which was excavated in 1806 for the purpose of relieving the valley of the superabundant water occasioned by the melted snow in spring. Pop. 8514.

LOCRI, or LOCRI EPIZEPHYRII, a town of the Greek Locrians in Italy, on the S.E. coast of the Bruttian peninsula. Ephorus ascribes its foundation to the Locri Opuntii; Strabo to the Locri Ozolæ. The former opinion is the more prevalent among ancient writers. The name Locri Epizephyrii favours Strabo's supposition that this settlement was the offshoot of a Locrian settlement at Cape Zephyrium (Capo di Bruzzano). The date of its foundation is uncertain. No less obscurity involves the early history of the Locri until about B.C. 660, when their famous lawgiver, Zaleucus, published his code of laws, supposed to be the earliest written legislative system ever given to any Grecian state. So enduring was the beneficial effect of these institutes, that even in the time of Demosthenes, Locri is cited as an ensample of good government. The next important event in its history is the battle at the River Sagras, in which 10,000 Locrians and a few Rhegian auxiliaries defeated, with great carnage, an army of 130,000 Crotoniats. From a very early period of their history the Locrians were bound by a firm alliance to the Greek city of Syracuse. Nor did their fidelity to that state cease until its tyrant, Dionysius the Younger, took refuge in their city, seized upon their citadel, cruelly oppressed them, and was finally expelled. They were allies of the Romans against Pyrrhus; but after the battle of Cannæ, in 216 B.C., revolted to the Carthaginians, and did not resume the yoke of Rome until 205 B.C. From this period Locri seems to have gradually declined in importance; and after the sixth century, there is no note in any author of its existence. About 5 miles from the modern city Gerace, travellers have discovered its site, containing, among other remains, the fragments of a Doric edifice, supposed to be the temple of Proserpine. Among the celebrated natives of Locri were the poets Erasippus and Xenocritus; the philosophers Acron, Echecrates, and Timæus, said to have been the instructors of Plato in Pythagoreanism; the citharaplayer Eunomus; and the famous boxer Euthymus.

LOCRI, the country of the three Grecian tribes, the Locri Ozolæ, the Locri Epicnemidii, and the Locri Opuntii, is supposed by Niebuhr to have extended originally from the Corinthian Gulf on the W., to the Eubæan Sea on the E., until broken up into two parts by the immigration of the Dorians and Phocians. The Locrians thus became two distinct tribes, differing in manners and civilization, and separated by Doris and Phocis. The eastern tribe, the Locri Epicnemidii and Opuntii, were the more civilized; the western, the Locri Ozolæ, are represented by Thucydides as semi-barbarians even at the time of the Peloponnesian war.

The territory of the *Locri Epicnemidii* and *Opuntii* extended along the shore of the Eubæan Sea, from the pass of Thermopylæ to the mouth of the River Cephissus, and was divided into two parts by a narrow slip of Phocis that runs down to the sea-coast. The southern part was inhabited by the Opuntii, so called from Opus, their chief city. The Epicnemidii held the northern part, and derived their name from Mount Cnemis, the boundary between their country and Bœotia. The towns of the Opuntii were,—Alope, Cynus, Opus, Halæ, Larymna, Calliarus, Naryx, and Corseia; those of the Epicnemidii were,—Alpenus, Nicæa, Scarphe, Thronium, Cnemis, Tarphe (afterwards Pharygæ), and Augeiæ. Homer mentions the eastern Locrians as following Ajax, the son of Oileus, to the Trojan war with forty ships. In the Persian war the Opuntii fought on the side of Leonidas at Thermopylæ, and sent their contingent of seven ships to the Grecian

Lodève
||
Lodi.

fleet. They also joined the Epicnemidii in an alliance with Sparta during the Peloponnesian war.

Locri Ozolæ occupied a district on the Corinthian Gulf, bounded on the E. by Phocis, on the N. by Doris and Ætolia, and on the W. by Ætolia. The origin of their name is uncertain. Different authors severally derive it from the smell (ὀζή) emitted by the sulphur-springs at the foot of Mount Taphiassus, from the fragrance of the asphodel that abounded in the country, and from the undressed skins (ὀζαι) worn by the primitive inhabitants. The Locrians themselves traced it to the branches (ὀζοι) of a vine peculiar to that district. The country is rendered mountainous by off-sets from Mount Parnassus in Phocis, and from Mount Corax in Ætolia. The only river worthy of note is the Hylæthus (Morno). Amphissa, lying near the borders of Phocis, was the most important town of the Ozolæ. The other towns were, — Molycreia, Naupactus, Ceneon, Anticyra, Eupalium, Erythræ, Tolophon, Hesus, Ceanthe, Ipnus, Chalæum, Ægitiium, Hyle, Crocyleium, Messapia, Myonia, Olpæ, Potidania, Teichium, and Tritæa.

LODÈVE, a town of S. France, capital of a cognominal arrondissement in the department of Hérault, on the Ergue, near its junction with the Saloudres, 110 miles W. by N. of Marseilles. It is encompassed by a wall, and its streets are narrow and irregular. The only building worthy of notice is the church of St Etienne, formerly a cathedral, which contains some interesting and beautiful monuments; one of these being a white marble mausoleum inclosing the remains of a Bishop of Lodève. The principal manufactures of the place comprise woollen cloths, soap, and leather: the first being used extensively for army clothing. Dyeing is also carried on here, and a brisk trade in wines, brandy, and fruit. Lodève is the seat of chambers of commerce and manufactures, and a council of *prud'hommes*. Pop. (1851) 10,793.

LODGE, THOMAS, a dramatist, was born about 1556 in Lincolnshire. In 1573 he entered Oxford as a servitor of Trinity College, but left it without taking a degree, and repaired to London. There he seems to have become an actor, and to have begun to write for the stage about 1580, when he produced his *Defence of Stage Plays*, in answer to Gosson's *School of Abuse*. In 1584 he was a student at Lincoln's Inn, and published, among other works, his *Alarum against Usurers*. Soon after this he accompanied Captain Clarke on his voyage to Terceira and the Canaries; and while sailing through the Straits of Magellan, in company with Cavendish, he wrote his *Margerite of America*, which was published in 1596. Some time after this period, according to Wood, he studied medicine, and took a degree at Avignon. On his return to London he is supposed to have practised with great success as a physician, and to have published in 1603 a *Treatise of the Plague*. Wood says he died of the plague in September 1625.

As a dramatist, he is placed by Collier "in a rank superior to Greene, but in some respects inferior to Kyd." His extant plays are two—*The Wounds of Civil War* lively set forth in the true Tragedies of Marius and Sylla, 4to, 1594, reprinted in the last edition of Dodsley's *Old Plays*; and *A Looking-Glass for London and England*, written in conjunction with Greene, published 1594, and after passing through several editions, reprinted in 1617. A collection of his pastoral and lyric poetry was published in 1819. His novel, entitled *Rosalynde: Euphues Golden Legacie*, 4to, 1590 (reprinted in Collier's *Shakspeare's Library*, 1840), furnished Shakspeare with the framework of the plot in "As You Like It."

LODI, an episcopal and walled city of N. Italy, capital of a cognominal province of Lombardy, on the right bank of the Adda, a tributary of the Po, 18 miles S.E. of Milan. It consists of well-built streets, and a great square, and

contains several interesting public buildings. The principal of these are,—the cathedral, in the Lombard style of architecture, with many fine pictures and carvings; the church of the *Incoronata*, founded in 1476, also containing some interesting paintings; the bishop's palace; and the town-house, a plain but handsome edifice. Besides these there are a royal college, a gymnasium, a theological school, three hospitals, a public library, and several churches and convents. The manufactures of the place consist of delft, pottery, linen, and silk. A large trade is carried on in Parmesan cheese, made in the neighbourhood. The ancient Laus Pompeia occupied a site 5 miles W. of the modern Lodi. It was, according to Pliny, settled by the Boii, a Gallic tribe, and afterwards became a Roman municipality. In the middle ages, under the name of Lodi, it became of such importance that it provoked the jealousy of the Milanese, who took and destroyed it in 1158. The inhabitants were then removed by the Emperor Frederick to the present city, which, however, never rose to the importance of its original. The site of Laus Pompeia is now occupied by a village called Lodi Vecchio. Pop. of Lodi, 18,986. In modern times Lodi is famous for the contest which took place on its bridge over the Adda, between the French under Bonaparte and the Austrians, on which occasion the latter were signally defeated.

LODI, a province of Lombardy, or Austrian Italy, in the government of Milan, bounded N. by Bergamo and Milan, E. by Cremona and Brescia, S. by the duchy of Parma, and W. by Pavia and Milan. It is about 28 miles in length from E. to W., by nearly the same in breadth, and contains an area of 290,359 acres. The surface is flat, or gently undulating. The soil is rich and well cultivated. The chief rivers are the Po, which separates the province from Parma, the Adda, the Lambro, and the Serio. Irrigation is also extensively carried on here, especially for the production of rich pasture. The chief products are rice, maize, flax, cheese, wine, and silk. The last has been much attended to of late, and the growing of mulberry trees is rapidly extending. The cheese of Lodi called Parmesan, is famous, and its manufacture gives employment to a large number of the inhabitants. The province is divided into 7 districts, 175 communes, and 160 parishes. In the eighteenth century it formed the two provinces of Lodi and Crema; the former belonging to Milan, and the latter to Venice. Pop. (1850) 222,166. See also **LOMBARDY**.

LOFODEN ISLANDS, a large group of islands off the N.W. coast of Norway, stretching N.E. to S.W. from N. Lat. 67. 30. to 69. 30., and E. Long. 12. to 16. 30. The group resembles the vertebrae of an animal in form; the islands fitting into each other so closely, that from a distance they seem to form one long continent. The islands, which are all of a granite or limestone formation, are precipitous and very lofty; the hills of Vaagoe rising almost perpendicularly to a height of 4000 feet above the sea. The channels which separate them are narrow, tortuous, and generally of great depth. The largest islands of the group are in the N., viz., Hindoe, Andoe, and Langoe; the first being separated from the mainland by a passage about a mile in width. The tail of the chain is formed of a number of smaller islands, the chief of which are the two Vaagoes, Moskenösoe, Væroe, and Rost, separated from the mainland by West Fiord. This gulf is much dreaded by mariners when the wind is S.W., on account of the great swell which rolls in from the North Sea, and which is especially dangerous at the Mälstroem channel between Væroe and Moskenösoe. The mean temperature of the group ranges from 23° in winter to 50° in summer, which, considering the high latitude, is comparatively mild. This is caused, however, by the exposure of the group to the gulf stream. Large shoals of herring and cod frequent the Lofodens annually, and attract to these islands a large

Lodi
||
Lofoden
Islands.

Logan. {concourse of fishing-boats from several hundreds of miles of sea-coast. In the inclement months of February and March, generally about 3000 boats (mostly open) assemble here for the cod-fishing, each having, on an average, five of a crew, while the aggregate number of fish taken amounts to more than three millions. These are chiefly dried in the sun and wind, without salt, and sent to Tromsøe, Trondhjem, Bergen, &c., along with large quantities of cod-liver oil and cod-roë, for exportation or home consumption. The cod-fishery ends in April, and is followed by the herring-fishing, which is carried on till the boisterous season at the end of autumn. The permanent population of the Lofodens is very small, considering the extent of territory, and is sustained principally by the fisheries. Some cattle, however, are kept in the most sheltered parts of the island, where good pasturage is obtained in the summer. Steilo, in the island of Ulvo, is the chief village of the group, and has communication with the ports of the mainland by means of a steamer, which visits the Lofodens in summer. Estimated pop. of group, 4000.

LOG, in nautical language, is a piece of wood usually in the form of a quadrant, with a radius of six inches. About a quarter of an inch in thickness, it is so loaded with a leaden plate, fastened to its circular side, that it swims in the water in a perpendicular position, with two-thirds under the surface.

LOG-LINE, *The*, used in navigation so early as 1570, and alluded to by Bourne in 1577, is a small cord with one end attached to the log, and the other to a revolving reel on board the ship. When the log is thrown overboard it keeps its place, as already described, while the log-line is unwound from the reel as the ship moves on, so that the length of line unwound in a given time indicates the rapidity of the ship's motion. The length of line given out is determined by pieces of coloured cloth called *knots* attached to it at distances of 50 feet, while the time is ascertained by a sand-glass of a given number of seconds, which bear nearly the same proportion to an hour that 50 feet bear to a mile. The number of knots, therefore, unwound from the reel in half a minute is the number of miles nearly which the ship runs in an hour. The log-line used by the royal navy is 48 feet in length.

LOGAN, JOHN, the author of the *Ode to the Cuckoo* and other poems, was the son of a small farmer, and was born at Fala, county of Edinburgh, in 1748. After receiving his elementary education at Musselburgh, he entered the University of Edinburgh in 1762, with the intention of becoming a dissenting minister. There he studied the learned languages with great success, cultivating at the same time, in the society of his class-fellow, Michael Bruce, his native taste for poetry. In 1766 he entered the class of rhetoric and belles-lettres; and having attracted the notice of the professor, Dr Blair, by a critical paper on the *Spectator*, he was recommended by him, in 1768, as tutor to Mr, afterwards Sir John, Sinclair, the eminent statist. This situation he soon relinquished, and returning to Edinburgh, he resumed his theological studies in connection with the Established Church. In 1770, editing the works of his deceased friend, Michael Bruce, he introduced indiscriminately among them several poems of his own, which were afterwards claimed for the former poet. Of these, the most disputed, because the best, is the well-known *Ode to the Cuckoo*. Its authorship is now generally ascribed to Logan, on the ground that, long before its publication, he showed it to many of his friends as his own, and that his claim was never questioned during his life—proofs which the weight of evidence in favour of Bruce fails to balance. Some of Logan's most popular hymns are also said (and perhaps justly) to have been perfected out of some unformed thoughts and images that Bruce left in MS. In 1773 he was licensed as a preacher, and was appointed minister of South Leith.

Not content with the high excellence which he soon attained as an eloquent preacher, he applied himself to historical studies; and at Edinburgh, in 1779, delivered a course of lectures on the philosophy of history, which were published in a condensed form in 1781. So marked did he become in this new capacity, that he would undoubtedly have been promoted, in 1780, to the chair of universal history at Edinburgh, had it not been an invariable custom for the patrons to elect a member of the Scottish bar. In 1781 were published his *Lecture on the Manners and Government of Asia* and the first edition of his *Poems*; and after a year the latter reached a second edition. In 1783 Logan produced his *Runnemedie*, a tragedy founded on the granting of the Magna Charta. On account of some political allusions, it was interdicted by the Lord Chamberlain during its rehearsal at Covent Garden Theatre; but it was acted the same year at Edinburgh, though with little success. His parishioners, offended at this unclerical use of his talents, now openly condemned him; and in 1786, being charged with drunkenness, he was forced to retire upon a part of his stipend. He had repaired to London in the preceding year, and devoted himself to literature. Besides several contributions to the *English Review*, he produced, in 1788, *A Review of the Principal Charges against Mr Hastings*, a pamphlet which advocated the defendant so ably, that the friends of the impeachment arraigned the publisher, Stockdale, for a breach of the privileges of the House of Commons. In the same year Logan published, under the name of Dr Rutherford, *A View of Ancient History*. After a lingering illness, he died on 28th December 1788.

His friend Dr Robertson published the first volume of his *Sermons* in 1790, and the second in 1791. Among his MSS. were also found, but never published, four tragedies (two of which were unfinished), six lyric poems, several parts of an intended periodical called the *Guardian*, and twenty-five *Lectures on Roman History*.

Logan's peculiar merit lay in the successful treatment of old and familiar themes,—a gift peculiar alike to a popular preacher and a lyric poet. Subjects that had become faded and worn through frequent handling, were rendered new and attractive to the eye by the fine polish of his diction, and the fresh hues of his fancy. The literary ability and the tender pathos of his sermons have saved them from that neglect to which kindred works are, with few exceptions, doomed. Of his poems, the best are the *Ode to the Cuckoo* and the *Hymns* forming part of the paraphrases used by the Church of Scotland. The latter are pervaded by a delicate and often plaintive strain of feeling. The simple diction and finely-woven fancies of the former entitle its author to a high rank as a lyricist. A third edition of Logan's *Poems*, accompanied by his *Life*, was published in 1805. A new edition of his *Sermons*, with a *Life* prefixed, appeared in London, 1810.

LOGGAN, DAVID, an engraver of considerable reputation, was born at Dantzic in 1635. He received the first lessons of his art from Simon Passe in Denmark, and subsequently, on paying a visit to Holland, he further perfected himself in the study under the guidance of Hondius. He came to England in the time of the Commonwealth, and engaged in engraving portraits and landscape pieces. The first work of Loggan, however, which attracted general notice, and gained for its author very considerable reputation, was his views of the Universities of Oxford and Cambridge. Having married into a good family near Oxford in 1672, he took up his residence there, and shortly afterwards published a large folio volume of plates: *Habitus Academicorum Oxoniæ, a Doctore ad Servientem*, by David Loggan, *Gedaniensis, Universitatis Oxoniæ Chalographus*. His engravings are remarkable for the neatness and accuracy of their execution, but this quality sometimes degenerates into stiffness and formality.

Loggan. {

LOGARITHMS.

I.—HISTORY OF LOGARITHMS.

History. THE labour and time required for performing the arithmetical operations of multiplication, division, and the extraction of roots, were at one time considerable obstacles to the improvement of various branches of knowledge, and in particular the science of astronomy. But about the end of the sixteenth century and the beginning of the seventeenth, several mathematicians began to consider by what means they might simplify these operations, or substitute for them others more easily performed. Their efforts produced some ingenious contrivances for abridging calculations; but of these the most complete by far was that of John Napier, baron of Merchiston, in Scotland, who invented a system of numbers called *logarithms*, so adapted to the numbers to be multiplied or divided, that these being arranged in the form of a table, each opposite the number called its logarithm, the product of any two numbers in the table was found opposite that formed by the addition of their logarithms; and, on the contrary, the quotient arising from the division of one number by another was found opposite that formed by the subtraction of the logarithm of the divisor from that of the dividend; and similar simplifications took place in the still more laborious operations of involution and evolution. But before we proceed to relate more particularly the circumstances of this invention, it will be proper to give a general view of the nature of logarithms, and of the circumstances which render them of use in calculation.

Let there be formed two series of numbers, the one constituting a geometrical progression, whose first term is unity or 1, and the common ratio any number whatever; and the other an arithmetical progression, whose first term is 0, and the common difference also any number whatever; for example, suppose the common ratio of the geometrical series to be 2, and the common difference of the arithmetical series 1, and let them be written thus:

Geom. Prog.	Arith. Prog.
1	0
2	1
4	2
8	3
16	4
32	5
64	6
128	7
256	8
512	9
1024	10
2048	11
4096	12
&c.	&c.

Here the terms in the arithmetical series are called the *logarithms* of the corresponding terms of the geometrical series; that is, 0 is the logarithm of 1, and 1 is the logarithm of 2, and 2 is the logarithm of 4, and 3 that of 8, and so on.

From the manner in which the two series are related to each other, it will readily appear by induction that the logarithms of the terms of the geometrical series have the two following properties:

1. The sum of the logarithms of any two numbers or terms in the geometrical series is the logarithm of that number, or term of the series, which is equal to their product.

For example, let the terms of the geometrical series be 4 and 32; the corresponding terms of the arithmetical series (that is, their logarithms) are 2 and 5: now the product of the numbers is 128, and the sum of their logarithms is 7; and it appears by inspection of the two series, that the latter number is the logarithm of the former, agreeing with the proposition we are illustrating. In like manner, if the numbers or terms of the geometrical series be 16 and 64, the logarithms of which are 4 and 6, we find from the table that $10 = 4 + 6$ is the logarithm of $1024 = 16 \times 64$; and so of any other numbers in the table.

2. The difference of the logarithms of any two numbers or terms of the geometrical series is the logarithm of that term which is the quotient arising from the division of the one number by the other.

Take, for example, the terms 128 and 32, the logarithms of which are 7 and 5; the greater of these numbers divided by the less is 4, and the difference of their logarithms is 2; and by inspecting the two series, this last number will be found to be the logarithm of the former. In like manner, if the terms of the geometrical series be 1024 and 16, the logarithms of which are 10 and 4, we find that $1024 \div 16 = 64$, and that $10 - 4 = 6$; now, in the table, the latter number, viz. 6, is the logarithm of the former, 64.

These two properties of logarithms, the second of which indeed is an immediate consequence of the first, enable us to find with great facility the product or the quotient of any two terms of a geometrical series to which there is adapted an arithmetical series, so that each number has its logarithm opposite to it, as in the preceding short table. For it is evident, that to multiply two numbers, we have only to add their logarithms, and opposite to that logarithm which is the sum we shall find the product required. Thus, to multiply 16 by 128; to 4 the logarithm of 16, add 7 the logarithm of 128, and opposite the sum 11, we find 2048, the product sought. On the other hand, to divide any number in the table by any other, we subtract the logarithm of the divisor from that of the dividend, and look for the remainder among the logarithms, and opposite to it we find the number sought. Thus, to divide 2048 by 128; from 11, the logarithm of 2048, we subtract 7, the logarithm of 128, and opposite the remainder 4, we find 16, the quotient sought.

Let us now suppose any number of geometrical means to be interposed between each two adjoining terms of the preceding geometrical series, and the same number of arithmetical means between every two adjoining terms of the arithmetical series; then, as the results will still be a geometrical and an arithmetical series, the interpolated terms of the latter will be the logarithms of the corresponding terms of the former, and the two new series will have the very same properties as the original series.

If we suppose the number of interpolated means to be very great, it will follow that among the terms of the resulting geometrical series, some one or other will be found nearly equal to any proposed number whatever. Therefore, although the preceding table exhibits the logarithms of 1, 2, 4, 8, 16, &c. but does not contain those of the intermediate numbers, 3, 5, 6, 7, 9, 10, &c. yet it is easy to conceive that a table might be formed by interpolation which should contain, amongst the terms of the geometrical series, all numbers whatever to a certain extent (or at least others very nearly equal to them), together with their logarithms. If such a table were constructed, or at least if such terms

History. of the geometrical progression were found, together with their logarithms, as were either accurately equal to, or coincided nearly with, all numbers within certain limits (for example, between 1 and 100,000), then, as often as we had occasion to multiply or divide any numbers contained in that table, we might evidently obtain the products or quotients by the simple operations of addition and subtraction.

The first invention of logarithms has been attributed by some to Longomontanus, and by others to Juste Byrge, two mathematicians contemporary with Napier; but there is no reason to suppose that either of these anticipated him, for Longomontanus never published any thing on the subject, although he lived thirty-three years after Napier had made known his discovery; and as to Byrge, he is indeed known to have printed a table containing an arithmetical and a geometrical progression written opposite to each other, so as to form in effect a system of logarithms of the same kind as those invented by Napier, without however explaining their nature and use, although it appears from the title he intended to do so, but was probably prevented by some cause unknown to us. But this work was not printed till 1620, six years after Napier had published his discovery, namely, in 1614, in a book entitled *Mirifici Logarithmorum Canonis Descriptio*; but he reserved the construction of the numbers till the opinion of the learned concerning his invention should be known. It is therefore with good reason that Napier is now universally considered as the first, and most probably the only inventor. His work contains a table of the natural sines and cosines, and their logarithms, for every minute of the quadrant, as also the differences between the logarithmic sines and cosines, which are in effect the logarithmic tangents. There is no table of the logarithms of numbers; but precepts are given, by which they, as well as the logarithmic tangents, may be found from the table of natural and logarithmic sines.

In explaining the nature of logarithms, Napier supposes some determinate line which represents the radius of a circle to be continually diminished, so as to have successively all possible values, and thus to be equal to every sine, one after another, throughout the quadrant. And he supposes this diminution to be effected by a point moving from one extremity towards the other extremity (or rather some point very near it), with a motion that is not uniform, but decreases gradually in such a manner, that if the whole time between the beginning and the end of the motion be conceived to be divided into a very great number of equal portions, the decrements taken away in each of these shall be to one another as the respective remainders of the line. According to this mode of conceiving the line to decrease, it is easy to show that at the end of any successive equal intervals of time from the beginning of the motion, the portions of the line which remain will constitute a decreasing geometrical progression.

Again, he supposes another line to be generated by a point which moves along it equably, or which passes over equal intervals of it in equal times. Thus the portions of the line generated at the end of any equal successive intervals of time from the beginning of the motion will form a series of quantities in arithmetical progression. Now if the two motions be supposed to begin together, the remainders of the one line at the end of any equal intervals of time will form a series of quantities in geometrical progression, while the corresponding portions generated of the other line will constitute a series in arithmetical progression, so that the latter will be the logarithms of the former. And as the terms of the geometrical progression decrease continually from radius, which is the greatest term, to 0, while the terms of the corresponding arithmetical progression increase from 0 upwards, according to Napier's system the logarithm of radius is 0, and the logarithms of the sines

from radius down to 0 are a series of numbers increasing from 0 to infinity.

The velocities or degrees of quickness with which the motions commence may have to each other any ratio whatever, and by assuming different ratios we obtain different systems of logarithms. Napier supposed the initial velocities to be equal; but the system of logarithms produced in consequence of this assumption having been found to have some disadvantages, it has been long superseded by a more convenient one, as we shall presently have occasion to explain.

Napier's work having been written in Latin, was translated into English by Mr Edward Wright, an ingenious mathematician of that period, and inventor of the principles of what is commonly though erroneously called *Mercator's sailing*. The translation being sent to Napier for his perusal, was returned with his approbation, and with the addition of a few lines, intimating that he intended to make some alterations in the system of logarithms in a second edition. Mr Wright died soon after he received back his translation; but it was published after his death in 1616, accompanied with a dedication by his son to the East India Company, and a preface by Henry Briggs, who afterwards distinguished himself by improving the form or system of logarithms. Mr Briggs likewise gave in this work the description and draught of a scale which had been invented by Wright, as also various methods of his own for finding a logarithm to a given number, and a number to a given logarithm, by means of Napier's table, the use of which had been attended with some inconvenience, on account of its containing only such numbers as were the natural sines to every minute of the quadrant and their logarithms. There was an additional inconvenience in using the table, arising from the logarithms being partly positive and partly negative. The latter of these was, however, well remedied by John Speidell in his *New Logarithms*, first published in 1619, which contained the sines, cosines, tangents, cotangents, secants, and cosecants, and given in such a form as to be all positive; and the former was still more completely removed by an additional table, which he gave in the sixth impression of his work in 1624, and which contained the logarithms of the integers 1, 2, 3, 4, &c. to 1000, together with their differences and arithmetical complements, &c. This table, which is of great use in finding fluents, is commonly called *hyperbolic logarithms*, because the numbers serve to express the areas contained between a hyperbola and its asymptote, and limited by ordinates drawn parallel to the other asymptote. This name, however, is certainly improper, as the same spaces may represent the logarithms of any system whatever.

In 1619, Robert Napier, son of the inventor of logarithms, published a second edition of his father's *Logarithmorum Canonis Descriptio*; and, along with this, the promised *Logarithmorum Canonis Constructio*, and other pieces written by his father and Mr Briggs. An exact copy of the same two works in one volume was also printed in 1620 at Lyons in France. In 1618 or 1619, Benjamin Ursinus, mathematician to the elector of Brandenburg, published Napier's tables of logarithms in his *Cursus Mathematicus*, to which he added some tables of proportional parts; and in 1624 he printed his *Trigonometria*, with a table of natural sines, and their logarithms of the Napierian kind and form, to every ten seconds of the quadrant.

In the same year, 1624, the celebrated John Kepler published, at Marburg, logarithms of nearly the same kind, under the title of *Chilias Logarithmorum ad totidem Numeros Rotundos, præmissa Demonstratione legitima Ortus Logarithmorum eorumque Usus*, &c.; and in the following year he published a supplement to this work. In the

History. preface to this last he says, that several of the professors of mathematics in Upper Germany, and more especially those who were advanced in years, and grown averse to new methods of reasoning which carried them out of their old principles and habits, doubted whether Napier's demonstration of the property of logarithms was perfectly true, and whether the application of them to trigonometrical calculations might not be unsafe, and lead the calculator who should trust in them to erroneous results; and in either case, whether the doctrine were true or not, they scarcely considered Napier's demonstration of it as legitimate and satisfactory. This opinion induced Kepler to compose the above-mentioned work, in which the whole doctrine is treated in a manner strictly geometrical, and free from the considerations of motion to which those elderly Germans had objected.

On the publication of Napier's Logarithms, Mr Henry Briggs, some time professor of geometry in Gresham College, London, and afterwards Savilian professor of geometry at Oxford, applied himself with great earnestness to the study and improvement of them. From the particular view which Napier took of the subject, and the manner in which he conceived logarithms to be generated, it happened that in his system the logarithms of a series of numbers which increased in a decuple ratio (as 1, 10, 100, 1000, &c.) formed a decreasing arithmetical series, whose common difference was 2.3205851. But it occurred to Briggs that it would be better and more conformable to the received decimal notation, to adopt a system in which the logarithms of the terms of such a geometrical series should differ from each other by unity or 1. This idea Briggs communicated to the public in his lectures, and also to Napier himself. He even went twice to Edinburgh to converse with him on the subject; and, on his first visit, Napier said that he had also formerly thought of the same improvement, but that he chose to publish the logarithms he had previously calculated, till such time as his health and convenience would allow him to make others more commodious. And whereas, in the change which Briggs proposed, it was intended to make the logarithms of the sines to increase from 0 (the logarithm of radius) to infinity, whilst the sines themselves should decrease, it was suggested to him by Napier that it would be better to make them increase, so that 0, instead of being the logarithm of radius, should be the logarithm of 1, and that 100,000, &c. should be the logarithm of radius. This Briggs admitted would be an improvement; and having changed the numbers he had already calculated so as to make them suit Napier's modification of his plan, he returned with them next year to Edinburgh, and submitted them to his perusal.

It appears, therefore, that whether Napier or Briggs was the inventor of this improved system of logarithms which has since been universally adopted, Napier had suggested to begin with the low number 1, and to make the logarithms, or the artificial numbers, as he had always called them, to increase with the natural numbers, instead of decreasing; which, however, made no alteration in the figures, but only in their affections or signs, changing them from negative to positive.

On Briggs's return from Edinburgh, in 1617, he printed the first thousand logarithms to eight places of figures, besides the index, with the title of *Logarithmorum Chilias prima*; but these seem not to have been published till after the death of Napier, for in his preface he expresses a hope that the circumstances which led to a change in the system would be explained in Napier's posthumous work, about to appear. But although Napier had intimated in a note he had given in Wright's translation of the *Canon Mirificus*, as well as in his *Rabdologia*, printed in 1617, that he intended to alter the scale, yet he does not state

History. that Briggs was the first to think of this improvement, or to publish it. And as nothing was said on this point in Napier's posthumous work published in 1619 by his son, Briggs took occasion, in his *Arithmetica Logarithmica*, to assert his claims to the improvement which he had carried into execution. But he has by no means proved that he himself, and not Napier, was the first who had thought of such improvements.

In 1620, Mr Edmund Gunter published his *Canon of Triangles*, which contains the artificial or logarithmic sines and tangents to every minute to seven places of figures besides the index, the logarithm of radius being 10. These logarithms are of the kind which had been agreed upon between Napier and Briggs, and they were the first tables of logarithmic sines and tangents that were published of this sort. Gunter also, in 1623, reprinted the same in his book *De Sectoris et Radio*, together with the *Chilias prima* of Briggs; and in the same year he applied the logarithms of numbers, sines, and tangents, to straight lines drawn upon a ruler. This instrument is now in common use for navigation and other purposes, and is commonly called *Gunter's Scale*.

The discoveries in logarithms were carried to France by Mr Edmund Wingate, but not first of all, as he says in the preface to his book. He published at Paris in 1624 two small tracts in French upon logarithms, which were reprinted with improvements at London in 1626.

In the year 1624, Briggs published his *Arithmetica Logarithmica*, a stupendous work, considering the short time he had been in preparing it. He there gives the logarithms of 30,000 natural numbers to fourteen places of figures, besides the index; namely, from 1 to 20,000, and from 90,000 to 100,000, together with the differences of the logarithms. He also gives an ample treatise on their construction and use, and he earnestly solicits others to undertake the computation of the intermediate numbers, offering to give instructions, and paper ready ruled for that purpose, to any person inclined to contribute to the completion of so valuable a work. By this invitation, he had hopes of collecting materials for the logarithms of the intermediate 70,000 numbers, whilst he should employ his time upon the Canon of Logarithmic Sines and Tangents, and so carry on both works at once.

Soon after this, Adrian Vlacq or Flack of Gouda, in Holland, completed the intermediate 70 chiliads, and republished the *Arithmetica Logarithmica* in 1627 and 1628, with these intermediate numbers, making in all the logarithms of all numbers to 100,000, but only to 10 places of figures. To these was added a table of artificial sines, tangents, and secants, to every minute of the quadrant.

Briggs himself lived also to complete a table of logarithmic sines and tangents, to the 100th part of every degree to fourteen places of figures, besides the index, together with a table of natural sines to the same parts to fifteen places, and the tangents and secants of the same to ten places, with the construction of the whole. But death prevented him from completing the application and uses of them. However, when dying, he committed this to his friend Henry Gellibrand, who accordingly added a preface, and the application of the logarithms to plane and spherical trigonometry. The work was called *Trigonometria Britannica*, and was printed at Gouda in 1633, under the care of Adrian Vlacq, who in the same year printed his own *Trigonometria Artificialis, sive Magnus Canon Triangulorum Logarithmicus ad Decadas Secundorum Scrupulorum Constructus*. This contains the logarithmic sines and tangents to 10 places of figures, with their differences for every ten seconds in the quadrant. It also contains Briggs's table of the first 20,000 logarithms to ten places, besides the index, with their differences; and to the whole is prefixed a description of the tables and their applications,

History. chiefly extracted from Briggs's *Trigonometria Britannica* just mentioned.

Gellibrand also published, in 1635, *An Institution Trigonometrical*, containing the logarithms of the first 10,000 numbers, with the natural sines, tangents, and secants, and the logarithmic sines and tangents, for degrees and minutes; all to seven decimal places.

The writers whose works we have hitherto noticed were for the most part computors of logarithms. But the system best adapted to practice being now well ascertained, and the labour of constructing the table accomplished, succeeding writers on the subject have had little more to do than to give the tables in the most convenient form. It is true, that in consequence of the numerous discoveries which were afterwards made in mathematics, particularly in the doctrine of series, great improvements were made in the method of computing logarithms; but these, for the most part, came too late to be of use in the actual construction of the tables, although they might be applied with advantage to verify calculations previously performed by methods much more laborious, and to detect various errors which had crept into the numbers.

As it is of importance that such as have occasion to employ logarithms should know what works are esteemed for their extent and accuracy, we shall mention the following:

Sherwin's *Mathematical Tables*, in 8vo. These contain the logarithms of all numbers to 101,000; and the sines, tangents, secants, and versed sines, both natural and logarithmic, to every minute of the quadrant. The third edition, printed in 1742, which was revised by Gardiner, is esteemed the most correct; but, in the fifth edition, the errors are so numerous, that no dependence can be placed on it.

Gardiner's *Tables of Logarithms* for all numbers to 101,000, and for the sines and tangents to every ten seconds of the quadrant; also for the sines of the first 72 minutes to every single second, &c. This work, which is in quarto, was printed in 1742, and is held in high estimation for its accuracy. An edition of the same work, with some additions, was printed in 1770, at Avignon, in France; and another by Callet at Paris in 1783, with farther improvements. The tables in both are to seven places of figures.

Hutton's *Mathematical Tables*, containing common, hyperbolic, and logistic logarithms, &c. and much valuable information respecting the history of logarithms, and other branches of mathematics connected with them.

Taylor's *Table of Logarithmic Sines and Tangents to every second of the quadrant*; to which is prefixed an able introduction by Dr Maskelyne, and a table of logarithms from 1 to 100,000, &c. This is a most valuable work; but being a large quarto volume, and rather expensive, it is less accessible than the preceding, which is an octavo, at a moderate price.

Tables portatives des Logarithmes, contenant les Logarithmes des nombres depuis 1 jusqu'à 108,000; les logarithmes des sinus et tangentes, de seconde en seconde pour les cinq premiers degrés, de dix en dix secondes pour tous les degrés du quart de cercle, et suivant la nouvelle division centésimale de dix-millième en dix millième, &c. par Callet. This work is in octavo, and printed in stereotype by Didot.

There are various smaller sets of tables; but probably the most accurate of all are those which Professor Babbage has produced with his very ingenious calculating machine, which has enabled him to detect a variety of errors in former tables. But, what is rather amusing, on examining a set of tables printed in the Chinese character, and which, like every Chinese invention, were older than the deluge, Mr Babbage found they contained

precisely the same errors as those of Vlacq did; thus proving, as had long been suspected, from what source those original inventors had derived their logarithms.

In addition to these, it is proper that we should notice a stupendous work relating to logarithms, originally suggested by the celebrated Carnot, in conjunction with Prieur de la Côte d'Or, and Brunet de Montpellier, about the beginning of the French revolution. This enterprise was committed in 1794 to the care of Baron de Prony, a mathematician of great eminence, who was *not only to compose tables which should leave nothing to be desired with respect to accuracy, but to make them the most extended and most striking monument of calculation ever executed or imagined*. Two manuscript copies of the work, composed of seventeen volumes large folio, contained, besides an introduction,

1. The natural sines for each 10,000th part of the quadrant, calculated to twenty-five places of decimals, to be published with twenty-two decimals and five columns of differences.

2. The logarithms of these sines, calculated to fourteen decimals, with five columns of differences.

3. The logarithms of the ratios of the sines to the arcs for the first five thousand 100,000th parts of the quadrant, calculated to fourteen decimal places, with three columns of differences.

4. The logarithms of the tangents corresponding with the logarithms of the sines.

5. The logarithms of the ratios of the tangents to the arcs, calculated like those of the third article.

6. Logarithms of numbers from 1 to 100,000, calculated to nineteen places of decimals.

7. The logarithms of numbers from 100,000 to 200,000, calculated to twenty-four decimals, in order to be published to twelve decimals and three columns of differences.

The printing of this work, though begun by the French government, was afterwards suspended.

Shortrede's Tables.—These tables contain the logarithms to numbers from 1 to 120,000, and numbers to logarithms from 0 to 1.00000; tables with centesimal and decimal arguments for finding logarithms and antilogarithms, as far as sixteen and twenty-five places; tables to five places for finding the logarithms of the sums and differences of antilogarithms, &c.; tables of natural sines, cosines, &c., to every second of arc in the quadrant; tables containing angles which every point and quarter-point of the compass makes with the meridian in points and degrees; tables of logarithmic sines, cosines, tangents, &c., to every second of the circle, with arguments in space and time.

II.—NATURE OF LOGARITHMS AND THEIR CONSTRUCTION.

The first step to be taken in constructing a system of logarithms is to assume the logarithm of some determinate number, besides that of unity or 1, which must necessarily be 0. From the particular view which Napier first took of the subject, he was led to assume unity for the logarithm of the number 2.718282, by which it happened that the logarithm of 10 was 2.302585; and this assumption being made, the form of the system became determinate, and the logarithm of every number fixed to one particular value.

It was, however, soon observed, that it would be better to assume unity for the logarithm of 10, instead of making it the logarithm of 2.718282, as in Napier's first system; and hence the logarithms of the terms of the geometrical progression

1, 10, 100, 1000, 10,000, &c.

were necessarily fixed to the corresponding terms of this arithmetical progression,

0, 1, 2, 3, 4, &c.

Nature
of Loga-
rithms.

Nature
of Loga-
rithms.

That is, the logarithm of 1 being 0, and that of 10 being 1, the logarithm of 100 is 2, that of 1000 is 3, and so on.

The logarithms of the terms of the progression 1, 10, 100, 1000, &c. being thus determined; in order to form the logarithms of the numbers between 1 and 10, and between 10 and 100, and so on, we must conceive a very great number of geometrical means to be interposed between each two adjoining terms of the preceding geometrical series, and as many arithmetical means between the corresponding terms of the arithmetical series; then, like as the terms of the arithmetical series 0, 1, 2, 3, &c. are the logarithms of the corresponding terms of the geometrical series 1, 10, 100, 1000, &c. the interpolated terms of the former will also be the logarithms of the corresponding interpolated terms of the latter. Now, by supposing the number of means interposed between each two terms of the geometrical series to be sufficiently great, some one or other of them may be found which will be very nearly equal to any proposed number. Hence, to find the logarithm of such a number, we have only to seek for one of the interpolated means which is very nearly equal to it, and to take the logarithm of that mean as a near value of the logarithm required.

As a particular example, let it be required to find the logarithm of 5, according to Briggs's system.

First step of the process.—The number 5 is between 1 and 10, the logarithms of which we already know to be 0 and 1: Let a geometrical mean be found between the two former, and an arithmetical mean between the two latter. The geometrical mean will be the square root of the product of the numbers 1 and 10, which is 3.162277; and the arithmetical mean will be half the sum of the logarithms 0 and 1, which is 0.5; therefore the logarithm of 3.162277 is 0.5. But as the mean thus found is not sufficiently near the proposed number, we must proceed with the operation as follows:

Second step.—The number 5, whose logarithm is sought, is between 3.162277, the mean last found, and 10, the logarithms of which we know to be 0.5 and 1; we must now find a geometrical mean between the two former, and an arithmetical mean between the two latter. The one of these is $\sqrt{(3.162277 \times 10)} = 5.623413$, and the other is $\frac{1 + 0.5}{2} = 0.75$, the logarithm of 5.623413.

Third step.—We have now obtained two numbers, namely, 3.162277 and 5.623413, one on each side of 5, together with their logarithms 0.5 and 0.75; we therefore, proceeding as before, find the geometrical mean, or $\sqrt{(3.162277 \times 5.623413)}$, to be 4.216964, and the arithmetical mean $\frac{0.5 + 0.75}{2} = 0.625$, the logarithm of 4.216964.

Fourth step.—We proceed in the same manner with the numbers 4.216964, and 5.623413 (one of which is less and the other greater than 5), and their logarithms 0.625 and 0.75, and find a new geometrical mean, viz. 4.869674, and the corresponding arithmetical mean or logarithm 0.6875.

We must go on in this way till we have found twenty-two geometrical means, and as many corresponding arithmetical means or logarithms. And that we may indicate how these are found from each other, let the numbers 1 and 10 be denoted by A and B, and their geometrical means taken in their order by C, D, E, &c. then the results of the successive operations will be as in the following table:

	Numbers.	Logarithms.
A =	1.000000	0.000000
B =	10.000000	1.000000
C = \sqrt{AB}	3.162277	0.500000
D = \sqrt{BC}	5.623413	0.750000
E = \sqrt{CD}	4.216964	0.625000

Numbers. Logarithms.

F = \sqrt{DE}	4.869674	0.6875000
G = \sqrt{DF}	5.232991	0.7187500

Nature
of Loga-
rithms.

As the last of these means, viz. Z, agrees with 5, the proposed number, as far at least as the sixth place of decimals, we may safely consider them as very nearly equal, and therefore their logarithms very nearly equal; that is, the logarithm of 5 will be 0.6989700 nearly.

In performing the operations indicated in the preceding table, it is necessary to find the geometrical means at the beginning to many more figures than are here put down, in order to insure at last a result true to 7 decimal places. Thus it appears that the labour of computing logarithms by this method is indeed very great. It is, however, that which was employed by Briggs and Vlacq in the original construction of logarithms; but since their time more easy methods have been found, some of which we shall presently have occasion to explain, and to illustrate by actual computation.

The logarithm of any number whatever may be found by a series of calculations similar to that just explained. But in constructing the table it would only be necessary to have recourse to this method in calculating the logarithms of prime numbers; for as often as the logarithm of a number which was the product of other numbers, whose logarithms were known, was required, it would be immediately obtained by adding together the logarithms of its factors. On the contrary, if the logarithm of the product of two numbers were known, and also that of one of its factors, the logarithm of the other factor would be obtained from these, by simply taking their difference.

From this last remark it is obvious, that having now found the logarithm of 5, we can immediately find that of 2; for since 2 is the quotient of 10 divided by 5, its logarithm will be the difference of the logarithms of 10 and 5; now the logarithm of 10 is 1, and that of 5 is 0.6989700, therefore the logarithm of 2 is 0.3010300.

Having thus obtained the logarithms of 2 and 5, in addition to those of 10, 100, 1000, &c. we may thence find the logarithms of innumerable other numbers. Thus, because $4 = 2 \times 2$, the logarithm of 4 will be the logarithm of 2 added to itself, or will be twice the logarithm of 2. Again, because $5 \times 10 = 50$, the logarithm of 50 will be the sum of the logarithms of 5 and 10. In this manner it is evident we may find the logarithms of $8 = 2 \times 4$, of $16 = 2 \times 8$, of $25 = 5 \times 5$, and of as many more such numbers as we please.

Besides the view we have hitherto taken of the theory of logarithms, there are others under which it has been presented by different authors. Some of these we proceed to explain, beginning with that in which they are defined to be the *measures of ratios*; but to see the propriety of this definition, it must be understood what is meant by the measure of a ratio.

Nature
of Loga-
rithms.

According to the usual definition of a compound ratio, if there be any number of magnitudes A, B, C, D, in continued proportion, the ratio of the first, A, to the third, C, is considered as made up of two ratios, each equal the ratio of the first, A, to the second, B. And in like manner the ratio of the first, A, to the fourth, D, is considered as made of three ratios, each equal the same ratio of the first to the second, and so on. Thus, to take a particular example in numbers, because the ratio of 81 to 3 may be considered as made up of the ratio of 81 to 27, and of 27 to 9, and of 9 to 3, which three ratios are equal among themselves, the ratio of 81 to 3 will be triple that of 9 to 3; and in like manner the ratio of 27 to 3 will be double that of 9 to 3. Also, because the ratios of 1000 to 100, 100 to 10, 10 to 1, are all equal, the ratio of 1000 to 1 will be three times as great as that of 10 to 1; and the ratio of 100 to 1 will be twice as great; and so on.

Taking this view of ratios, and considering them as a particular species of quantities, made up of others of the same kind, they may evidently be compared with each other in the same manner as we compare lines or quantities of any kind whatever. And as, when estimating the relative magnitude of two quantities, two lines, for example, if the one contains five such equal parts as the other contains seven, we say the one line has to the other the proportion of 5 to 7; so, in like manner, if two ratios be such, that the one can be resolved into five equal ratios, and the other into seven of the same ratios, we may conclude that the magnitude of the one ratio is to that of the other as the number 5 to the number 7; and a similar conclusion may be drawn, when the ratios to be compared are any multiples whatever of some other ratio.

Since lines and other quantities, which admit of no common measure, are said to be incommensurable to each other, the same will obviously happen to ratios; that is, there may be two ratios such, that into whatever number of equal ratios the one is divided, the other cannot possibly be exactly equal to a ratio composed of any integral number of these. We may, however, conceive the number of equal ratios into which the one is divided to be so great, that a certain number of them shall compose a ratio more nearly equal to the other ratio than by any assignable difference. Therefore, like as we can always find numbers which shall have among themselves, either accurately, or as nearly as we please, the same ratios as lines or other magnitudes have to each other, and which therefore may be taken as the measures or representatives of the lines; so also, corresponding to any system of ratios, there may be always found a series of numbers which will have the same proportions among themselves as the ratios have to each other, and which may in like manner be called the *measures of the ratios*.

Let us now suppose that unity, or 1, is assumed as the common consequent or second term of all ratios whatever; and that the ratio of 10 (or some particular number) to 1 is compounded of a very great number of equal ratios, as, for example, 1,000,000: then, as each of these will be very near the ratio of equality (for it will be the ratio of the first term to the second of a series consisting of one million and one continued proportionals, the first of which is 10 and last 1), it will follow, and is easy to conceive, that the ratios of all other numbers to unity will each be very nearly equal to some multiple of that small ratio. And by supposing the number of small equal ratios of which the ratio of 10 to 1 is composed, to be sufficiently great, the ratios of all other numbers to unity may be as nearly equal to ratios which are multiples of that small ratio, as we please. Let us still suppose, however, for the sake of illustration, that the number of small ratios contained in that of 10 to 1 is 1,000,000; then, as it may be proved that the ratio of 2 to 1 will be very nearly the same as a ratio

composed of 301,030 of these, and that the ratio of 3 to 1 will be nearly equal to a ratio composed of 477,121 of them, and that the ratio of 4 to 1 will be nearly equal to a ratio composed of 602,060 of them, and so on; these numbers, viz. 1,000,000, 301,030, 477,121, and 602,060, or any other numbers proportional to them, will be the *measures* of the ratios of 10 to 1, 2 to 1, 3 to 1, and 4 to 1, respectively; and the same quantities will also be what have been called the *logarithms* of the ratios; for the word *logarithm*, if regard be had to its etymology, is *λογῶν ἀριθμοί*, or the numbers of small and equal ratios (or *ratiunculae*, as they have been called) contained in the several ratios of quantities one to another.

We have, for the sake of illustration, assumed 1,000,000 as the measure of the ratio of 10 to 1, by which it happens, as already observed, that the measures of the ratios of 2 to 1, 3 to 1, &c. are 301,030 and 477,121 respectively; as, however, these measures are not absolute, but relative quantities, we may assume any other numbers whatever instead of these, provided they are proportional to them. Accordingly, we may assume 1 as the measure or logarithm of the ratio of 10 to 1; and then the logarithms of the ratios of 2 to 1, 3 to 1, &c. instead of being 301,030, 477,121, &c. will be .301030 and .477121, &c. respectively, that is, each will be one millionth of what it was before.

In Briggs's system, the logarithm of the ratio of 10 to 1, or, to speak briefly, the logarithm of 10, is unity; but we are at liberty to assume any number whatever, as that whose logarithm shall be unity. Napier, in consequence of his particular views, chose 2,718,282; and hence it happens that the logarithms of the ratios are expressed by different numbers in the two systems.

But, to show the identity of the properties of logarithms, as explained in the two different views now given of the subject, let A and B denote any two numbers. The ratio of their product to unity, that is, the ratio of $A \times B$ to 1, is compounded of the ratio of A to 1 and of B to 1; and consequently the logarithm of the ratio of $A \times B$ to 1 will equal the sum of the logarithms of the ratios of A to 1, and of B to 1; or, in other words, the logarithm of $A \times B$ will be the sum of the logarithms of A and B. Now, $\log. (A \times B) = \log. A + \log. B$, therefore, $\log. B = \log. (A \times B)$

— $\log. A$. Let $\frac{C}{D}$ be substituted for B, and D for A, then (because $A \times B = D \times \frac{C}{D} = C$) we have $\log. \frac{C}{D} = \log. C - \log. D$.

Such is a short sketch of the theory of logarithms as deducible from the doctrine of ratios. It was in this way that the celebrated Kepler treated the subject; and he has been followed by Mercator, Halley, and Cotes, as well as by mathematicians of later times, as by Baron Masenius in his Trigonometry. The same mode was likewise adopted in the posthumous works of Dr Robert Simson. As, however, the doctrine of ratios is very abstract, and the mode of reasoning upon which it has been established is of a peculiar and subtle kind, we presume that the greater number of readers will think this view of the subject less simple and natural than the following, in which we mean to deduce the theory of logarithms, as well as the manner of computing them, from the properties of the exponents of powers.

The common scale of notation in arithmetic is so contrived as to express all numbers whatever by the powers of 10, which is the root of the scale, and the nine digits serving as co-efficients to these powers. Thus, if R denote 10, the root of the scale, so that R^2 will denote 100, and R^3 1000, and so on, the number 471,509 is otherwise expressed by $4R^5 + 7R^4 + 1R^3 + 5R^2 + 0R^1 + 9R^0$, which is

Nature
of Loga-
rithms.

Nature of Logarithms. equivalent to $4R^5 + 7R^4 + R^3 + 5R^2 + 9$. Again, the mixed number 371.243 is expressed by $3R^2 + 7R^1 + R^0$

+ $\frac{2}{R} + \frac{4}{R^2} + \frac{3}{R^3}$, or by $3R^2 + 7R^1 + R^0 + 2R^{-1} + 4R^{-2} + 3R^{-3}$. As to vulgar fractions, by transforming them to decimals, they may be expressed in the same manner. Thus $\frac{2}{3} = .375 = 3R^{-1} + 7R^{-2} + 5R^{-3}$. Also $\frac{2}{3} = .666$, &c. $= 6R^{-1} + 6R^{-2} + 6R^{-3} + \&c.$

But instead of expressing all numbers by the sums of certain multiples of the successive powers of some particular number, we may also express them, if not accurately, at least as near as we please, by a single power, whole or fractional, of any positive number whatever, which may be either whole or fractional, but must not be unity.

Let us take, for example, 2 as the number, by the powers of which all others are to be expressed. Then it may be shown that the numbers 1, 2, 3, &c. are all expressible by the powers of 2, as follows.

$$\begin{array}{ll} 1 = 2^0 & 6 = 2^{2.58496} \text{ nearly} \\ 2 = 2^1 & 7 = 2^{2.8073} \text{ nearly} \\ 3 = 2^{1.58496} \text{ nearly} & 8 = 2^3 \\ 4 = 2^2 & 9 = 2^{3.1699} \text{ nearly} \\ 5 = 2^{2.3219} \text{ nearly} & 10 = 2^{3.3219} \text{ nearly} \end{array}$$

and so on. And if instead of 2 we take the number 10, then we have

$$\begin{array}{ll} 1 = 10^0 & 6 = 10^{.77815} \\ 2 = 10^{.30103} & 7 = 10^{.84510} \\ 3 = 10^{.47712} & 8 = 10^{.90309} \\ 4 = 10^{.60206} & 9 = 10^{.95424} \\ 5 = 10^{.69897} & 10 = 10^1. \end{array}$$

Hence we may conclude, that if r be put for some determinate number, and n for any indefinite positive number, whole or fractional, it is always possible to find another number N , such that r being raised to the power N , shall either be exactly equal to n , or as near it as we please; that is, we shall have $r^N = n$.

When numbers are expressed in this way by the powers of some given number r , the exponent of that power of r which is equal to any assigned number is called the logarithm of that number. Thus, if $r^N = n$ (n being put for any number), N is the logarithm of n .

The logarithms which are produced by giving to r some determinate value, constitute a system of logarithms; and the constant number r , from which the system is formed, is called the base, radix, or radical number of the system.

The properties of logarithms may readily be deduced from the above definition as follows: Let a and b be any two numbers, and A and B their logarithms; then r being supposed to denote the base or radical number of the system, we have $a = r^A$ and $b = r^B$: now if we take the product of a and b , we have $a b = r^A \times r^B = r^{A+B}$; but, according to the definition, $A+B$ is the logarithm of $a b$ (for it is the index of that power of r which is equal to $a b$), therefore the sum of the logarithms of any two numbers a and b is the logarithm of their product $a b$. Again, we

have $\frac{a}{b} = \frac{r^A}{r^B} = r^{A-B}$, but here $A-B$, being the index

of that power of r which is equal to $\frac{a}{b}$, is the logarithm of $\frac{a}{b}$;

hence, if one number a be divided by another b , the difference between their logarithms is the logarithm of the quotient $\frac{a}{b}$.

Let n express any number whatever, then raising both sides of the equation $a = r^A$ to the n th power, we have $a^n = (r^A)^n = r^{nA}$; but here nA is manifestly the logarithm of a^n ; therefore, the logarithm of a^n , any power of a number, is the product of the logarithm of the number by n , the index of the power. This must evidently be true, whether n be a whole number or a fraction, positive or negative.

From these properties, it is easy to see in what manner a table exhibiting the logarithms of all numbers within certain limits may be applied to simplify calculations; for since the sum of the logarithms of any two numbers is the logarithm of their product, it follows, that as often as we have occasion to find the product of two or more numbers, we have only to add their logarithms taken from the table into one sum, and to look for the number whose logarithm is equal to that sum, and this number will be the product required. Also, because the difference between the logarithm of the dividend and that of the divisor is the logarithm of the quotient, whenever we have occasion to divide one number by another, we have only to subtract the logarithm of the divisor from that of the dividend, and opposite to that logarithm in the table, which is the remainder, we find the quotient.

As the logarithm of any power of a number is the product of the logarithm of the number by the index of the power; and, on the contrary, the logarithm of any root of a number is the quotient found by dividing the logarithm of the number by the index of the root; it follows that we may find any power or root of a number by multiplying the logarithm of the number by the index of the power, or dividing it by the index of the root, and taking that number in the table whose logarithm is the product or quotient for the power or root required.

If in the equation $a = r^A$ (where a is any number, A its logarithm, and r the base of the system) we suppose $a = 1$, then $r^A = 1$; but this equation can only be satisfied by $A = 0$. Hence it appears, that in every system of logarithms, the logarithm of unity must be 0. If, on the other hand, we assume $a = r$, then we have the equation $r = r^A$, which is immediately satisfied by putting $A = 1$; therefore, the logarithm of the base, or radical number of every system, is necessarily unity.

If we suppose r and a to be each a positive number greater than unity, then A will be a positive number; for

if it be a negative we would have $a (= r^{-A} = \frac{1}{r^A})$, a pro-

per fraction, and at same time a number greater by hypothesis than unity, which is absurd. If, on the contrary, we suppose a a proper fraction, then A must necessarily be negative, otherwise r^A would be greater than unity, and $a (= r^A)$ also greater than unity, while by hypothesis it is a fraction less than unity, which is absurd. Therefore, in every system, the base of which exceeds unity, the logarithm of a whole or mixed number is always positive, but the logarithm of a proper fraction is always negative.

Because the logarithm of r is unity, that of r^n will be n ; therefore, the logarithm of any integral power of the radical number r will always be an integer.

Let r and r' denote bases of two different systems; and let A be the logarithm of a number, a , taken according to the first of these, and A' its logarithm according to the second. Then, because $a = r^A$, and $a = r'^{A'}$, it follows that $r^A = r'^{A'}$, and $r = r'^{\frac{A'}{A}}$. Let us now suppose that r'' is the base of a third system of logarithms, and R and R' ,

Nature of Logarithms.

Nature
of Loga-
rithms.

the logarithms of r and r' , taken according to this third system; then, because

$$r^R = r, \quad r'^{R'} = r';$$

we have $r^R R' = r'^{R'} R'$, $r^R R' = r'^{R'} R'$;

therefore $r^R = r'^{R'}$, and $r = r'^{\frac{R}{R'}}$; but we have already

found $r = r'^{\frac{A'}{A}}$, therefore $r'^{\frac{A'}{A}} = r'^{\frac{R}{R'}}$, and consequently

$$\frac{A'}{A} = \frac{R}{R'}, \text{ and } A : A' :: R' : R :: \frac{1}{R} : \frac{1}{R'}$$

Hence it appears, that the logarithm of a number, taken according to one system, has to its logarithm, taken according to any other system, a constant ratio, which is the same as that of the reciprocals of the logarithms of the radical numbers of those systems.

Let us next suppose that a and b are two numbers, and A and B their logarithms, taken according to the same system, and r the base of the system; then, because

$$r^A = a, \quad r^B = b;$$

we have $r^{AB} = a^B$, $r^{AB} = b^A$;

therefore $a^B = b^A$, and $a = b^{\frac{A}{B}}$. Now as r is not found in this equation, the value of the fraction $\frac{A}{B}$ depends only on a and b ; therefore, the logarithms of any two given numbers have the same ratio to each other in every system.

Having now explained the properties which belong to the logarithms of any system, we proceed to investigate general rules by which the number corresponding to any logarithm, and, on the contrary, the logarithm corresponding to any number, may be found the one from the other. And for this end let us denote any number whatever by y , and its logarithm by x , and put r as before for the base or radical number of the system; then, by the nature of logarithms,

$$y = r^x.$$

Put $r = 1 + a$, and let the expression $(1 + a)^x$ be expanded into a series by the binomial theorem; thus

$$y = 1 + xa + \frac{x(x-1)}{1 \cdot 2} a^2 + \frac{x(x-1)(x-2)}{1 \cdot 2 \cdot 3} a^3 + \frac{x(x-1)(x-2)(x-3)}{1 \cdot 2 \cdot 3 \cdot 4} a^4 + \&c.$$

Let this series, the terms of which are arranged according to the powers of a , be transformed into another, whose terms shall be arranged according to the powers of x ; and to effect this we must find the actual products of the factors which constitute the powers of a , and arrange the terms anew, as follows:

$$\begin{aligned} 1 &= 1, \\ xa &= + ax, \\ \frac{x(x-1)}{1 \cdot 2} a^2 &= -\frac{a^2}{2} x + \frac{a^2}{2} x^2, \\ \frac{x(x-1)(x-2)}{1 \cdot 2 \cdot 3} a^3 &= +\frac{a^3}{3} x - \frac{a^3}{2} x^2 + \frac{a^3}{6} x^3, \\ \frac{x(x-1)(x-2)(x-3)}{1 \cdot 2 \cdot 3 \cdot 4} a^4 &= -\frac{a^4}{4} x + \frac{11a^4}{24} x^2 - \frac{a^4}{4} x^3 + \frac{a^4}{24} x^4, \\ &\&c. \qquad \qquad \&c. \end{aligned}$$

so that adding into one sum the quantities on each side of the sign $=$, and recollecting that the sum of those on the left-hand side is equal to y , we have

$$y = r^x = \begin{cases} 1 \\ + (a - \frac{a^2}{2} + \frac{a^3}{3} - \frac{a^4}{4} + \&c.) x \\ + (\frac{a^2}{2} - \frac{a^3}{2} + \frac{11a^4}{24} - \&c.) x^2 \\ + (\frac{a^3}{6} - \frac{a^4}{4} + \&c.) x^3 \\ + (\frac{a^4}{24} - \&c.) x^4 \\ + \&c. \end{cases}$$

$$\text{Put } A = a - \frac{a^2}{2} + \frac{a^3}{3} - \frac{a^4}{4} + \&c.$$

$$A' = \frac{a^2}{2} - \frac{a^3}{2} + \frac{11a^4}{24} - \&c.$$

$$A'' = \frac{a^3}{6} - \frac{a^4}{4} + \&c.$$

$$A''' = \frac{a^4}{24} - \&c.$$

&c.

$$\text{then } r^x = 1 + Ax + A'x^2 + A''x^3 + A'''x^4 + \&c.$$

Next, to determine the law of connection of the quantities $A, A', A'', \&c.$ since the last equation is to hold good whatever be the value of the variable quantity, a similar equation may be formed with the same co-efficients, and having $x + z$ for its variable (z being any indefinite quantity); thus we have also

$$r^{x+z} = 1 + A(x+z) + A'(x+z)^2 + A''(x+z)^3 + \&c.$$

But $r^{x+z} = r^x \times r^z$, and since it has been shown that

$$r^x = 1 + Ax + A'x^2 + A''x^3 + A'''x^4 + \&c.$$

for the same reason

$$r^z = 1 + Az + A'z^2 + A''z^3 + A'''z^4 + \&c.$$

therefore the series

$$1 + A(x+z) + A'(x+z)^2 + A''(x+z)^3 + A'''(x+z)^4 + \&c.$$

is equal to the product of the two series

$$1 + Ax + A'x^2 + A''x^3 + A'''x^4 + \&c.$$

$$1 + Az + A'z^2 + A''z^3 + A'''z^4 + \&c.$$

That is, by the actual involution of the former and multiplication of the two latter,

$$\begin{aligned} & \left. \begin{aligned} 1 + Ax + A'x^2 + A''x^3 + A'''x^4 + \&c. \\ + Az + 2A'xz + 3A''x^2z + 4A'''x^3z + \&c. \\ + A'z^2 + 3A''xz^2 + 6A'''x^2z^2 + \&c. \\ + A''z^3 + 4A'''xz^3 + \&c. \\ + A'''z^4 + \&c. \end{aligned} \right\} = \\ & = \left\{ \begin{aligned} 1 + Ax + A'x^2 + A''x^3 + A'''x^4 + \&c. \\ + Az + A^2xz + AA'x^2z + AA''x^3z + \&c. \\ + A'z^2 + AA'xz^2 + A'A'x^2z^2 + \&c. \\ + A''z^3 + AA''xz^3 + \&c. \\ + A'''z^4 + \&c. \end{aligned} \right. \end{aligned}$$

Now the quantities $A, A', A'', \&c.$ being quite independent of x and z , the two sides of the equation can only be identical, upon the supposition that the co-efficients of like terms in each are equal; therefore, setting aside the first line of each side of the equation, because their terms are the same, and also the first term of the second line, for the same reason, let the co-efficients of the remaining terms be put equal to one another. Thus we have

$$\left. \begin{aligned} A^2 &= 2A'A' \\ AA' &= 3A'' \\ AA'' &= 4A''' \\ &\&c. \end{aligned} \right\} \text{ and hence we have } \begin{cases} A' = \frac{A^2}{1 \cdot 2} \\ A'' = \frac{A^3}{1 \cdot 2 \cdot 3} \\ A''' = \frac{A^4}{1 \cdot 2 \cdot 3 \cdot 4} \\ \&c. \end{cases}$$

Here the law of the co-efficients $A, A', A'', \&c.$ is obvious,

Construction
of Loga-
rithms

Construction of Logarithms. each being formed from the preceding by multiplying it by A, and dividing by the exponent of the power of A, which is thus formed. Let these values of A', A'', &c. be now substituted in the equation

$$y = r^x = 1 + Ax + A'x^2 + A''x^3 + \&c.$$

and it becomes

$$y = 1 + Ax + \frac{A^2}{1 \cdot 2}x^2 + \frac{A^3}{1 \cdot 2 \cdot 3}x^3 + \frac{A^4}{1 \cdot 2 \cdot 3 \cdot 4}x^4 + \&c.$$

Thus we have obtained a general formula expressing a number in terms of its logarithm and the base of the system, for we must recollect that since $a = r - 1$, the quantity A, which is equal to

$$a - \frac{a^2}{2} + \frac{a^3}{3} - \frac{a^4}{4} + \frac{a^5}{5} - \&c.$$

is otherwise expressed by

$$r - 1 - \frac{(r-1)^2}{2} + \frac{(r-1)^3}{3} - \frac{(r-1)^4}{4} + \frac{(r-1)^5}{5} - \&c.$$

where r denotes the base of the system.

If in the formula

$$r^x = 1 + Ax + \frac{A^2}{1 \cdot 2}x^2 + \frac{A^3}{1 \cdot 2 \cdot 3}x^3 + \frac{A^4}{1 \cdot 2 \cdot 3 \cdot 4}x^4 + \&c$$

we suppose $x = 1$, it becomes

$$r = 1 + A + \frac{A^2}{1 \cdot 2} + \frac{A^3}{1 \cdot 2 \cdot 3} + \frac{A^4}{1 \cdot 2 \cdot 3 \cdot 4} + \&c.$$

an equation which contains r only; but as r has been all along supposed an indeterminate quantity, this equation must be identical, that is, if, instead of A, its value, as expressed above in terms of r , were substituted, the equation would become $r = r$.

Again, let us suppose that $\frac{1}{A}$ is substituted instead of x in the general formula; thus it becomes

$$r^{\frac{1}{A}} = 1 + 1 + \frac{1}{1 \cdot 2} + \frac{1}{1 \cdot 2 \cdot 3} + \frac{1}{1 \cdot 2 \cdot 3 \cdot 4} + \&c.$$

Thus the quantity $r^{\frac{1}{A}}$, whatever be the value of r , is evidently equal to a constant number, which, as appears from the last equation, is equal to the value of r when $A = 1$. By adding together a sufficient number of terms of the last series, we find it nearly equal to

$$2.7182818284590452353602874.$$

If this be denoted by e , we have $r^{\frac{1}{A}} = e$, and $r = e^A$; hence, if the number e be considered as the base of a logarithmic system, the quantity A, namely,

$$r - 1 - \frac{(r-1)^2}{2} + \frac{(r-1)^3}{3} - \frac{(r-1)^4}{4} + \frac{(r-1)^5}{5} - \&c.$$

is the logarithm of r to the base e . But as r is not restricted here to any particular value, we may substitute y instead of it, keeping in mind that y denotes any number whatever, and x its logarithm; thus we have x the logarithm of y , expressed by the series

$$y - 1 - \frac{(y-1)^2}{2} + \frac{(y-1)^3}{3} - \frac{(y-1)^4}{4} + \frac{(y-1)^5}{5} - \&c.$$

supposing that the base of the system is the number we have expressed above by e .

We have now found a general formula for the logarithm of any number y , taken according to a particular system, namely, that which has the number e for its base. But it is easy from hence to find a formula, which shall apply to any system whatever. For it has been shown that the logarithms of the same number, taken according to two different systems, are to each other as the reciprocals of the

logarithms of the bases of the systems, these last logarithms being taken according to any system whatever, that is,

$$\log. y \text{ to base } e : \log. y \text{ to base } r :: \frac{1}{\log. e} : \frac{1}{\log. r};$$

hence we find

$$\log. y \text{ to base } r = \frac{\log. e}{\log. r} \times \log. y \text{ to base } e.$$

Let the value already found for the logarithm of y to base e be substituted in this equation, and it becomes

$$\log. y = x = \frac{\log. e}{\log. r} \left\{ y - 1 - \frac{(y-1)^2}{2} + \frac{(y-1)^3}{3} - \frac{(y-1)^4}{4} + \&c. \right\}$$

which is a general formula for the logarithm of any number whatever, to the base r . And it is to be recollected

that in the fraction $\frac{\log. e}{\log. r}$, which is a common multiplier to the series, the logarithms are to be taken according to the same base, which however may be any number whatever.

If in the above formula we suppose $r = e$, the multiplier $\frac{\log. e}{\log. r}$ will be unity, and the formula will become simply

$$\log. y = y - 1 - \frac{(y-1)^2}{2} + \frac{(y-1)^3}{3} - \frac{(y-1)^4}{4} + \&c.$$

as we have already remarked. Now this is the system which was adopted by Lord Napier; and although the logarithms which were computed according to this system, or upon the supposition that the radical number is 2.7182818, &c. have been called *hyperbolic logarithms*, because they happen to be proportional to certain hyperbolic spaces, yet, as the logarithms of every system have the same property, it is more proper to call them *Napierian logarithms*.

As the constant multiplier $\frac{\log. e}{\log. r}$, which occurs in the general formula for the logarithm of any number, is the only part of the formula which depends for its value upon the base of the system, it has been called by writers on logarithms the *modulus* of the system. If we suppose the logarithms taken to the base e , then the numerator, viz. $\log. e$, will be unity, and the denominator will be the Napierian logarithm of r . If however we suppose the logarithms taken to the base r , then the numerator will be $\log. e$ to base r ; and the denominator will be unity, so that the *modulus* of any system whose base is r , is the reciprocal of the Napierian logarithm of that base; or it is the logarithm of the number e (the base of the Napierian system) to the base r .

In the Napierian system, the *modulus* is unity, and hence the logarithms of this system are more easily computed than those of any other. It was, however, soon found that a system whose base should be the same as the root of the scale of the arithmetical notation, viz. the number 10, would be the most convenient of any in practice; and accordingly such a system was actually constructed by Mr Briggs. This is the only one now in common use, and is called *Briggs's system*, also the *common system* of logarithms. The *modulus* of this system therefore is the reciprocal of the Napierian logarithm of 10, viz. .43429448, which is the common logarithm of $e = 2.7182818$, &c. the base of the Napierian system. We shall in future denote this *modulus* by M; so that the formula expressing the common logarithm of any number y will be

$$\log. y = M \left\{ 1 - y - \frac{(1-y)^2}{2} + \frac{(1-y)^3}{3} - \frac{(1-y)^4}{4} + \&c. \right\}$$

If the number y , whose logarithm is required, be very near

Construction of Logarithms. to unity, so that $1 - y$ is a small quantity, then the logarithm may be found from this formula with great ease, because the series will converge very rapidly. If, however, $1 - y$ be greater than unity, the series, instead of converging, will diverge, so as to be, in its present form, of no use.

It may, however, be transformed into another, which shall converge in every case, by substituting in it $\sqrt[n]{y}$ instead of y , and observing that $\log. (\sqrt[n]{y}) = \frac{\log. y}{n}$;

it thus becomes

$\log. y = nM \left\{ \sqrt[n]{y} - 1 - \frac{1}{2}(\sqrt[n]{y} - 1)^2 + \frac{1}{3}(\sqrt[n]{y} - 1)^3 - \&c \right\}$ where n may denote any number, positive or negative. But whatever be the number y , we can always take n , such, that $\sqrt[n]{y}$ shall be as near to 1 as we please; therefore, by this last formula, we can always find the logarithm of y to any degree of accuracy.

If n be taken negative, then $\sqrt[n]{y} = \frac{1}{\sqrt[n]{y}}$, and the series for $\log. y$ becomes, by changing the signs,

$$\log. y = nM \left\{ 1 - \frac{1}{\sqrt[n]{y}} + \frac{1}{2} \left(1 - \frac{1}{\sqrt[n]{y}} \right)^2 + \frac{1}{3} \left(1 - \frac{1}{\sqrt[n]{y}} \right)^3 + \&c. \right\}$$

where all the terms are positive. Thus we have it in our power to express the value of y , either by a series which shall have its terms all positive, or by one which shall have its terms alternately positive and negative: for it is evident that if y be greater than unity, $\sqrt[n]{y}$ will also be greater than unity, and *vice versa*; but the differences will be so much the smaller as n the exponent of the root is greater; therefore $\sqrt[n]{y} - 1$ will be positive in the first case, and negative in the second.

Because Nap. $\log. 10 = \frac{1}{M}$, we have by the two last formulas

$$\frac{1}{M} = n \left\{ \sqrt[n]{10} - 1 - \frac{1}{2}(\sqrt[n]{10} - 1)^2 + \frac{1}{3}(\sqrt[n]{10} - 1)^3 - \&c. \right\}$$

also

$$\frac{1}{M} = n \left\{ 1 - \frac{1}{\sqrt[n]{10}} + \frac{1}{2} \left(1 - \frac{1}{\sqrt[n]{10}} \right)^2 + \frac{1}{3} \left(1 - \frac{1}{\sqrt[n]{10}} \right)^3 + \&c. \right\}$$

It is evident, that by giving to $\sqrt[n]{y}$ such a value that $\sqrt[n]{y} - 1$ is a fraction less than unity, we render both the series for the value of $\log. y$ converging; for then the expression $1 - \frac{1}{\sqrt[n]{y}}$ will also be less than unity, seeing

it is equal $\frac{\sqrt[n]{y} - 1}{\sqrt[n]{y}}$. Therefore, in the first series, the

second and third terms (taken together as one term) constitute a negative quantity; and as the same is also true of the fourth and fifth, and so on, the amount of all the terms after the first is a negative quantity, or one which is to be subtracted from the first, to obtain the value of $\log. y$. Hence

$$\log. y < nM(\sqrt[n]{y} - 1).$$

And since, on the contrary, the terms of the second series are all positive, the amount of all the terms after the first is a positive quantity, or one which must be added to the first to give the value of $\log. y$; so that

$$\log. y > nM \left(1 - \frac{1}{\sqrt[n]{y}} \right).$$

Thus we have two limits to the value of the logarithm

of y , which, by taking the number n sufficiently great may come as near to each other as we please.

In like manner we find two limits to the value of the reciprocal to the modulus, viz.

$$\frac{1}{M} < n(\sqrt[n]{10} - 1), \quad \frac{1}{M} > n \left(1 - \frac{1}{\sqrt[n]{10}} \right).$$

It is evident that the difference between the two limits of $\log. y$, is

$$nM \left\{ (\sqrt[n]{y} - 1) - \left(1 - \frac{1}{\sqrt[n]{y}} \right) \right\},$$

therefore, if we take either the one or the other of the two preceding expressions for $\log. y$, the error in excess or defect is necessarily less than this quantity.

By these formulæ we may depend upon having the logarithm of any number true to n figures, if we give to n such a value that the root $\sqrt[n]{y}$ shall have m ciphers between the decimal point and the first significant figure on the right. So that in general, as the error is the smaller as n the exponent of the root is greater, it may be neglected when n is taken indefinitely great; and this being the case, we may conclude that either of these expressions,

$$nM(\sqrt[n]{y} - 1), \quad nM \left(1 - \frac{1}{\sqrt[n]{y}} \right)$$

is the accurate value of $\log. y$.

The best manner of applying the preceding formula is to take some power of the number 2 for n ; for by doing so, the root $\sqrt[n]{y}$ may be found by a repetition of extractions of the square root only. It was in this way that Briggs calculated the first logarithms; and he remarked, that if in performing the successive extractions of the square root, he at last obtained twice as many decimal places as there were ciphers after the decimal point, the integer before it being unity, then the decimal part of this root was exactly the half of that which went before; so that the decimal parts of the two roots were to each other in the same proportion as their logarithms: now this is an evident consequence of the preceding formula.

To give an example of the application of the formula, let it be required to find the numerical value of M , the modulus of the common system of logarithms, which, as it is the reciprocal of the Napierian logarithm of 10, is

$$\frac{1}{n} \times \frac{1}{\sqrt[n]{10} - 1} \text{ nearly,}$$

when n is some very great number. Let us suppose $n = 2^{60} = 8^{20}$; then, dividing unity by 8, and this result again by 8, and so on, we shall, after 20 divisions, have

$$\frac{1}{n} \text{ or } \frac{1}{8^{20}}, \text{ equal to}$$

$$0.00000000000000000000000086736173798840854.$$

Also, by extracting the square root of 10, and the square root of this result, and so on, after performing 60 extractions we shall find $\sqrt[n]{10}$ equal to

$$1.0000000000000000000000001971742081255052703251.$$

Therefore, $\frac{1}{n} \times \frac{1}{\sqrt[n]{10} - 1}$, or M is equal to

$$\frac{86736173798840854}{199717420812550527} = 0.4342944819.$$

As a second example, let it be required to find by the same formula the logarithm of 3, which is nearly

$$nM(\sqrt[n]{3} - 1) = \frac{n(\sqrt[n]{3} - 1)}{n(\sqrt[n]{10} - 1)} = \frac{\sqrt[n]{3} - 1}{\sqrt[n]{10} - 1},$$

n being as before a very great number. Let us suppose also in this case that $n = 2^{60}$; then after 60 extractions of the square root we have $\sqrt[n]{3}$ equal to

$$1.00000000000000000000000095289476407458932.$$

Construc- Therefore, taking the value of $\sqrt[n]{10}$ as found in last ex-
tion of Lo- ample, we have
garithms.

$$\log. 3 = \frac{\sqrt[n]{3} - 1}{\sqrt[n]{10} - 1} = \frac{95289426407458932}{199717420812550527} = .477121254719662.$$

This method of computing logarithms is evidently attended with great labour, on account of the number of extractions of roots which it requires to obtain a result true to a moderate number of places of figures. But the two series which we have given serve to simplify and complete it. For, whatever be the number y , it is only necessary to proceed with the extractions of the square root, till we have obtained for $\sqrt[n]{y}$ a value which is unity followed by a decimal fraction; and then $\sqrt[n]{y} - 1$ being a fraction, its powers will also be fractions so much the smaller as their exponents are greater; thus a certain number of terms of the series will express the logarithm to as many decimal places as may be required.

There are yet other artifices by which the series $\log. y = M \{ y - 1 - \frac{1}{2}(y-1)^2 + \frac{1}{3}(y-1)^3 - \frac{1}{4}(y-1)^4 + \&c. \}$ may be transformed into others which shall always converge, and in particular the following. Let $1 + u$ be substituted in the series for y ; then it becomes

$$\log. (1+u) = M \left(u - \frac{u^2}{2} + \frac{u^3}{3} - \frac{u^4}{4} + \frac{u^5}{5} - \&c. \right)$$

In like manner, if $1 - u$ be substituted for y , we have

$$\log. (1-u) = M \left(-u - \frac{u^2}{2} - \frac{u^3}{3} - \frac{u^4}{4} - \frac{u^5}{5} - \&c. \right)$$

Let the latter equation be subtracted from the former; and since $\log. (1+u) - \log. (1-u)$, is equal to $\log. \frac{1+u}{1-u}$; we shall have

$$\log. \frac{1+u}{1-u} = 2M \left\{ u + \frac{u^3}{3} + \frac{u^5}{5} + \frac{u^7}{7} + \&c. \right\},$$

which series, by substituting z for $\frac{1+u}{1-u}$, and consequently $\frac{z-1}{z+1}$ for u , will be otherwise expressed thus,

$$\log. z = 2M \left\{ \frac{z-1}{z+1} + \frac{1}{3} \left(\frac{z-1}{z+1} \right)^3 + \frac{1}{5} \left(\frac{z-1}{z+1} \right)^5 + \&c. \right\};$$

which is not only simple, but has also the property of converging in every case.

As an example of the utility of this formula, we shall employ it to compute the Napierian logarithm of 2, which will be

$$2 \left(\frac{1}{3} + \frac{1}{3 \cdot 3^3} + \frac{1}{5 \cdot 3^5} + \frac{1}{7 \cdot 3^7} + \frac{1}{9 \cdot 3^9} + \&c. \right) = A + \frac{1}{3}B + \frac{1}{5}C + \frac{1}{7}D + \frac{1}{9}E + \&c.$$

where A is put for $\frac{2}{3}$, B for $\frac{2}{3^3} = \frac{A}{9}$, C for $\frac{2}{3^5} = \frac{B}{9}$, D for $\frac{2}{3^7} = \frac{C}{9}$, &c. The calculation will be as follows:

$$\begin{array}{ll} A = & .666666666666 \\ B = \frac{1}{3} A = & .074074074074 \\ C = \frac{1}{5} B = & .008230452674 \\ D = \frac{1}{7} C = & .000914494742 \\ E = \frac{1}{9} D = & .000101610527 \\ F = \frac{1}{11} E = & .000011290059 \\ G = \frac{1}{13} F = & .000001254451 \\ H = \frac{1}{15} G = & .000000139383 \\ I = \frac{1}{17} H = & .000000015487 \\ K = \frac{1}{19} I = & .000000001721 \\ L = \frac{1}{21} K = & .000000000191 \\ M = \frac{1}{23} L = & .000000000021 \end{array}$$

$$\begin{array}{ll} A = & .666666666666 \\ \frac{1}{3} B = & .024691358025 \\ \frac{1}{5} C = & .001646090535 \\ \frac{1}{7} D = & .000130642106 \\ \frac{1}{9} E = & .000011290056 \\ \frac{1}{11} F = & .000001026369 \\ \frac{1}{13} G = & .000000096496 \\ \frac{1}{15} H = & .000000009292 \\ \frac{1}{17} I = & .000000000911 \\ \frac{1}{19} K = & .000000000091 \\ \frac{1}{21} L = & .000000000001 \end{array}$$

Construc-
tion of Lo-
garithms.

$$\text{Nap. log. } 2 = .693147180561$$

Thus, by a very easy calculation, we have obtained the Napierian logarithm of 2 true to the first ten places of figures; the accurate value, as far as the 12th place, being 0.693147180560.

If this very simple process, by which we have found the logarithm of 2 (the whole of which is here actually put down), be compared with the laborious calculations which must have been performed to have found the same logarithm by the method explained in the beginning of this section, the great superiority of this method to the other, and even to the second method, by which we found the value of M, and the logarithm of 3, must be very apparent.

In the same manner as we have found the logarithm of 2, we may find those of 3, 5, &c. In computing the logarithm of 3, the series would converge by the powers of the fraction $\frac{3-1}{3+1} = \frac{1}{2}$, and in computing the logarithm of 5 it

would converge by the powers of $\frac{5-1}{5+1} = \frac{2}{3}$; but in each

of these cases the series would converge slower, and of course the labour would be greater than in computing the logarithm of 2. And if the number whose logarithm was required was still more considerable; as, for example, 199, the series would converge so slow as to be useless.

We may however avoid this inconvenience by again transforming this last formula into another which shall express the logarithm of any number by means of a series, and a logarithm supposed to be previously known. To effect this new transformation, let $\frac{1+u}{1-u} = 1 + \frac{z}{n}$, and

consequently $u = \frac{z}{2n+z}$, these values being substituted in

the formula, $\log. \frac{1+u}{1-u} = 2M \left(u + \frac{u^3}{3} + \frac{u^5}{5} + \frac{u^7}{7} + \&c. \right)$

we have $\log. \left(1 + \frac{z}{n} \right)$ equal to

$$2M \left\{ \frac{z}{2n+z} + \frac{1}{3} \left(\frac{z}{2n+z} \right)^3 + \frac{1}{5} \left(\frac{z}{2n+z} \right)^5 + \&c. \right\}$$

but $\log. \left(1 + \frac{z}{n} \right) = \log. \frac{n+z}{n} = \log. (n+z) - \log. n$,

therefore, $\log. (n+z) = \log. n +$

$$2M \left\{ \frac{z}{2n+z} + \frac{1}{3} \left(\frac{z}{2n+z} \right)^3 + \frac{1}{5} \left(\frac{z}{2n+z} \right)^5 + \&c. \right\}$$

By the assistance of this formula, and the known properties of logarithms, we may proceed calculating the logarithm of one number from that of another as follows.

To find the Napierian logarithm of 3 from that of 2, already found. We have here $n = 2$, $z = 1$, and $\frac{z}{2n+z} = \frac{1}{3}$.

Therefore the logarithm of 3 is

$$\begin{aligned} \log. 2 + 2 \left(\frac{1}{3} + \frac{1}{3 \cdot 3^3} + \frac{1}{5 \cdot 3^5} + \frac{1}{7 \cdot 3^7} + \&c. \right) \\ = \log. 2 + A + \frac{1}{3}B + \frac{1}{5}C + \frac{1}{7}D + \frac{1}{9}E + \&c. \end{aligned}$$

Construction of Logarithms. where A is put for $\frac{1}{2}$, B for $\frac{1}{25}$, C for $\frac{1}{25}$, and so on.

The calculation may stand thus :

$$\begin{aligned} A &= \cdot 400000000000 \\ B = \frac{1}{25} A &= \cdot 016000000000 \\ C = \frac{1}{25} B &= \cdot 000640000000 \\ D = \frac{1}{25} C &= \cdot 000025600000 \\ E = \frac{1}{25} D &= \cdot 000001024000 \\ F = \frac{1}{25} E &= \cdot 000000040960 \\ G = \frac{1}{25} F &= \cdot 000000001638 \\ H = \frac{1}{25} G &= \cdot 000000000066 \end{aligned}$$

$$\begin{aligned} A &= \cdot 400000000000 \\ \frac{1}{2} B &= \cdot 005333333333 \\ \frac{1}{3} C &= \cdot 000128000000 \\ \frac{1}{4} D &= \cdot 000003657143 \\ \frac{1}{5} E &= \cdot 000000113778 \\ \frac{1}{6} F &= \cdot 000000003724 \\ \frac{1}{7} G &= \cdot 000000000126 \\ \frac{1}{8} H &= \cdot 000000000034 \end{aligned}$$

$$\begin{aligned} &\cdot 405465108108 \\ \text{Nap. log. 2} &= \cdot 693147180551 \end{aligned}$$

$$\text{Nap. log. 3} = 1\cdot 098612288659$$

This logarithm is true to 10 decimal places, the accurate value to 12 figures being 1·098612288668, which would have been our result had the correct value of log. 2, viz. ·693147180560 been employed.

The Napierian logarithm of 4 is immediately had from that of 2 by considering that as $4 = 2^2$, therefore $\log. 4 = \log. 2 + \log. 2$.

$$\text{Nap. log. 2} = \cdot 693147180551$$

$$\text{Nap. log. 4} = 1\cdot 386294361102$$

This is also true to 10 places besides the integer.

To find the Napierian logarithm of 5, from that of 4 ;

we have $n = 4$, $z = 1$, and $\frac{z}{2n+1} = \frac{1}{9}$, therefore the logarithm of 5 is expressed by

$$\log. 4 + 2 \left(\frac{1}{9} + \frac{1}{3 \cdot 9^3} + \frac{1}{5 \cdot 9^5} + \frac{1}{7 \cdot 9^7} + \&c. \right)$$

$$\log. 4 + A + \frac{1}{2} B + \frac{1}{3} C + \frac{1}{4} D + \&c.$$

where $A = \frac{1}{9}$, $B = \frac{1}{81} A$, $C = \frac{1}{81} B$, &c.

The calculation.

$$\begin{aligned} A &= \cdot 222222222222 \\ B = \frac{1}{81} A &= \cdot 002743484225 \\ C = \frac{1}{81} B &= \cdot 000033870176 \\ D = \frac{1}{81} C &= \cdot 000000418150 \\ E = \frac{1}{81} D &= \cdot 000000005162 \\ F = \frac{1}{81} E &= \cdot 000000000064 \end{aligned}$$

$$\begin{aligned} A &= \cdot 222222222222 \\ \frac{1}{2} B &= \cdot 000914494742 \\ \frac{1}{3} C &= \cdot 000006774035 \\ \frac{1}{4} D &= \cdot 000000059736 \\ \frac{1}{5} E &= \cdot 000000000574 \\ \frac{1}{6} F &= \cdot 000000000006 \end{aligned}$$

$$\begin{aligned} &\cdot 223143551315 \\ \text{Nap. log. 4} &= 1\cdot 386294361102 \end{aligned}$$

$$\text{Nap. log. 5} = 1\cdot 609437912417$$

This result is also correct to the first ten places.

The logarithm of 6 is found from those of 2 and 3, because $6 = 2 \times 3$, therefore $\log. 6 = \log. 2 + \log. 3$.

$$\begin{aligned} \text{Nap. log. 2} &= 0\cdot 693147180551 \\ \text{Nap. log. 3} &= 1\cdot 098612288659 \end{aligned}$$

$$\text{Nap. log. 6} = 1\cdot 791759469210$$

This result is correct as far as the tenth decimal place.

We might find the logarithm of 7 from that of 6, that is, from the logarithms of 3 and 2, in the same manner as we have found the logarithms of 5 and 3 ; but it may be more readily found from the logarithms of 2 and 5 thus.

$$\text{Because } \frac{2 \times 5^2}{7^2} = \frac{50}{49}, \text{ therefore } \log. 2 + 2 \log. 5 -$$

$$2 \log. 7 = \log. \frac{50}{49}, \text{ and consequently}$$

$$\log. 7 = \frac{1}{2} \log. 2 + \log. 5 - \frac{1}{2} \log. \frac{50}{49}.$$

Now the logarithm of $\frac{50}{49}$ may be readily obtained from

$$\log. z = 2M \left\{ \frac{z-1}{z+1} + \frac{1}{3} \left(\frac{z-1}{z+1} \right)^3 + \frac{1}{5} \left(\frac{z-1}{z+1} \right)^5 + \&c. \right\}$$

For, substituting $\frac{50}{49}$ for z , the formula gives

$$\begin{aligned} \text{Nap. log. } \frac{50}{49} &= 2 \left(\frac{1}{99} + \frac{1}{3 \cdot 99^3} + \frac{1}{5 \cdot 99^5} + \&c. \right) \\ &= A + \frac{1}{2} B + \frac{1}{3} C + \&c. \end{aligned}$$

where $A = \frac{2}{9 \cdot 11}$, $B = \frac{2}{9^3 \cdot 11^3}$, $C = \frac{2}{9^5 \cdot 11^5}$, &c. This series converges with great rapidity, and a few of its terms will be sufficient to give the logarithm of 7, as appears from the following operation.

$$A = \cdot 020202020202$$

$$B = \frac{1}{9^3 \cdot 11^3} A = \cdot 000002061220$$

$$C = \frac{1}{9^5 \cdot 11^5} B = \cdot 000000000210$$

$$A = \cdot 020202020202$$

$$\frac{1}{2} B = \cdot 000000687073$$

$$\frac{1}{3} C = \cdot 000000000042$$

$$\text{Nap. log. } \frac{50}{49} = \cdot 020202707317$$

$$\frac{1}{2} \log. 2 = 0\cdot 346573590275$$

$$\log. 5 = 1\cdot 609437912417$$

$$1\cdot 956011502692$$

$$\frac{1}{2} \log. \frac{50}{49} = 0\cdot 010101353658$$

$$\text{Nap. log. 7} = 1\cdot 945910149034$$

This logarithm, like those we found before, is correct in the first ten decimal places.

The logarithms of 8, 9, and 10 are immediately obtained from those of 2, 3, and 5, as follows :

$$\text{Nap. log. 2} = 0\cdot 693147180551$$

$$\text{Nap. log. 8} = 2\cdot 079441541653$$

$$\text{Nap. log. 3} = 1\cdot 098612288659$$

$$\text{Nap. log. 9} = 2\cdot 197224577318$$

$$\text{Nap. log. 2} = 0\cdot 693147180551$$

$$\text{Nap. log. 5} = 1\cdot 609437912417$$

$$\text{Nap. log. 10} = 2\cdot 302585092968$$

Construction of Logarithms.

Construction of Logarithms.

Thus by a few calculations we have found the Napierian logarithms of the first ten numbers, each true to ten decimal places; and since the Napierian logarithm of 10 is now known, the *modulus* of the common system, which is the reciprocal of that logarithm, will also be known, and will be

$$\frac{1}{2.302585092968} = .4342944819.$$

The common logarithms of the first ten numbers may now be found from the Napierian logarithms by multiplying each of the latter by the *modulus*, or dividing by its reciprocal, that is, by the Napierian logarithm of 10. And as the *modulus* of the common system is so important an element in the theory of logarithms, we shall give its value, together with that of its reciprocal, as far as the 30th decimal place.

$$M = .434294481903251827651128918916$$

$$\frac{1}{M} = 2.302585092994045684017991454684$$

The formulæ already given are sufficient for finding the logarithms of all numbers whatever throughout the table; but there are yet others which may often be applied with great advantage, and we shall now investigate some of these.

Because

$$\log. z = 2M \left\{ \frac{z-1}{z+1} + \frac{1}{3} \left(\frac{z-1}{z+1} \right)^3 + \frac{1}{5} \left(\frac{z-1}{z+1} \right)^5 + \&c. \right\}$$

If we now suppose

$$z = \frac{n^2}{n^2-1} = \frac{n^2}{(n-1)(n+1)},$$

so that $\frac{z-1}{z+1} = \frac{1}{2n^2-1}$, then the formula becomes

$$\log. \frac{n^2}{(n-1)(n+1)} = 2M \left\{ \frac{1}{2n^2-1} + \frac{1}{3} \left(\frac{1}{2n^2-1} \right)^3 + \frac{1}{5} \left(\frac{1}{2n^2-1} \right)^5 + \&c. \right\}$$

But $\log. \frac{n^2}{(n-1)(n+1)} = 2 \log. n - \log. (n-1) - \log. (n+1)$, therefore, putting N for the series

$$2M \left\{ \frac{1}{2n^2-1} + \frac{1}{3} \left(\frac{1}{2n^2-1} \right)^3 + \frac{1}{5} \left(\frac{1}{2n^2-1} \right)^5 + \&c. \right\}$$

we have this formula,

$2 \log. n - \log. (n-1) - \log. (n+1) = N$; and hence, as often as we have the logarithms of any two of three numbers whose common difference is unity, the logarithm of the remaining number may be found. Example: Given $\log. 9 = 0.95424250943$, $\log. 10 = 1$; to find the common logarithm of 11.

Here we have $n = 10$, so that the formula gives in this case $2 \log. 10 - \log. 9 - \log. 11 = N$, and hence we have

$$\log. 11 = 2 \log. 10 - \log. 9 - N,$$

$$\text{where } N = \frac{2M}{199} + \frac{2M}{3 \cdot 199^3} + \&c.$$

$$M \text{ being } .43429448190.$$

Calculation of N .

$$A = \frac{2M}{199} = .00436476866$$

$$B = \frac{A}{3 \cdot 199^2} = .00000003674$$

$$N = 0.00436480540$$

$$\log. 9 = 0.95424250943$$

$$\log. 9 + N = 0.95860731483$$

$$2 \log. 10 = 2.00000000000$$

$$\log. 11 = 1.04139268517$$

Here the series expressed by N converges very fast, so that two of its terms are sufficient to give the logarithm true to 10 places of decimals. But the logarithm of 11 may be expressed by the logarithms of smaller numbers, and a series which converges still more rapidly, by the following artifice, which will apply also to some other numbers. Because the numbers 98, 99, and 100 are the products of numbers, the greatest of which is 11, for $98 = 2 \times 7^2$, $99 = 9 \times 11$, and $100 = 10 \times 10$, it follows that if we have an equation composed of terms which are the logarithms of these three numbers, it may be resolved into another, the terms of which shall be the logarithms of the number 11 and other smaller numbers. Now by the preceding formula, if we put 99 for n , we have

$$2 \log. 99 - \log. 98 - \log. 100 = N,$$

that is, substituting $\log. 9 + \log. 11$ for $\log. 99$, $\log. 2 + 2 \log. 7$ for $\log. 98$, and $2 \log. 10$ for $\log. 100$,

$$2 \log. 9 + 2 \log. 11 - \log. 2 - 2 \log. 7 - 2 \log. 10 = N,$$

and hence by transposition, &c.

$$\log. 11 = \frac{1}{2} N + \frac{1}{2} \log. 2 + \log. 7 - \log. 9 + \log. 10;$$

and in this equation

$$N = \frac{2M}{19601} + \frac{1}{3} \frac{2M}{19601^3} + \&c.$$

The first term alone of this series is sufficient to give the logarithm of 11 true to 14 places.

Another formula, by which the logarithm of a number is expressed by the logarithms of other numbers and a series, may be found as follows.

Resuming the formula

$$\log. z = 2M \left\{ \frac{z-1}{z+1} + \frac{1}{3} \left(\frac{z-1}{z+1} \right)^3 + \frac{1}{5} \left(\frac{z-1}{z+1} \right)^5 + \&c. \right\}$$

$$\text{put } z = \frac{(n-1)^2(n+2)}{(n-2)(n+1)^2} = \frac{n^3-3n+2}{n^3-3n-2},$$

$$\text{then } \frac{z-1}{z+1} = \frac{2}{n^3-3n}.$$

Let these values of z , and $\frac{z-1}{z+1}$, be substituted in the

formula, and it becomes

$$\log. \frac{(n-1)^2(n+2)}{(n-2)(n+1)^2} = 2M \left\{ \frac{2}{n^3-3n} + \frac{1}{3} \left(\frac{2}{n^3-3n} \right)^3 + \&c. \right\}$$

But the quantity on the left-hand side of this equation is manifestly equal to $2 \log. (n-1) + \log. (n+2) - \log. (n-2) - 2 \log. (n+1)$; therefore, putting P for the series,

$$2M \left\{ \frac{2}{n^3-3n} + \frac{1}{3} \left(\frac{2}{n^3-3n} \right)^3 + \frac{1}{5} \left(\frac{2}{n^3-3n} \right)^5 + \&c. \right\}$$

we have this formula,

$$\log. (n+2) + 2 \log. (n-1) - \log. (n-2) - 2 \log. (n+1) = P.$$

By this formula we may find, with great facility, the logarithm of any one of the four numbers $n-2$, $n-1$, $n+1$, $n+2$, having the logarithms of the other three. We may also employ it in the calculation of logarithms, as in the following example. Let the numbers 5, 6, 7, 8, be substituted successively in the formula; then, observing that $\log. 6 = \log. 2 + \log. 3$, and $\log. 8 = 3 \log. 2$, we have these four equations,

$$\log. 7 + 2 \log. 2 - 3 \log. 3 = \frac{2M}{55} + \frac{2M}{3 \cdot 55^3} + \&c.$$

$$-2 \log. 7 + \log. 2 + 2 \log. 5 = \frac{2M}{99} + \frac{2M}{3 \cdot 99^3} + \&c.$$

$$4 \log. 3 - 4 \log. 2 - \log. 5 = \frac{2M}{161} + \frac{2M}{3 \cdot 161^3} + \&c.$$

$$\log. 5 - 5 \log. 3 + 2 \log. 7 = \frac{2M}{244} + \frac{2M}{3 \cdot 244^3} + \&c.$$

Let $\log. 2$, $\log. 3$, $\log. 5$, and $\log. 7$, be now considered as

Construction of Logarithms. four unknown quantities, and by resolving those equations in the usual manner, the logarithms may be determined. Resuming once more the formula

$$\log. z = 2M \left\{ \frac{z-1}{z+1} + \frac{1}{3} \left(\frac{z-1}{z+1} \right)^3 + \&c. \right\}$$

let $\frac{n^2(n+5)(n-5)}{(n+3)(n-3)(n+4)(n-4)}$ be substituted in it

instead of z , then, by this substitution, $\frac{z-1}{z+1}$ will become

$$\frac{-72}{n^4-25n^2+72}, \text{ and the formula will be transformed to}$$

$$\log. \frac{n^2(n+5)(n-5)}{(n+3)(n-3)(n+4)(n-4)} = -2M \left\{ \frac{72}{n^4-25n^2+72} + \frac{1}{3} \left(\frac{72}{n^4-25n^2+72} \right)^3 + \&c. \right\}$$

Hence, putting the latter side of this equation equal to Q , we have this formula,

$$2 \log. n + \log. (n+5) + \log. (n-5) - \log. (n+3) - \log. (n-3) - \log. (n+4) - \log. (n-4) + Q = 0$$

which may be applied in the calculation of logarithms in the same manner as the former.

But when it is required to find the logarithm of a higher number, as, for example, 1231, we may proceed as follows.

$$\begin{aligned} \log. 1231 &= \log. (1230 + 1) = \log. \left\{ 1230 \left(1 + \frac{1}{1230} \right) \right\} \\ &= \log. 1230 + \log. \left(1 + \frac{1}{1230} \right). \end{aligned}$$

Again, $\log. 1230 = \log. 2 + \log. 5 + \log. 123$, and $\log.$

$$123 = \log. \left\{ 120 \left(1 + \frac{1}{40} \right) \right\} = \log. 120 + \log. \left(1 + \frac{1}{40} \right),$$

$\log. 120 = \log. (2^3 \times 3 \times 5) = 3 \log. 2 + \log. 3 + \log. 5$. Therefore $\log. 1231 = 4 \log. 2 + \log. 3 + 2 \log. 5 +$

$$\log. \left(1 + \frac{1}{40} \right) + \log. \left(1 + \frac{1}{1230} \right)$$

Thus the logarithm of the proposed number is expressed by the logarithms of 2, 3, 5, and the logarithms of

$1 + \frac{1}{40}$, $1 + \frac{1}{1230}$, all of which may be easily found by the formulæ already delivered.

Trigonometrical canon.

III.—NATURE AND CALCULATION OF SINES, TANGENTS, &c.

The trigonometrical formulæ given in the *Arithmetic of Sines* (See ALGEBRA) contain the principles requisite for constructing tables in which the lengths of the sines, cosines, tangents, cotangents, secants, and cosecants of given angles, are exhibited for every degree, minute, and second of space of the quadrant. Such tables are known as *Trigonometrical Canons*. It is evident that such tables, when accurately computed, are invaluable, and will prevent the labour and trouble of calculating afresh, on every new occasion, the sine, cosine, &c., of any angle that may be required.

Trigonometrical Canons are generally calculated to a radius unity, or 1; but when this is the case, all the results are multiplied by 10,000, or any high power of 10, in order to avoid printing cyphers to the immediate right of the decimal point of the sines of all small angles.

Since the length of the semi-circumference of a circle has been approximated to, and found to be $\pi = 3.1415926535897932$ when radius = 1; and since the number of degrees in the semi-perimeter is $180^\circ = 10800'$; hence $1'$ of space = $1'$ of an arc = 0.000290888204 . Now,

since the small angle of $1'$ is subtended by an arc of the same magnitude, the sine of $1'$ will also be a small quantity, and may be regarded as equal to the arc. Thus the sine $1' =$ length of an arc of $1' = 0.000290888204$. In this manner the sine of $1'$ may be determined, but more legitimately from the formula of $\cos 2A = 2 \cos^2 A - 1$.

$\therefore \cos A = \sqrt{\frac{1}{2}(1 + \cos 2A)}$, when A not $> 90^\circ$; and since this is true whatever the angle A be, it is true when for A we write $\frac{A}{2}$. Hence,

$$\cos \frac{A}{2} = \sqrt{\frac{1}{2}(1 + \cos A)}; \cos \frac{A}{2^2} = \sqrt{\frac{1}{2}\left(1 + \cos \frac{A}{2}\right)};$$

$$\cos \frac{A}{2^3} = \sqrt{\frac{1}{2}\left(1 + \cos \frac{A}{2^2}\right)}; \cos \frac{A}{2^4} = \sqrt{\frac{1}{2}\left(1 + \cos \frac{A}{2^3}\right)};$$

$$\&c. = \&c. \quad \&c. = \&c.$$

$$\cos \frac{A}{2^{11}} = \sqrt{\frac{1}{2}\left(1 + \cos \frac{A}{2^{10}}\right)}$$

Let A receive a particular value, as 30° ; then $\cos 2A = \cos 60^\circ = \frac{1}{2}$. Wherefore,

$$\cos 30^\circ = \sqrt{\frac{1}{2}(1 + \cos 60^\circ)} = \sqrt{\frac{1}{2}\left(1 + \frac{1}{2}\right)} = \frac{\sqrt{3}}{2}$$

$$= 0.8660254;$$

$$\begin{aligned} \cos 15^\circ &= \sqrt{\frac{1}{2}(1 + \cos 30^\circ)} = \sqrt{\frac{1}{2}(1 + 0.8660254)} \\ &= 0.9659258; \end{aligned}$$

$$\begin{aligned} \cos 7^\circ 30' &= \sqrt{\frac{1}{2}(1 + \cos 15^\circ)} = \sqrt{\frac{1}{2}(1 + 0.9659258)} \\ &= 0.9914449; \end{aligned}$$

$$\&c. = \&c. \quad = \quad \&c.$$

If now we proceed in this manner and compute eleven bisections of the angle 30° ; that is, $\frac{30^\circ}{2^{11}}$, we shall at last

$$\text{come to } \cos \frac{30^\circ}{2^{11}} = \sqrt{\frac{1}{2}\left(1 + \cos \frac{30^\circ}{2^{10}}\right)}, \text{ or}$$

$$\cos \frac{30 \times 60 \times 1'}{2^{11}} = \cos \frac{225}{256} \times 1' = \cos 52''.734375;$$

$\therefore \cos 52''.734375 = 0.99999996782$, which is a very little greater than the cosine of $1'$;

$$\begin{aligned} \therefore \sin \frac{30^\circ}{2^{11}} &= \sin 52''.734375 = \sqrt{1 - \cos^2 \frac{30^\circ}{2^{11}}} \\ &= 0.000255663462. \end{aligned}$$

But the sines of very small angles increasing and decreasing as the angles themselves, that is, as the number of minutes they contain,

$$\therefore \sin 1' : \sin \frac{30^\circ}{2^{11}} = 1' : \frac{30^\circ}{2^{11}} = 1' : \frac{30 \times 60 \times 1'}{2^{11}}$$

$$= 1' : \frac{225}{256} = 1 : 0.000290888204$$

$$\therefore \sin 1' = 0.000290888204.$$

$$\begin{aligned} \text{So also } \cos 1' &= \sqrt{1 - \sin^2 1'} = \sqrt{1 - (0.000290888204)^2} \\ &= 0.9999999577. \end{aligned}$$

If $\sin 30'$ be determined from the formula,

$$\sin A = \frac{1}{2} \{ \sqrt{1 + \sin 2A} - \sqrt{1 - \sin 2A} \}, \text{ we have}$$

$$\sin 30' = \frac{1}{2} \{ \sqrt{1 + \sin 1'} - \sqrt{1 - \sin 1'} \}$$

$= 0.000145199$, which is very nearly equal to half the sine of $1'$, since the angle is small;

$$\begin{aligned} \therefore \cos 30'' &= \sqrt{1 - \cos^2 30'} = \sqrt{1 - (0.000145199)^2} \\ &= 0.9999999896. \end{aligned}$$

Since the sine and cosine of $1'$ and $30''$ are known, the sines and cosines of all angles from $1'$ or $30''$ up to 90° , differing from one another by $1'$ or $30''$, can easily be determined. This is effected by the convenient formulæ of

$$\begin{aligned} \sin nA &= 2 \sin (n-1)A \cdot \cos A - \sin (n-2)A, \text{ and} \\ \cos nA &= 2 \cos (n-1)A \cdot \cos A - \cos (n-2)A, \end{aligned}$$

in which, make $A = 1'$, and for n write successively the natural numbers 2, 3, &c., and

Trigonometrical Canon.

$$\begin{aligned}\sin 2' &= 2 \sin 1' \cdot \cos 1' - \sin 0' = 0.0005817764 \\ \sin 3' &= 2 \sin 2' \cdot \cos 1' - \sin 1' = 0.0008726645 \\ \sin 4' &= 2 \sin 3' \cdot \cos 1' - \sin 2' = 0.0011635526 \\ &\&c. = \&c. = \&c. \\ \cos 2' &= 2 \cos 1' \cdot \cos 1' - \cos 0' = 0.9999998308 \\ \cos 3' &= 2 \cos 2' \cdot \cos 1' - \cos 1' = 0.9999996192 \\ \cos 4' &= 2 \cos 3' \cdot \cos 1' - \cos 2' = 0.9999993231 \\ &\&c. = \&c. = \&c.\end{aligned}$$

Now it would be very inconvenient to register so many cyphers which necessarily enter the values of the sines of small angles; therefore, in order to avoid this, the sines, cosines, and the quantities which are derived from them, are multiplied by 10,000, or a suitable power of 10; that is, the decimal point is removed four or more places to the right, previous to their being registered in the tables. If the *real* values of the sines, cosines, and the other quantities dependent thereon, be tabulated, without being multiplied by any power of 10, the tables are known as *Tables of Natural Sines, Cosines, Tangents, &c.*

In this manner, therefore, we can easily derive from the preceding results the sines and cosines of all angles from 1' to 90°.

The same quantities may also be obtained from the formula $\sin(A+B) + \sin(A-B) = 2 \sin A \cos B$, which may be thrown into the form of

$$\sin(A+B) = \sin A + \{\sin A - \sin(A-B)\} - \sin A \left(2 \sin \frac{B}{2}\right)^2;$$

so that if $B = 1'$, and if for A we write successively 1', 2', 3', &c., we have, *e.g.* when $A = 1'$, and $B = 1'$, $\sin 2' = \sin 1' + (\sin 1' - \sin 0') - \sin 1' \cdot (2 \sin 30'')^2$.

In either case, we shall have a long multiplication to perform, but the same result.

But we need not proceed in these calculations beyond the sine and cosine of 45°, for the same values will recur from 45° to 90°. The reason of this is because $\sin(45^\circ + A)$

$$= \cos(90^\circ - (45^\circ + A)) = \cos(45^\circ - A); \text{ and also}$$

$$\cos(45^\circ + A) = \sin(90^\circ - (45^\circ + A)) = \sin(45^\circ - A).$$

Hence a trigonometrical canon of sines and cosines is completed at 45°.

When, however, the sines and cosines have been computed from 1' up to 30°, the labour and risk of error in finding long products may be much diminished, by determining the value of the sine or cosine by addition and subtraction. Thus, we have

$$2 \sin A \cdot \cos B = \sin(A+B) + \sin(A-B), \text{ and}$$

$$2 \sin A \cdot \sin B = \cos(A-B) - \cos(A+B).$$

$$\text{Let } A = 30^\circ, \text{ then } 2 \sin A = 2 \sin 30^\circ = 1;$$

$$\therefore \cos B = \sin(30^\circ + B) + \sin(30^\circ - B) \text{ (i.), and}$$

$$\sin B = \cos(30^\circ - B) - \cos(30^\circ + B) \text{ (ii.).}$$

In these expressions, let B increase by 1' at a time, from 0° up to 30°, and we shall have all sines and cosines from 30° up to 60°: for

$$\sin 30^\circ 1' = \cos 1' - \sin 29^\circ 59'$$

$$\sin 30^\circ 2' = \cos 2' - \sin 29^\circ 58'$$

$$\&c. = \&c.$$

$$\cos 30^\circ 1' = \cos 29^\circ 59' - \sin 1'$$

$$\cos 30^\circ 2' = \cos 29^\circ 58' - \sin 2'$$

$$\&c. = \&c.$$

Again, in order to derive the sines and cosines of all angles from 60° up to 90°, we have

$$2 \cos A \cdot \sin B = \sin(A+B) - \sin(A-B), \text{ and,}$$

$$2 \cos A \cdot \cos B = \cos(A+B) + \cos(A-B).$$

$$\text{Let } A = 60^\circ, \text{ then } 2 \cos A = 2 \cos 60^\circ = 1;$$

$$\therefore \sin B = \sin(60^\circ + B) - \sin(60^\circ - B), \text{ (iii.), and}$$

$$\cos B = \cos(60^\circ + B) + \cos(60^\circ - B), \text{ (iv.).}$$

Give B all values from 0° up to 30°, the increase being by 1' at a time;

$$\therefore \sin 60^\circ 1' = \sin 1' + \sin 59^\circ 59'$$

$$\sin 60^\circ 2' = \sin 2' + \sin 59^\circ 58',$$

$$\&c. = \&c.$$

$$\cos 60^\circ 1' = \cos 1' - \cos 59^\circ 59'$$

$$\cos 60^\circ 2' = \cos 2' - \cos 59^\circ 58'$$

$$\&c. = \&c.$$

Trigonometrical Canon.

When the sines and cosines of all angles from 0° up to 90° have been computed, they form the basis for calculating the tangents and cotangents, the secants and cosecants, of

all angles from 0° up to 90°. For $\tan A = \frac{\sin A}{\cos A}$; $\cot A =$

$$\frac{\cos A}{\sin A} = \frac{1}{\tan A}; \sec A = \frac{1}{\cos A}; \operatorname{cosec} A = \frac{1}{\sin A}.$$

But if we suppose that the tangents of all angles from 0° up to 45° have been already tabulated, those from 45° up to 90° may be obtained very simply from the formula

$$2 \tan 2A = \tan(45^\circ + A) + \tan(45^\circ - A).$$

Let now A receive increments of 1' at a time;

$$\therefore \tan 45^\circ 1' = 2 \tan 2' + \tan 44^\circ 59'$$

$$\tan 45^\circ 2' = 2 \tan 4' + \tan 44^\circ 58'$$

$$\tan 45^\circ 3' = 2 \tan 6' + \tan 44^\circ 57',$$

$$\&c. = \&c.$$

The tangents of all angles being known, the cotangents are deduced therefrom; and although the sines and cosines will enable us to find the cosecants and secants respectively, yet the same quantities will be found much more simply by the following formulæ:—

$$2 \sec A = \tan\left(45^\circ + \frac{A}{2}\right) + \cot\left(45^\circ + \frac{A}{2}\right) \text{ and}$$

$$2 \operatorname{cosec} A = \tan \frac{A}{2} + \cot \frac{A}{2}.$$

Let A increase by 1' at a time, then, on $\sec A$ and $\operatorname{cosec} A$ becoming $\sec 45^\circ$, and $\operatorname{cosec} 45^\circ$, we shall have the one the complement of the other, since $\sec A = \operatorname{cosec}(90^\circ - A)$;

$$\therefore \sec 1' = \frac{1}{2} (\tan 45^\circ 0' 30'' + \cot 45^\circ 0' 30'')$$

$$\sec 2' = \frac{1}{2} (\tan 45^\circ 1' + \cot 45^\circ 1')$$

$$\sec 3' = \frac{1}{2} (\tan 45^\circ 1' 30'' + \cot 45^\circ 1' 30'')$$

$$\&c. = \&c.$$

$$\operatorname{cosec} 1' = \frac{1}{2} (\tan 30'' + \cot 30'')$$

$$\operatorname{cosec} 2' = \frac{1}{2} (\tan 1' + \cot 1')$$

$$\operatorname{cosec} 3' = \frac{1}{2} (\tan 1' 30'' + \cot 1' 30'')$$

$$\&c. = \&c.$$

We have already seen, that with respect to the sines and cosines, the tabulated results need be carried no further than 45°; the same may be said of the other elements which have been mentioned. For $\tan A = \cot(90^\circ - A)$; $\sec A = \operatorname{cosec}(90^\circ - A)$. Hence, at the top of trigonometrical tables the angles increase forwards from 0° to 45°, while at the bottom they proceed backwards from 45° to 90°.

In the construction of these trigonometrical canons, however, it is absolutely necessary to have formulæ of *verification*, or checks to verify, or rather to examine, the accuracy of the results as they progress from 0° up to 45°; for an error in one result is communicated to each quantity.

These formulæ of verification are, besides I. II. III. IV. :—
 $\cos(36^\circ + A) - \cos(72^\circ - A) + \cos(36^\circ - A) - \cos(72^\circ + A) = \cos A$;
 $\sin A + \sin(36^\circ - A) + \sin(72^\circ + A) = \sin(36^\circ + A) + \sin(72^\circ - A)$;
 $\sin(54^\circ + A) + \sin(54^\circ - A) - \sin(18^\circ + A) - \sin(18^\circ - A) = \cos A$.
 $\&c. \quad \&c.$

Suppose now that the sines, cosines, &c., of all angles have been calculated, radius being unity, and that we multiply each natural sine, cosine, &c., by 10,000,000,000 = 10^{10} , the logarithm of which is 10, then if of each of these new values we take the logarithm, and register such values in tables, we shall have a *logarithmic canon* of sines, cosines, &c.; and, therefore, the logarithms of the sines instead of the sines themselves. These logarithmic sines, &c., are found to be much more convenient in calculation than the natural sines, which are hence omitted in logarithmic tables. The *real* logarithm is found by subtracting 10 from the characteristics of the tabulated logarithms.

CHAPTER I.

The Psychological Data of Logic.

The rela-
tion be-
tween logic
and psy-
chology.

1. Logic is the theory of inference. Round this assertion circulate all endeavours towards precise definition of the science. Its function would thus be very incompletely described, if we were to refuse including, under the name of inference, any processes of thought having data narrower than those of the Syllogism. But we ought to comprehend, within the sphere of inference, all processes wherein a truth, involved in a thought or thoughts given as antecedent, is evolved in a thought which is found as consequent. On this understanding of the term, the Laws of Inference may rightly be said to be those which it is the function of Logic to develop into a system.

Logic, as being thus a systematic development of certain mental laws, takes its place among the sciences constituting the Philosophy of Mind. It is one of those derivative sciences, which branch off on all sides from Psychology, the one original and central science of the cycle.

The data which it has imperatively to demand from psychology are, doubtless, both fewer and nearer to the surface, than those which are required by any other science standing in the same predicament. They are so few, and so intimately related to each other, that in one page of the great psychological volume we read them all: they are so simple and obvious, that psychological controversies raise questions only as to the way of naming them, and leave the facts themselves quite untouched. They might be, and very often are, taken for granted without reference to the science which is their real source; and the borrowing is still further disguised when they are merely, one after another, brought to light as they are needed for use.

But there are more reasons than one for treating them differently.

The chief reason is this. The laws of thought which logic develops are necessary and universal. Therefore we are, especially if we aim at studying the science with scientific precision, in danger of forgetting that its truths, though not measured by experience, become known to us only through experience, that is, in the actual exercise of thought; that those forms of thought, to which all logical laws are relative, are themselves actually conditioned, and conditioned from without as well as from within; and that, if the laws are to have practical applicability as regulative canons of knowledge, their foundation must be firmly laid among the actualities of mental manifestation. The dependence of logic on psychology must be broadly asserted, in the way of protest against systems which seek to divorce it from experience.

Again, the province of logic cannot be clearly distinguished, unless its data have been expressly separated from the uses to which it puts them. It must assume Apprehension and Judgment, as the Forms of those thoughts which are the constitutive factors of inference: it must assume the Laws, both subjective and objective, by which Apprehension and Judgment are universally governed. Its duty is the development of those laws as bearing on those forms.

Lastly, however readily the data of our science might be admitted if presented in a loose and unscientific shape, it is by psychology that they have been systematized, justified, and designated. They are not available for precise and exhaustive use, unless they are laid down and named with

the utmost exactness which psychological analysis has made it possible to attain.

Introduc-
tion.

2. It may be desirable to begin our hasty psychological survey, by explicitly setting aside those classes of mental phenomena whose laws are not logical.

When the phenomena of consciousness are considered subjectively, or purely as functions of the conscious mind, they seem to be naturally distributable into four Primary Modes. With three of these logic is in no way concerned. It does not deal with Feeling (or cognition without distinct evolution of the objects), in either of its objective varieties of sensation and emotion; nor with Wishing or Appetency, either as desire or as aversion; nor with Volition, the consequent of wishing, as that is of cognition. Its sphere lies wholly within the fourth of the modes; that is, among the facts which are describable as Thinking or Cognition, pure and proper: in other words, it lies among the phenomena which only are strictly describable, in the current phrase, as operations of Intellect or Understanding.

Nor is it as to all of these that logic requires to assume anything. It ignores, especially, one of the two great divisions into which, through differences in the character of cognizable objects, all human thought or knowledge is distributable. We know or think of an object, either directly, or through another object which represents it. Knowledge of the former kind has been called Immediate, Intuitive, or Presentative; that of the latter kind, Mediate or Representative. All objects that are cognizable immediately, may also be known mediately or representatively; but by far the most valuable part of our knowledge has objects which are cognizable mediately and not otherwise.

It is only with facts of mediate knowledge that logic can deal. It is when, and only when, reproduced from the past in present facts of thought, that immediate cognitions or their objects are susceptible of analysis or evolution. Consequently, these yield materials open to logical scrutiny, when, but only when, they are so reproduced; while, further, there is exposed to such scrutiny the whole gigantic mass of those complex cognitions, whose prominent elements are objects mediately known, and in which immediate cognition supplies only, as it always must, elements which are implicitly and obscurely assumed.

3. From the field of logic there are thus shut out all those mental facts, which are not contained in the sphere of mediate thinking. Within that sphere, the field of the science receives still another limitation. The only matter with which it deals is that which the schoolmen called Discourse or Discursive Thought.

The name hints at the character of the thing. Discursive thinking is a passing from thought to thought. Logic evolves, not laws which govern any one fact of mediate thinking taken singly, but relations between two or more such facts, or laws which govern the derivation of one such fact from another or others. That which logic scrutinizes is not one fact of thought, but a process constituted by a plurality of such facts. It considers Thinking as Knowledge or Cognition, that is, as having objects which are truths; but it assumes and systematizes those laws only in virtue of which, one or more facts of knowledge being given, other facts of knowledge may be elicited from them. The logical question is not, whether a given judgment or assertion is true or false. It is only whether, in virtue of certain

The modes
of con-
sciousness
not cog-
nizable by
logic.

Discursive
thought the
matter of
logic.

Introduc-
tion.

laws of thought, there does or does not subsist, between two or more judgments or assertions, the correlation of antecedent and consequent; whether, one or more of the assertions being admitted, another must be admitted, or must be denied, or may be either denied or admitted. In short, the processes whose laws the science digests, possess always the essential characteristics of inference; and they are always, also, reducible into a form to which that name is directly and properly applicable.

Psychologically or subjectively considered, discursive thought exhibits no distinctive characteristics beyond those which belong to it as being necessarily mediate or representative. It is always resolvable into a series of judgments. Its peculiarity lies in the relation between the constitutive judgments: it is a relation in which the objective side is the more prominent of the two. We might say, indeed, that the relation subsists, not between the acts of judging, but between the judgments; not between one mental fact and another, but between their several results or products. The ideas which are the factors of each judgment must represent objects which, if not real, are at least thinkable: each judgment is given to logic in that aspect. It is only after having been so viewed, that the judgment is, as it were, turned round, to be examined from the opposite, the subjective side. A certain relation between thinkable objects being assumed in the antecedent judgment or judgments, the Laws of Thought compel us to think another relation between thinkable objects in the judgment which is the consequent.¹

Mediate
thinking
formally
distinguishable
as apprehension or
judgment.

4. All the laws of discursive thought bear on certain Forms, in which, and in which only, the facts of mediate thinking which constitute the process are possible.

Mediate thinking must always take the one or the other of two forms; forms whose difference is as truly subjective or formal as those which mark the four primary modes of consciousness. It must be either a fact of Apprehension or a fact of Judgment; species recognised most readily through the test of expression as brought to light by logical analysis. Every fact of thought expressible by a Term (that is, by a word or words interpretable as the name of an object or objects), is formally a fact of apprehension. Every fact of thought expressible by a Proposition or Asser-

¹ In the nomenclature of the German schools, the name Thinking or Thought is confined (at widest) to Thought Discursive. The same limitation has of late come into use among us. It is adopted by Sir William Hamilton, who acknowledges only this meaning of the word, and that other in which it covers all kinds of mental phenomena. "Thought and Thinking are used in a more and in a less restricted signification. In the former meaning, they are limited to the discursive energies alone; in the latter, they are co-extensive with consciousness." (*Edition of Reid*, p. 222). In this view, perception, whether external or internal, is not thinking in the narrow sense of the term; neither is imagination, whether it be simply reproductive, on the one hand, or creative or synthetic on the other.

In the text, the word Thinking is used as synonymous with Intellect or Intelligence. In the psychological scheme which was hinted at in the last section, Thinking, Intelligence, Cognition, is regarded as distributable into modes or kinds on each of two principles. Considered subjectively or formally, it must take place in the one or the other of the two forms which are called Apprehension and Judgment. Considered objectively, that is, as modified by the character of the objects known or thought of, thinking falls, first, into the two genera of Immediate and Mediate. Immediate thinking is of two species, Self-Consciousness and Consciousness Perceptive (perception, internal and external); facts of both kinds being indeed actually complex, and especially having Feeling as an element, but both being susceptible of being regarded abstractively as facts of pure and proper thinking or cognition. Mediate thinking embraces two species; first, Imagination proper, that is, the thinking of individual objects not present (which, again, may be either simply reproductive or synthetic); and, secondly, Conception proper, or the thinking of universals. Both Imagination and Conception take spontaneously the form of Apprehension; but both, besides presupposing Judgments, yield matter for new Judgments, which are necessarily Mediate.

tion or Predication, is formally a fact of judgment. Every thinkable object, or group of objects, no matter how complex our thought of it may be, is denotable by a term, if only we have words adequate to express all the elements which we think of it as involving. Every act of thought in which we explicate a relation, is denotable by a proposition, and requires the propositional form.

Introduc-
tion.

5. (1.) The first formal determination of Judgment is The formal one which, as we shall find, lies at the very root of all logic-character-ical doctrine. A judgment, or the proposition which expresses it, must always be either Affirmative or Negative: a judgment which should be neither the one nor the other is utterly inconceivable: there is no medium between affirmation and negation.

(2.) Every judgment, further, is formally resolvable into the affirmation or denial of a Relation; and relation implies plurality of ideas or objects related. We shall immediately, it is true, encounter a class of cases in which there is not really such a plurality; and the possibility of these will at once prescribe a limit to logical analysis, and serve as a point of departure for the development of judgments really founded on relation. In the mean time, it must be noted that the formally relative character of all judgments, impressing itself necessarily on the propositions by which all judgments must be expressed, makes it possible, while for exact logical scrutiny it is necessary, to dissect all propositions into three factors or constitutive elements. They are these: the two Terms (Subject and Predicate), which are names of the ideas or objects correlated; and the Copula, in which the relation is asserted. The subject denotes that which is the datum or antecedent of the judgment, that which is given to be determined by the other term. The predicate denotes that which is the quæsitum or consequent, that by which the subject is determined. The copula asserts the relation, but it asserts nothing more; and, that we may make the closest possible approach to a pure affirmation or denial, it must always, for strict logical use, be either "is" or "is not," "are" or "are not." It might be said, that the terms are the objective factors of a proposition, and that the copula is its subjective factor.

(3.) There emerges thus, as necessary to be assumed in all further steps, the doctrine of that which logicians call the *Quality* of propositions. Judgments and propositions must be either *Affirmative* or *Negative*; and the quality of a given proposition is signified by its copula.

6. The formal theory of judgment, in itself exceedingly simple, becomes perplexingly complicated through the complexity inseparable from the theory of apprehension.

Apprehension, as the name is here understood, is the Simple Apprehension of the logicians; that is, mere apprehension not evolved into judgment. We give the fact that name, when we desire to describe it by reference to the thinking subject, or as a mental act or phenomenon: when we desire to describe it as representative of an object or objects, it may be, and is, called an Idea or Notion. The idea or notion is that which is directly denoted in language by a Term; and a term is thus, mediately, the name of an object or objects. The names apprehension and idea denote one and the same fact; but they denote it as regarded from two opposite points of view, from either of which it may be contemplated, but not from both at once.

The differences between objects apprehensible, must modify variously the character of the ideas and terms through which they are thought. But, of all such differences, there is only one which modifies the form of apprehension necessarily and always, and which, therefore, possesses a peremptory logical value. It is the difference between the Individual and the Universal. This difference yields two varieties of apprehension; namely, Imagination and Conception. We

The formal
character-
istics of
apprehen-
sion.

Introduc-
tion.

apprehend the individual in imagination, which, objectively viewed, gives an Image: we apprehend the universal in conception, which, objectively viewed, gives a Concept. The image is expressed in words by a Singular Term; the concept by a Common or Generic Term.

The Singular Term is a name for an object thought as having unity, or as being one object. Its unity or individuality may be constituted by parts, each of which might in its turn be thought as one; but it is thought under some relation yielding a unity, which cannot be thought away until some other relation is substituted for the first. "Aristotle," "John Milton," "This man," are not more distinctly singular terms, than are these: "The course of conduct to be adopted," "The (individual) series of fancies which lately floated through my mind." "Yonder forest" is a singular term; so are "That tree of yonder forest," "The gnarled bough of that tree."

The Common Term is the Name of a Class, a name for a plurality of objects, a name applicable to any or all of them in respect of a certain relation between them. Its meaning as a name of objects is not exhausted unless it is applied to all; as "All poets," "All the trees in the wood:" but, continuing to think of the objects under the same relation, we may apply it to some, or to any number of objects fewer than all, as "Some poets," "Most of the trees in the wood."

One feature of contrast should here be noted, as having a wide logical applicability. Apprehension may be either Direct or Symbolic. Imagination is a direct apprehension: if we think of an individual object through a name, we think symbolically; but it is not necessary we should so think of such an object. A person remembered is thought of directly when we call up his image, the representation of his appearance. Contrariwise (and this is the point to be noted), conception is necessarily symbolic. That which is signified by a common term, cannot be represented in thought otherwise than through a symbol; and words, if not the only possible symbols, are the only ones that are fully adequate for the purpose. Why the case should so stand, is a question very abstruse, and not logical. But some of the reasons may come to light when we have examined the common term a little more closely, and have discovered that it represents, not anything actually known before, but a complex thought which has resulted from a comparison of known objects. In the meantime it should be remembered that, in a certain view, "concept" and "common term" mean one and the same thing; that, at the very least, the thought which we call a concept is not only not expressible, but not even thinkable, unless through the common term.

The exten-
sion and
compre-
hension of
common
terms.

7. The signification of the common term is double. It is a name both of substance and of attribute: it is a name both of objects possessing an attribute, and of an attribute possessed by objects.

Most obviously it is, as it was already described, the name of a class, of a plurality of objects. But it is a name of these as thought under a relation; and that relation is, their possession of a common attribute. It is, indeed, applicable to all and each of the objects, just because, and in so far as, they are thought as possessing a certain attribute, or a combination of attributes, which combination is usually thinkable as one attribute more or less complex.

If we attempt to trace hypothetically the formation of a common term, we shall find that the discovery of the attribute must have preceded the imposition of the name.

One of the conditions under which only we can think of objects, is that of Number, which develops itself in the phases of unity, plurality, and totality. If our given objects are more than one, our contemplation of them is obscure and unsatisfactory: we constantly strive in thought to attain unity. But, an individual and simple unity being here unattainable, we endeavour at least to gain a com-

Introduc-
tion.

plex unity, that is, a totality constituted by parts. We endeavour to think of our plurality of objects in a relation in which they are such constitutive parts. But such a relation must be that of resemblance: it must lie in the fact, ascertained by us, or for us, through observation, that each of the objects possesses a certain attribute or property. The common term, borrowed or invented, will then enable us to think of our objects as being "all," but only as being "all" in respect of their possession of the common attribute.

Now, this two-fold relation of the common term is the most fruitful of all logical data. Therefore we had better seize, at once, names by which both of its members may be technically described. The objective relation of the term, its signification as being a name of objects, will be called its *Extension*: its attributive relation, its signification as a name of attribute, will be called its *Comprehension*. The common term "man" has extension, as being a name for all and each of the persons constituting the class; it has comprehension, as being a name for the attribute "human nature."

The Extension of the common term is, naturally and necessarily, the more prominent relation of the two, in thought as well as in expression. It costs an effort to think, and it requires an abstract form to express, the common term as the name of an attribute. The common term, as the name of a class of objects, is readily thought, and finds its expression in a concrete form. Again, the relation of number, or of whole and part (involving quantity in one phase or another), is an element of every thought in which a concept is one of the factors. The question must always be raised, whether the objects thought of are all, or only some, of the objects constituting the class: the question is, in other words, whether a given term is, in a case under examination, used in the whole, or only in a part, of its extension.

There emerges thus the doctrine of that which logicians call *Quantity*. Every common term must be considered with reference to its quantity. It must either be *Distributed*, that is, applied to all the objects of the class; or it must be *Undistributed*, that is, applied to fewer than all of the objects. Distribution and non-distribution are indicated by prefixed Quantitative Signs: "all" or "any" for the former, "some" for the latter. A proposition, again, is specially said to be *Universal* when its subject is distributed, that is, when the antecedent of the judgment is the whole of a class; it is said to be *Particular* when the subject is undistributed.

8. Logic does not require to assume that common terms have undergone any deeper probing, than that which detects in them the formal expression of the correlation between substance and attribute, and of that reference of objects to classes for the sake of which the correlation is thought of. But both their character, and the limits which circumscribe logical dealing with them, may be more clearly understood, through a cursory glance at those objective conditions by which their formation is determined.

Classification, as a process yielding concepts and terms which import real knowledge, is very far from being arbitrary. When we endeavour to refer objects to a class, in virtue of a common attribute, that which is sought is, in effect, some one law under which we may know or believe that all the objects are placed. But every thinkable object is, in virtue of the complications involved in life and nature, amenable to many laws, and may therefore be thought of as possessing each of many attributes. Each individual object may be placed in any of many classes, or have affirmed of it any of many common terms, denoting attributes common to it and to other objects, that is, laws which both they and it obey. So, likewise, of any class of objects (if we set aside the unpractical case of a class wide enough to

Introduc-
tion.

contain all others), it must be affirmable that it is included in some other class; while of most classes it must be affirmable that they are, when considered with reference to diverse attributes or laws, included in each of many others. Thus common terms are affirmable of each other; and it is out of such affirmation, with the negations accompanying it, that there comes the only matter of reasoning difficult enough to reward scientific scrutiny, or complex enough to bring into play the highest logical doctrines.

Again, the classes which are thus comparable can very seldom be co-extensive: those which we do compare in ordinary facts of thinking never are so. Common terms, accordingly, distribute themselves into systems, each of which constitutes a graduated series. A class containing certain objects is placed in a class containing these objects, together with others. This second class is similarly placed in another, containing all its objects, but not these alone; and the series may so rise in many successive steps. Thus we may pass from "man" to "animal," from "animal" to "creature organized," and thence, if we will, to "created being." When terms are taken in such an order, their extension increases at every step; each succeeding class is thought of as containing more objects than the class which last preceded it. A very little reflection will show that, contrariwise, the comprehension of the terms has decreased at every step. Each succeeding term implies an attribute (simple or complex) fewer than that by which it was last preceded. "Animal," being the name of a class containing objects besides "man," ceases to suggest the attributes which distinguish man from those other objects; and "organized creature," as being the name of a class containing both "animals" and "plants," ceases to suggest the attributes which distinguish "animals" on the one side, and "plants" on the other. In short, when we think according to this order, we are, step by step, thinking *in* objects, and thinking *out* attributes. This is the course of thought which is usually called Generalization.

The counterpart of it is the process of Specification or Determination. In it we begin with the most extensive class, and descend, step by step, till we reach the lowest. In so doing, we are, quite as evidently, thinking *out* objects and thinking *in* attributes. Each successive class in the descent contains fewer objects than the last; but each possesses, in addition to the attribute of the preceding class, the attribute possessed by its objects, and wanting to the objects which with it make up the class preceding.

Thus there comes to the surface one of the most valuable of all the laws from which logic draws corollaries bearing on inference. It is the *Law of the Inverse Ratio* which subsists between the Extension of common terms and their Comprehension.

Corollaries
as to com-
mon terms.

9. There may be noted, further, in the way of corollaries, one or two features of the common term, which are important as bearing on its logical uses.

(1.) The concept tends to fall back into the image. It is usually held that all class-names must originally have been the names of individuals; nor is it easy to suppose any other source for them. At all events, when we consider the existing state of language, without speculating as to its formation, it becomes evident that the common term, as being a name applicable to every object of the class, has a suggestive force, leading us downwards towards agination of objects individual. In this aspect, the term may be regarded as giving an inadequate idea, an obscure and vague image, of the individual,—an image that becomes more and more indistinct, the wider the generalization is which the term presupposes. Concepts, therefore, though properly representing, not objects, but the manner in which we think of them, cannot entirely lose their hold of objects: and reality, actual existence, operates as a normal limit to the formation of concepts and common terms.

Introduc-
tion.

(2.) The concept, however, *qua* concept, is not used for the purpose of suggesting any reference to individuality. It is a thought of relation, and therefore a complex thought; its elements are discoverable, and may be brought to light in the form of a judgment. The signification of a common term is most clearly and fully perceived, when it is regarded as being an abbreviated symbol of a complex proposition, the import of which might be formulized in some such shape as this: "All the objects thought of are objects possessing a certain attribute, and therefore constituting a certain class."

Indeed, this manner of considering terms, as being shorthand expressions for propositions previously gained, is capable of being put to very various uses. All logical rules which are easily available, and all primary logical principles, are brought to bear by the separate extrication, from propositions, of the terms which are their objective factors. If we attempt logically to compare propositions without such dissection, they can be treated only through the cumbrous and derivative rules of hypotheticals, or other complex forms of predication. Categorical predication, the normal and simple expression of judgment, yields the terms immediately and easily. But such predication is often not attainable till propositions have been condensed into the form of terms; and it is, perhaps, traceable always to such a condensation, which we perform spontaneously and continually, guided by the irresistible desire of making language keep pace, as far as its natural slowness will allow, with the electric rapidity of unexpressed thought. This condensation comes into action with especial frequency in our thinking of universals; since these are never thought unless through words.

CHAPTER II.

The Function and Axioms of Logical Science.

10. Knowledge requires both to be gained and to be verified. It is desirable that we should obtain aid, through systematic laws, both for discovering new truths and for testing the results of alleged discovery. A Theory of Derivative Knowledge would be complete, if it issued a twofold code, ruling, with scientific accuracy, processes of both kinds. The two-
fold code of
discursive
thought.

A system aiming at the former of these ends is properly constructive or positive: if it is capable of justifying its promise, operations directed by it will yield positive additions to our knowledge. A system aiming at the other end is no more than regulative or negative: it can only enable us to decide, whether that which is presented as knowledge deserves or does not deserve the name.

It is confessed by all that the Code of Discovery has never yet been thoroughly digested; it is believed generally, and perhaps universally, that it must always at many points remain imperfect. In all the shapes in which it has been promulgated, it is described commonly, though neither quite correctly nor quite completely, as the Philosophy of Induction. Some of those who have legislated for this region of logical science maintain it to be practically independent of the other; not that they hold the testing of results to be unimportant, but that they believe this duty to need no scientific assistance, and to be safely left to native sense and practised sagacity. By such thinkers, the laws of discovery are asserted to constitute the only logical system that is worthy of study. Others allow, more correctly, that a developed theory of the processes by which thought may be tested, is imperatively necessary as the foundation for a theory of discovery. These speculators usually consider the systematized theory of induction or discovery as constituting, in one department or in several, an Applied or Particular Logic; in respect that it is a scheme in which logical laws, the laws for the testing of thought, are applied to special uses, varied by the varying character of the purpose and the matter.

Introduc-
tion.

The Testing of Discursive Thought is the function undertaken by that system of logical science, which has been called the Aristotelian, from its founder or greatest expositor; the Syllogistic, from the process which is its highest development. It has been spoken of as a Pure Logic, because it is, or may be made, as far free from assumptions foreign to it, as any science can be which has human thought for its matter, and by which, therefore, certain laws of the human mind must be taken for granted, on the faith either of ordinary experience or of psychological analysis. It has been called Universal Logic, because its laws are applicable indifferently to all processes of discursive thinking, whatever may be the kind of the matter or objects thought of. Often, also, for the last of these reasons, it is called Formal Logic: its laws are laws, not of the matter of thought, but of the form or manner in which the matter is thought of. It professes to assign laws through which, on the assumption that the data of derivative knowledge are true, it may always be determined, either that the results are true, or that their truth or falsehood is not fixed by the data. This profession the science makes good, with a comprehensive precision which has, paradoxically enough, been turned into a ground of objection to it.

First deter-
mination of
the func-
tion of
logic; the
regulation
of explica-
tive
thought.

11. That which will here be attempted is an exposition of the laws constituting the science of Pure or Universal Logic. These, indeed, are the only laws which can correctly be called logical. The theory of discovery is logical so far only as it rests on those laws, as it must do by implication even when it does not expressly assume them; and it is only through them that the process of discovery can be philosophically theorized, with reference either to its capabilities or to its shortcomings.

It is difficult, perhaps impossible, to reach a formal definition of Logic, which shall at once mark out precisely the limits of the science, and describe its function clearly and exactly.¹ All the purposes of such a definition will be attained, if we can apprehend correctly these three points: first, the character of the mental process which the science examines; secondly, the character of the law which regulates the process, and the development of which is the duty undertaken by the science; thirdly, the character of those objective conditions under which only the process is possible, and with reference to which, therefore, the law must be expounded.

¹ In the following definitions and illustrations, that which is signified by the name "Thought" is discursive thought. "Logic is the *a priori* science of the necessary laws of thought, with reference, not to particular objects, but to all objects whatever." (Kant, *Logik; Einleitung*). "Logic is the science of the rules of thought." . . . "It takes no account of differences among the objects. It contains, therefore, rules for thought as thought; and these rules must consequently be universal and necessary, that is, they must be laws." (Kiesewetter, *Logik*, i., pp. (5) 7, ed. 1824). "Pure logic is the science of the form of thought." (Hoffbauer, *Logik*, p. 27, ed. 1810). "Logic is the science of the laws of thought as thought—that is, of the necessary conditions to which thought, considered in itself, is subject. This is technically called its *Form*. Logic, therefore, supposes an abstraction from all consideration of the *matter* of thought—that is, the infinitude of determinate objects in relation to one or other of which it is actually manifested." (Sir W. Hamilton, *Edition of Reid*, p. 698). "Logic is a formal science: it takes no consideration of real existence or of its relations, but is occupied solely about that existence and those relations which arise through, and are regulated by, the conditions of thought itself." . . . "Logic is discriminated from psychology, metaphysics, &c., as a rational, not a real—as a formal, not a material—science." . . . "It has, in propriety of speech, nothing to do with the process or operation, but is conversant only with its laws." (Hamilton, *Discussions*, pp. 144, 136, 134). "Analytical logic is the science of the formal laws of inference." (Karslake, *Aids to the Study of Logic*, part i., p. 11). "Logic is the science of the laws and products of pure or formal thinking." (Mansel, *Prolegomena Logica*, p. 245).

Introduc-
tion.

(1.) Logic is the Regulative Theory of Explicative Thought. If it were necessary to lay down an express definition of the science, this assertion might be offered as being such: all closer examination yields only explanations of it. But not a little explanation is required.

Thinking may be either Explicative or Analytic on the one hand, Ampliative or Synthetic on the other.¹ For processes of either kind, there must be given one thought at least—a datum or Antecedent. We explicate that thought when we extricate or evolve from it another thought, a thought describable as a Consequent of the first. Inference, reasoning, discursive thought, is merely explication of thought through analysis. If, at any step in the progress of our thinking, we assume any thought not involved in those which had previously been given or evolved, we amplify our thought, we augment the matter of our thinking by the addition of a new datum or antecedent. If this new datum is synthesized or combined with our old ones, or with the thoughts which have been explicated from them, we may institute a new process of explication, in which we infer from our amplified aggregate of data.

It is for pure explication only that logic is competent to legislate. A process to which logical canons are applicable, must be one in which there takes place nothing beyond this; that the constitutive elements of a given thought or thoughts are detected through analysis, and that there is evolved some thought which was involved or implied in the thought or thoughts given. The consequent differs from the antecedent in this only; that the former explicates, brings to light, enables us to think distinctly, something which in the latter was only implied, and, therefore, thought more or less obscurely. Derivative thought, like water flowing through conduit-pipes, cannot rise above the level of its fountain. The truth or falsehood of the thought or thoughts assumed as the starting-point, must be determined by objective considerations, not by the laws of thought. In the same predicament is any uninvolved thought that may be interpolated in the course of the evolution; and, indeed, the introduction of any such thought just makes the beginning of a new process of evolution.

12. (2.) Explicative thought is regulated exclusively by Second law, the Law of Consistency.

The character of this law determines, in several successive steps, the character of the process of explication.

In the first place, it determines the character of the antecedent. If there could be any such thing as a simple thought—a thought which is not analysable into constitutive thoughts, or in which no other thought is implied—such a thought would not be explicable or subject to the law of consistency; and if, in any individual case, we cannot discover what thoughts a given thought implies, that thought is for us inexplicable. Accordingly, a thought given for explication must be assumed to be complex.

Further, the complex thought, given for explication, must be resolvable into the thought of a relation. What this relation is, we cannot think clearly, unless in the form of a judgment, expressible by a proposition. When we ask whether ideas or terms are consistent or inconsistent with each other, the question really is, in what manner the relation presupposed between the ideas qualifies them for being combined as terms of a judgment. Further still, the testing of consistency or inconsistency cannot be exhaustive, until the judgment has been analysed into the elements which in the proposition are signified by the subject, the predicate, and the copula.

Logical rules being most conveniently enounced with reference, not to the judgments and compared ideas, but to the propositions and terms through which these are expressed,

¹ Analytic and synthetic (Kant); Explicative and ampliative (Hamilton).

Introduc-
tion. the law is technically named with the same reference. It is thus called *The Law of Non-contradiction*.

This law, then, might be thus set forth, with reference both to the thought and to its expression, and in the negative aspect which is fittest for laws having uses regulative or prohibitory. "Ideas must not be combined in a judgment, in a form inconsistent with the relation presupposed between them or the objects they represent. Terms must not be combined in a proposition, in a form contradictory of their presupposed signification."

Third de-
termina-
tion of the
function of
logic; the
develop-
ment of the
principle
under uni-
versal ob-
jective
conditions.

13. (3.) This law, self-evident to the extreme of triviality, is not available for use until it has been specified in more degrees than one, through consideration of the Character of those Objects which are Thinkable.

Thinking is possible only when there is given to it matter to be thought of: there must be not only a thinking subject, but a thinkable object. Thinking, accordingly, is conditioned, limited, determined, in each of its two opposite relations. It is conditioned not only subjectively, that is, by the laws which regulate thinking as a function of the thinking mind, but also objectively, that is, by the character of the objects of which it is possible for man to think.

Logic is enabled to elicit formal laws which are universally applicable, not by achieving the impossibility of ignoring the objects of thought, but by considering, of the differences in the kinds of objects, those only which necessarily modify the form of thought or the manner of thinking. Now the number of those differences is the smallest that admits difference at all. We think of objects either, first, as having existence actual or possible; or, secondly, as having also mutual relation. The former of these objective conditions yields the idea of Individuality, the latter that of Universality. Under the one idea or the other all thinkable objects are thought. Individuality, as being the form of existence, lays the foundation of knowledge through intuition; universality, as being the form of relation, makes representative thought available as the instrument of knowledge explicative or discursive.¹

All propo-
sitions re-
solvable
into asser-
tions of
identity or
difference.

14. The law of non-contradiction receives its simplest application in Judgments whose Objects are Individual. This application likewise yields the normal form of the law, the form from which all other forms of it are derived, and into which all of them are in the last analysis reducible. That, in this its simplest shape, the law is (as we shall see) not so expressible as to avoid the double censure of triviality and barrenness, is a fact which would prove only, if proof were needed, that thinking which attempts to compare objects merely as individuals, without regard to their attributes or laws, not only requires no express rules, but is wasted on matter which can yield no real development of knowledge. It is nevertheless true, and demonstrable, that the most complex reasonings in which classes of objects are compared, owe their validity to that one self-evident principle, and that all logical canons are merely corollaries from it.

It is indeed impossible to think, even of individuals, unless under the condition of relation. Individuality implies the relation of number. Therefore, at the very outset, there comes up an indirect refutation of the possibility of constructing a system of logic, which shall be purely a theory of thought, and shall presuppose nothing whatever in regard to the objects thought of.

If, then, a thought having an individual object or objects is to be explicated into the form of judgment, there stands, as a barrier at the entrance of the field, that subjective law of thought which determines all judgments as being either *affirmative* or *negative*. We must either affirm or deny: no other form of judgment is possible.

Whether, again, we are to affirm or to deny, is a question determined by this law, which governs thought in its relation to all thinkable objects. "All objects are primarily thought of under the one or the other of the counter-relations of *Identity* and *Difference*." Of objects individual, when we attempt to consider them purely in their individual aspect, this is a palpable truism. Any one given object is identical with nothing but itself; it is non-identical with every other object. If, then, one object only is given, and if an affirmative assertion is demanded, the only such assertion which the case allows is the tautological and trivial affirmation,—“The object is itself: A is A;” which is an application of the equally barren formula,—“Every thing is that which it is.” If, again, with the same datum, a negative assertion is required, we can frame only this negation,—“The object is not any thing which is not itself: A is not any thing which is not A (= A is not Not-A);” or, in the formulized shape, “A thing is not that which it is not.”

It is needless to say that, plainly, any other assertions than the two set down, would be contradictory of the assumption of the individuality of A.

But it must be asserted, broadly and peremptorily, that all the laws of inference are resolvable into this doctrine:—“An affirmation is an assertion of identity; a negation is an assertion of non-identity; and no medium is thinkable between the one assertion and the other.” In laying down this proposition, we allege the Law of Non-contradiction, and couch it in a shape pointing straight to its place as the central law of logical science

15. The law of non-contradiction is one and indivisible. The three But it may be regarded from any of more points of view logical axioms than one; and one of these will suggest itself rather than yielded by the prin-
the others, when the law comes to be applied on any spe- ciple. The
cial occasion. Accordingly it develops itself in one or laws of
another of three specific forms, which admit of being stated identity,
as three separate canons. These may be described as being difference,
The Three Logical Axioms. and deter-
mination.

Each of these, it must carefully be noted, is merely a partial evolution of the one central law; each of them implies the other two, and would lose not only its force, but even its meaning, if either of the others were wanting. It thus becomes extremely difficult to keep them separate in expression; and, besides this, it is often a matter of choice, to be fixed by the particular aspect in which we contemplate a given process of thought, which of the three is to be held as the rule directly bearing on it. For all these reasons it may be doubted, whether the older practice of leaving the law unevolved, was better or worse than that attempt at distinct evolution of it, which has been adopted by the ablest of the modern logicians, and is here followed in deference to their opinion.

The logical axioms may be introduced in some such shape as the following:—

First, Affirmative judgments are ruled by the Law of Identity. “An affirmative proposition is not secured against inconsistency, unless its predicate may be thought as identical with the subject.” The primary formula of affirmation is this:—“A is A.”

Secondly, Negative judgments are ruled by the Law of Difference or Non-identity. “A negative proposition is not secured against inconsistency, unless its predicate may be thought as non-identical with the subject.” The primary formula of negation is this:—“A is not Not-A.”

Thirdly, Any two ideas must be either affirmable or deniable of each other. “Of any term as subject, any other term must be either affirmable or deniable as predicate.” This axiom is usually called the Law of Excluded Middle, a name intimating the impossibility of any assertion intermediate between the two. It has also been called the Law of Determinability or Determination. The formula is this:—

¹ See Note at the end of the Chapter.

Introduc-
tion.

"Every thing is either A or Not-A: every thing is either a given thing, or something which is not that given thing."¹

Even when viewed from this distant and somewhat hazy station, the axioms yield, more easily than it can be gained otherwise, one distinction which we shall find to be very widely useful. Two Terms, differing in this only, that the one wants, while the other has, the prefixed symbol of negation, are said to be Terms Contradictory. Thus, A and Not-A are contradictory terms. Two terms so related cannot be either affirmed or denied of the same object or group of objects. Of whatever object or objects A may be accepted as a name, Not-A must be understood as a name that covers every thinkable object besides. Such terms are the only terms which are formally and necessarily exclusive or contradictory of each other. If any two terms not formally so distinguished are held to be contradictories, it is because their relation is thought as being equivalent to that of formal contradiction.²

¹ The only point seeming to require comment is the position of the Third Axiom, which some logicians have mistaken so far as to attempt deducing it from the other two. It lies, in fact, subjectively deeper than either of them: a proposition disobeying either of them would be inconsistent with its data, but yet possible; a proposition disobeying the third axiom is inconceivable. The determination towards either affirmation or negation is a law of judgment, discoverable before all scrutiny of objective relations. Yet the third axiom, in the shape in which it has just been couched (or in any other making it available for use), is not independent of the other two. Though we know before-hand that, if we are to assert at all, we must either affirm or deny, we yet do not, surely, know what terms must be affirmable or deniable of what others, till we have, through the first and second axioms, resolved affirmation and negation into assertions of identity and difference. This resolution being made, we are reminded that any two terms must denote either one and the same object, or two objects which are different. If the former is the case, there is ground for affirmation; if the latter, there is ground for negation: and thus only does it appear that predication of the one kind or the other is possible with any two terms.

² The formal evolution of the Law of Non-contradiction into the Three Axioms has been a gradual process, brought to its consummation by the German logicians since the time of Kant. The laws of identity and difference have often been treated and expressed as one, oftenest called the Law of Contradiction; and, perhaps, the doctrine is most clearly apprehended when taken in this way.

The older logicians, as well as some of the more recent, seem to have frequently lost their way to the strict application of the law, through want of distinct thinking of the Quantitative Sign as an integral part of the term; an indistinctness which issued in the explaining away of numerical identity and difference into identities and differences specific and generic. The law of excluded middle, constantly and inevitably assumed and acted on, was kept in the background through the very facts of its palpability and its originally subjective obligation. Its formal introduction into logic as a separate axiom appears to be modern. Bachmann has collected a good many points in the recent history of the three axioms. (*System der Logik*, part i., sect. 2).

By Kant himself, and by several other German writers, there is added to the law of non-contradiction, as being also a logical law, Leibnitz's principle of the Sufficient Reason. There is unquestionable soundness in the objection taken to this addition by Sir William Hamilton, and by more than one of the Germans. If the doctrine means that nothing can exist without a sufficient reason, it is an assertion of the metaphysical law of causality; if it means that nothing can be believed or known without a sufficient reason, it is an assertion developed purely out of the laws of identity and difference.

The law of non-contradiction was neither generalized, nor formally planted at the root of the science, by any of the Greek logicians. (See Prantl, *Geschichte der Logik im Abendlande*, vol. i., 1855). Prantl, however, cites references by Plato to the law of identity (the bearing of which he questions): and he has made, from Aristotle, a large collection of passages which yield unequivocal assertions of all the three axioms; while, also, the law of identity is explicitly declared by Aristotle to be the firmest principle of thought. The following, selected from Aristotle by Trendelenburg for his *Elementa Logices Aristotelicae* (ed. 1852, §§ 9, 10,) are probably more marked than any other of Prantl's quotations.—"Τὸ αὐτὸ ἄμειν ὑπάρχειν τε καὶ μὴ ὑπάρχειν ἀδύνατον τῷ αὐτῷ καὶ κατὰ τὸ αὐτό.

Introduc-
tion.

16. The axioms, as universal laws of thought, must cover all possible cases. The case, also, which has been considered, deserved special notice; because the supposition of one object, as the only thing given to be positively thought of, brings out, with a clearness not otherwise attainable, the primary idea of negation, as an explication of non-identity. That, in attempting affirmation with such data, we are driven on an assertion which is no real explication at all, is a fact not only to be accounted for easily, but leading us rapidly towards the development of the axioms in those cases for which the question of their use is important.

The datum of a proposition is, a relation between that which is denoted by the subject and that which is denoted by the predicate. But when we were required to think of A only, no predicate was given. For negation we found a predicate, by seizing on the supposition, implied in the oneness of the subject, that there must be other thinkable objects besides that, whatever it may be, which our subject signifies. But, the subject being, by the hypothesis, not only one, but something as to which we know positively nothing except its unity, a datum for real affirmation was wanting.

What would have sufficed to supply the want? Another Name, say B, for the thing denoted by the subject: out of this would have come the affirmation, "A is B."

Now, the interpretation to which a proposition thus generated is open, is one which may be put on all propositions whatever. Every affirmative proposition is equivalent to an assertion, that the subject and the predicate are but two different names for one and the same object, or group of objects: every negative proposition is equivalent to an assertion, that the subject is a name for one object, or group of objects, and that the predicate is a name for an object or group of objects different from the first. Besides being universally applicable, this is, of all interpretations of the proposition, that which is most purely formal; and, as being such, it has a peculiar aptitude for logical use. On this reading, the doctrine that affirmation and negation are assertions, respectively, of identity and non-identity, falls back into the class of truisms, if indeed it ever quitted or was in danger of quitting that class. A system of logical doctrines, seeking no further interpretation of the proposition, would be the nearest conceivable approach to a purely formal development of the science. We may often have occasion to recur to this reading, as the readiest means of showing how the special logical laws are only corollaries from the axioms.¹

... αὐτὴ δὴ πασῶν ἐστὶ βεβαιωτάτη τῶν ἀρχῶν . . . ἀδύνατον γὰρ ὄντινόν ταιῦτον ὑπολαμβάνειν εἶναι καὶ μὴ εἶναι. . . διὸ πάντες οἱ ἀποδείκνυντες εἰς ταύτην ἀνάγουσιν ἐσχάτην δόξαν." (*Μεταφυσικά*, iv. 3). "Δεῖ πᾶν τὸ ἀληθὲς αὐτὸ εἶναι ὁμοιολογούμενον εἶναι πάντη. (*Analytica Priora*, i. 32; where the law is alleged as justifying the syllogistic reduction). "Ἀντίφασις δὲ ἀντιθέσις ἥς οὐκ ἔστι μεταξὺ κατ' αὐτὴν μόνον δ' ἀντιφάσεις τὸ μὲν τί κατὰ τινος κατὰφασις, τὸ δὲ τί ἀπὸ τινος ἀπόφασις." (*Analytica Posteriora*, i. 2). The express reference of logical rules to axiomatic principles has been traced to Galen. He, in his treatise *De Methodo Medendi*, states, as examples of such, (*λογικαὶ ἀρχαί*), several axioms, for the explicit treatment of which he refers to his work *On Demonstration*, now lost. Among the instances he gives are these: the mathematical axioms, the law of causality, and the law of excluded middle; "τὸ περὶ παντὸς ἀναγκαῖον ἢ κατὰφάσειν ἢ ἀποφάσειν." (See Prantl, p. 562).

¹ "A proposition is a speech consisting of two names copulated, by which he that speaketh signifies he conceives the latter name to be the name of the same thing, whereof the former is the name, or (which is all one), that the former name is comprehended by the latter." . . . "An affirmative proposition is that whose predicate is a positive name, as "man is a living creature;" a negative, that whose predicate is a negative name, as "man is not a stone." (*Hobbes, Computation or Logic*, part i., chap. iii., §§ 2-6). On this interpretation of the proposition, as a Fact of Naming, Mr Mill, rejecting it as insufficient for founding the strongly objective position he is to take up, makes these remarks:—"The assertion which,

Introduc-
tion.

Let us, in the meantime, test it by an example or two. "All logical doctrines are truths." It is meant, of course, not that logical doctrines are the only truths, but that they are some of those objects we call truths: "All logical doctrines—are—some truths." Plainly, the assertion is resolvable into this other; that the objects which we call "all logical doctrines," are the very same group of objects which we call also "some truths." Our names being assumed to be justified by the fact, every individual thing denotable by either name is denotable likewise by the other: the one group of objects receives two different names, when it is considered from two several points of view. Again, "Logical doctrines are not paradoxes." Here we speak not only of "all" logical doctrines, but also of "all" paradoxes: we assert that the objects we call by the first name are not to be found anywhere among the things we call by the latter. The assertion admits this analysis:—The objects called "all logical doctrines," are non-identical with the objects called "all paradoxes." Each of the objects receiving the one name is an object different from each and all of the objects receiving the other: "logical doctrines" and "paradoxes" are names of two groups of objects, neither of which contains any individual object identical with any individual object contained in the other.

The bearing of the law on propositions considered as predicating attributes and classes.

17. The meaning of a proposition is not exhausted when it is read as a Fact of Naming. Perhaps every proposition has a deeper meaning. This is certainly true of all propositions which assert any knowledge worthy of analysis; and the relations which ground the higher kinds of inference cannot be fully theorized until the analysis is carried further. A name is not given without a reason; and almost every name intimates more or less fully the reason for which it was given.

All the reasons for names are resolvable into our considering of objects as Substances possessing Attributes; and, in respect of such attributes, objects are distributed into Classes, the names of which are Common Terms. The subject may now be itself the name of a group of objects constituting a class or a part of one; the predicate may be the name of an attribute which is possessed or not possessed by those objects. But, since the predicate is itself also a class-name, there arises the further question, whether the class named in the subject is a part only of the predicate-class, or the whole of it, or no part of it at all.

In assuming even the applicability of two names to the same object, we had travelled far from the narrow nook of thought, which gave us, through the pure formulæ, our first glimpse of the developments receivable by the law of non-contradiction. We have travelled yet farther in assuming that each of the names is significant; and, when we regard the names as being, both of them, names of attributes, and through these of classes, we have reached the most cumbersome of the complications under which the question of identity or non-identity can be contemplated.

If we stop short at the point which exhibits the subject-term as being the name of a substance, or of a group of objects considered as substances, while the predicate is re-

according to Hobbes, is the only one made in any proposition, really is made in every proposition; and his analysis has consequently one of the requisites for being the true one. We may go a step further: it is the only analysis that is rigorously true of all propositions without exception. What he gives as the meaning of propositions, is part of the meaning of all propositions, and the whole meaning of some. . . . If, then, this be all the meaning necessarily implied in the form of discourse called a proposition, why do I object to it as the scientific definition of what a proposition means? Because, though the mere collocation which makes the proposition a proposition, conveys no more meaning than Hobbes contends for, that same collocation combined with other circumstances, that *form* combined with other *matter*, does convey more, and much more." (Mill, *System of Logic*, book i., chap. v., § 2).

Introduc-
tion.

garded merely as being the name of an attribute possessed or not possessed by that object or objects, we may appear for a moment to have lost our way. The question, whether an object possesses or wants an attribute, is not very obviously resolvable into the question, whether the subject is or is not identical with the predicate. But even the most common expressions yield this interpretation; and the frequent shortcoming of the predicate—its expression through an adjective—is rapidly supplied, both in thought and in expression, when we take the further step of regarding the predicate as being the name of a class. Both terms of the proposition may now take the form of substantives; both, if common terms, may be taken as names directly denoting groups of objects, and only implying the attributes in respect of which the class-names are given.

If we assert that "All men are imperfect," the full meaning of the allegation is, that all men are a part of the class "imperfect beings;" that, in other words, "All men—are—some imperfect beings." If we assert that "No men are unimprovable," we signify that no men are any part of the class of unimprovable beings; that "No men—are—any beings unimprovable." In the one case we assert that the objects called, when thought of with reference to a certain attribute, "all men," are the same objects which, when thought of with reference to a certain other attribute, are called "some beings imperfect;" in the other case we assert, that the objects receiving the name "all men," are non-identical with "all" the objects receiving the name "beings unimprovable."

In a word, the relation of identity or non-identity, with the determination of thought towards the assertion of either the one or the other, covers all the complications, various as they are, which are made possible through the mutual ramifications of classes, as included one in another, wholly or partly, or as mutually excluded in whole. We have only to presuppose the correlation of Whole and Part (a correlation not arising in the comparison of individuals); to watch carefully, as to each of our common terms, whether as used in our propositions it denotes all, or only some, of the objects denotable by it, or constituting the class it signifies; and to remember that, of each term in its relation to the other, the words indicating whole or part ("all," "any," or "some"), must be thought as integral parts. These precautions being taken, predication through common terms is interpretable as an assertion of the relation of identity or non-identity, with the same ease as that which we find in so interpreting predication through singular terms.¹

18. Exception has frequently been taken to the formal statement of the law of non-contradiction as the one central doctrine of logic. It is not alleged that the law is either deniable, or so much as doubtful; but it is said (and this is the objection most frequently urged), that it is a mere truism, a truth so obvious as not to deserve explicit notice. The necessity of the axioms for the unity of logical science.

The same charge may be brought, with equal fairness, against the geometrical axioms; and these might be treated as the logical axioms have so often been. The truism, the "trifling proposition," that "Things which are equal to the same thing are equal to one another," might be refused a formal place in geometry; and the student might be invited

¹ It is especially to be observed that, when the quantitative signs are accepted as integral parts of the given terms, the identity or difference of the objects is strict and literal. We are thus rescued from all necessity of loosely translating identity and difference into likeness or unlikeness, or of instituting fine distinctions between identity specific and identity individual, between identity total and identity partial; from all those artificial expedients, in short, which have often perplexed so seriously the theory of inference, and made it so difficult to trace the laws of the process upwards to the one central principle.

Introduc-
tion.

to supply for himself it and its fellows, in the demonstration of those initial theorems for which no derivative ground had as yet been laid down. Perhaps the practical evil would not be heavy; but the symmetry and coherence of an exact science would be annihilated.

When the logical axioms are refused their legitimate place, the mischief worked is incalculably greater than any that could arise from a similar procedure in mathematics. There have been constructed very many logical systems, which are quite adequate for the testing of any argument that could be given, and which yet want, not only the formal statement of the axioms, but all express reference to them. A science so treated cannot fail to lose much of that systematic coherence, which is the scientific and philosophical characteristic; and no science loses, through such treatment, more of that character than ours. It becomes an aggregate of rules which are really derivative, but which, not being centralized in their common source, not only exhibit no apparent unity or correlation, but degenerate (a weakness incident to a science so exclusively formal) into mere technical rules, usable and used without conscious reference to any principle at all.

In a word, the construction of logic through secondary laws exclusively, does and must destroy, or seriously impair, its unity as a science. Consequently, there is thus injured, likewise, the evidence of its speculative validity as an analysis of predication and inference. It is yet a worse evil, that this course of treatment diminishes largely the value of the study as a philosophical discipline of thought. In justice alike to the science, and to ourselves its students, unity of system, and consistent development of doctrines, should be steadily aimed at; and it must firmly be maintained that this purpose can neither be reached, nor so much as approximated, unless the law of non-contradiction be expressly laid down as the axiomatic foundation, and unless, also, there be expressly resolved into that law all doctrines whose dependence on it is not self-evident.

Develop-
ment of the
axioms in
reference
to terms
interpretable.

19. It is possible to test the validity of every inference, by a direct analysis of its propositions as assertions of identity or difference. For some of the purposes which the science is designed to serve, such analysis would be quite sufficient. It might, for instance, yield an exhaustive and competent theory of immediate inference. But it would not enable us thoroughly to theorize the syllogism. Syllogistic arguments given might be adequately treated in this fashion; but the character of the syllogism as a representation of several distinguishable processes of thought could not be efficiently displayed, without exhibition of those objective modifications under which the relations of the syllogistic elements come to have place.

With a view to such developments, and also for another reason, the three axioms will here be presented in one or two of the shapes which they may assume, when they are considered with pre-supposition of interpretation of the terms used in propositions.

The other reason is this. The doctrine, that inference is merely an explication of the implied, although it is a truth both undeniable and instructive, is a truth which is far from being palatable. When we are first asked to make ourselves familiar with it, we are apt to forget how mighty is the difference between implication and explication. It costs us an effort to become convinced that the difference is that between obscure thinking and thinking that is distinct—between a thought which is isolated in consciousness and a thought of which we are conscious as an element in a system; that it is the difference between impotence and power, between a cloudy dawn and a sunny noon-day. It is desirable, then, to place this difference in full light.

Now, the contrariety of character between a thought implied in the subject of a proposition and the same thought

Introduc-
tion.

evolved in the predicate, has been anxiously brought out by the framers of those forms of the axioms which are here selected from many others. The concrete character of the cases contemplated in these theorems causes difficulties of expression, which make it desirable to give alternative views, both for avoidance of mistake, and for the suggestion of reflection.

(1.) Whatever is implied in the signification of a term given as the subject of a proposition, may, as predicate, be explicitly affirmed of the subject. Any notion which is implicitly thought in the subject may be explicitly affirmed in the predicate. Of any object or objects denoted by the subject, there may be affirmed in the predicate any attribute consistent with our thought or notion of the subject.

(2.) Whatever is inconsistent with the signification of a term given as the subject of a proposition, may, as predicate, be denied of the subject. Any notion, the contradictory of which is implicitly thought in the subject, may be explicitly denied in the predicate. Of any object or objects denoted by the subject, there may be denied in the predicate any attribute inconsistent with our thought or notion of the subject.

(3.) Of any term given as the subject of a proposition, any other term must be either affirmable or deniable as predicate. Of any object or objects denoted by the subject, any attribute whatever must be either affirmable or deniable in the predicate.

20. It is only for the sake of predication and inference through common terms—for the sake of processes explicative relating the relation between class and class of objects compared in respect of diverse attributes—that logic is worth elaborating into a scientific shape. Knowledge worthy of the name—knowledge the acquisition of which is a duty adequate to the capacities of intelligent beings—knowledge fitting man to act, imposing on him responsibilities, and enabling him to merit rewards—is a knowledge of the attributes of objects, of the laws by which they are governed, of the compass of those several laws, and of the fine and manifold relations in which, through likeness and unlikeness of law, man is placed towards man, and each man towards nature and the Power that governs it and him. Our knowledge of individuals is clear and bright, and shines out spontaneously through intuitions, which dawn on us without our seeking; but the light which thus we see, illuminates a region within which rational life has hardly begun to germinate. Our knowledge of laws is reached only through self-determined energy, through struggles to emerge from doubt, and contentings against error, and slow and painful ascent from height to height of cognition. But, while we do struggle, and contend, and rise, the horizon broadens round us, and our mental vision gains new strength and delicacy from exertion. The idea of law itself passes into that of causality: objects which obey law do so either as causes or as effects. Out of causality again emerges the great idea of purpose; for purpose is preconceived effect, and the efficient cause becomes operative towards this effect as means. Purpose carries us upward, through cause, into the sphere of mind, of thought and will as attributes of beings capable of designing; while here we find ourselves to have adventured into a field of inference, widening our view as we advance, till we have reached the contemplation of one overruling Purpose, of which perceived objects, and discovered laws, and physical causes, and human will, are but the exponents, and consequents, and ministers.

In all the paths which mind can traverse, logical laws are operative as prohibitions guarding against divergence. Logic is concerned, not with the matter of thinking, but only with its forms. Over these, however, it holds exclusive sway. And there is a necessity for the exercise of its powers,—a necessity which becomes the more pressing as the known relations of objects grow wider and more complex. The

Introduc-
tion.

law of non-contradiction could not be violated at all, were it not for the need we lie under of thinking through words, whenever we do think of any thing that is not individual. If every object had but one name, violation of the law would be practically impossible. It is because every object has many names, that the natural course of thinking betrays us into judgments in which the law is unconsciously broken. It is because of the intertwining and often conflicting relations of all thinkable objects, that words are so apt to be used as symbols for thoughts which they do not clearly represent; and the more various and extensive the relations are, the more imminent becomes the danger of self-deception. Therefore it is that logical laws are valuable, not to supply matter for thought, but to test the genuineness of thought, and to protect thinking from being disguised through its expression.

The rela-
tions of
logic to
truth.

21. Logical laws are the scaffolding which gives support to derivative knowledge in the course of its construction. When the structure has been completed, they become for us the plummet and level, through the use of which may be determined the firmness or instability with which it bears on its foundation. But logic does not, and cannot, carry a single stone to the building.

It enables us to explicate, not the relations in which objects exist, but only the relations in which they are thought. The attempt to fix the truth or falsehood of any one proposition given in isolation, is not more palpably extra-logical, than is that of incorporating into the science principles really metaphysical or ontological, that is, bearing on the universal relations between knowledge and existence. This consideration justifies and commands the positive exclusion of all such doctrines as those of the Categories, and of Modality in Propositions. A prohibition which there may be a greater risk of disobeying, is that which excludes all questions as to the objective truth of given classifications, that is, as to the relations actually connecting or separating the objects designated by given common terms. All judgments given for logical analysis, are, for logic, virtually hypothetical. The objects thought as constituting the class may be non-existent; the law through which they are combined may be imaginary; some or all of the objects may be exempt from the law. It is always important, it is often unspeakably so, that we should learn whether it is true that none of these negations has place, and whether therefore a given class-name implies a fact of real and positive knowledge. But this is a question to which, in all its parts, logic stands resolutely silent.

The science must, indeed, look abroad on those objective conditions, those relations between thinking and that which is thinkable, by which the human intellect is fenced in, round and round. But it asks only how those conditions modify the manner of thinking; it takes account of none of them but such as do necessarily determine thinking towards one or another of its only possible forms: and it scrutinizes them for no further purpose than that of eliciting and explaining those forms. When the astronomer looks down from his watch-tower, he is pleased and grateful to see how the sun illuminates the earth, and diffuses life and gladness over the expanse of animal and vegetable nature; but his duty is that of surveying the heavens, and discovering the laws which guide the stars in their courses. With no less satisfaction does the logician perceive that truths, good for man, are revealed in those intuitions on which all thinking rests; but it is no part of his function even to assert those truths, far less to justify or systematize them.

Thus is Logic placed towards all those principles which it either develops, or assumes as given. The correlation of identity and non-identity is itself a law metaphysical as well as logical, a law of existence as well as a law of thought; but it is only in the latter aspect that it is logically import-

ant. So is it as to all those other relations, without the assumption of which the law of non-contradiction cannot be developed. Number, quantity, whole and part, are sufficiently treated for our purpose, when they are regarded as conditions determining the forms in which objects are thought of. Perhaps, again, the relation of substantiality covers, in logic, a wider ground than any other of those modifying conditions. But the most paradoxical or sceptical denials or doubts as to this relation would leave, untouched, the formal view which we have to take of substance and attribute, as being actually correlatives, and thinkable only together, but as admitting of being thought from either of two opposite points of view, which give prominence alternately to the one and to the other.

In short, Logic seeks to develop one principle only—the central Law of Non-contradiction. It develops that law with reference to certain modifying principles: but these it assumes only as given in actual experience, and does not seek to develop; and, further, it assumes them only as being (what they undeniably are) psychological laws, laws regulating thought—declining to inquire into their ontological character as laws of being.

22. The desire of illustrating clearly drives us often, in logical writing or teaching, on exemplification through propositions whose terms have meanings known to those we address. There is a danger in this. The truth or falsehood of each of the propositions being thus known, the mind is allured away from the logical question, whether one proposition does or does not follow from another. Symbolic terms, of the algebraic type, are, in spite of their dryness and repulsiveness, by far the aptest for logical examples.

We cannot see distinctly what the problems are which the science is able to solve, until we consider it as working on materials of this indeterminate character.

Logic neither undertakes nor requires any interpretation of given terms. It is bound to deal with terms which may mean any object whatever, and which are not given as the names of any fixed objects. But no terms can be treated by logical re-agents, unless they are given in a shape that fits them to the crucible. Every term must signify something; and logic cannot deal with terms unless there be given to it the minimum of their signification. The science, like every other, has its *Postulates*.

The Postulates are specified sufficiently, when they are stated with reference to the narrowest data. They are two. Logic must require, as preliminary conditions of its activity, answers to one or both of two queries bearing on every given term. *First*, Is the term singular or common? *Secondly*, If the term is singular, no further information is required. But, if it is common, this other question must be put: Is it in the given case distributed or undistributed?—Is it used in the whole of its extension, or only in a part of it? Both queries bear on the Quantity of the terms, the question which, as we have seen, arises secondarily in logic. If we had to deal only with the Quality of propositions, which is the primary logical question, it would not be necessary to put them.¹

¹ Both of these demands are virtually embraced in Hamilton's *Fundamental Postulate of Logic*: "That we be allowed to state in language what is contained in thought." (Baynes, *New Analytic of Logical Forms* (1850), p. 4). There will hereafter be much of reference to the opinions of that distinguished thinker and profound scholar. Therefore it may be well to say, here, that the present writer's acquaintance with them is derived exclusively from the outline just referred to, which was published with Sir William Hamilton's sanction; from Sir William Hamilton's volume of *Discussions* (1852); from incidental notes in his edition of Reid (1846), especially those on Reid's *Account of Aristotle's Logic*; and from a few observations furnished by him to the last edition (1854) of Mr Thomson's *Outline of the Necessary Laws of Thought*. It is to be hoped that the promised publication of Sir

lates of lo-
gical
science.

Introduc-
tion.

Both queries are, to a certain extent, answered by the forms in which assertions are usually couched, when these have, as in ordinary speech, terms of fixed signification. But, when they are not so answered, the answer must be sought, that it may be incorporated in the expression of the terms. Singular terms require and receive no Quantitative Signs. Common terms do require either "all" ("any") or "some," and should have the one or the other, whether they be subjects or predicates.

The postulates are reasonable. They do not stretch a step beyond those two objective conditions (individuality and universality), by the one or the other of which actual thinking is formally modified. The logician is bound to provide laws applicable to terms whose meaning is as arbitrary as that of algebraic symbols. But the algebraist, too, has his formal postulates. His a, b, c , and x, y, z , are thus far fixed in signification, that all of them denote numbers; and he is warned, by pre-arranged marks, whether the numbers are integers, or fractions, or powers. Our terms, even though symbolic, are thus far fixed in signification, that they must denote possible objects of thought, and objects thought under one or another of certain conditions. In demanding what the given conditions are, we ask for explanations exactly parallel to those which are allowed to the mathematician. No narrower pre-information will suffice, if logic is to be anything better than a theory of dreams.

The formal
limits of
logical ana-
lysis.

23. The postulates being granted, let us ask, lastly, what data, furnished with them, give a hold to laws purely logical. The relations of common terms are the only ones with reference to which it is worth while to generalize the cases.

First, The narrowest datum on which logic can work without foreign aid, is one proposition,—the assertion, through a copula, of identity or non-identity between two terms quantitatively determined. From such a datum, the science can regulate and justify the evolution of certain other propositions by Immediate Inference.

Secondly, Logic can work with incalculably greater freedom on two propositions given. These are data for the normal form of Mediate or Syllogistic Inference. (1.) The data may not yield, by inference, any third proposition. If so, the reasons of the failure can be shown. (2.) The data may yield, by inference, a third proposition. If so, the science can direct the evolution of that proposition, and assign reasons both why it is evolvable, and why no others are so. (3.) While, in both cases, the reasons are ultimately traceable to the logical axioms, it can be shown, through derivative laws, that the result depends immediately on the question, whether the given terms do or do not constitute a series, related to each other both in Extension and in Comprehension.*

William Hamilton's Lectures will speedily furnish information, of which, in regard to points not a few, the students of his masterly logical system are still very much in want.

* Something, perhaps, should here be said, of the reasons which have seemed to justify the raising, in the present chapter, of questions in regard to the function and limits of logical science. Few or none of these needed to have been touched on, if it had been sufficient to regard logic exclusively from the practical side. All of them (and, it may be, others also) imperatively demand attention from those who would form a right estimate of logic as a system of speculation,—those who would know what value it has in itself as an exposition of the regulative theory of human thought.

In this country, there has never been seriously contemplated the possibility of a Logic absolutely pure or *à priori*, that is, of a system of logical science not only thoroughly demonstrative in its deductions, but not acknowledging even any data that are empirical. The possibility was broadly averred by Kant; and the endeavour was made to work it out in not a few German works, among which may be named especially those of Kiesewetter and Hoffbauer, and the symmetrically systematic treatise of Twisten. Gradually it came to be perceived, that even the ablest thinkers who had taken up this position, had not been able to proceed a step without silently assuming empirical or psychological data. Those earlier writers who exhibit-

Introduc-
tion.

ed the fullest proofs of this assertion were Troxler and Bachmann. The attack on the Kantist limitation of the sphere of logic was next undertaken, on much deeper philosophical principles, by the same energetic iconoclast, of whom, not very long ago, Rosenkrantz complained, that he "had brought philosophy (that is, Hegelism) to a stand-still." In Trendelenburg's *Logische Untersuchungen* (1840), every inch of ground was cut away from under the feet of those logicians who aimed at constructing the science without presuppositions. Yet the writings of this singularly acute and learned controversialist are not the only symptoms indicating that, in Germany itself, the reaction has issued in an oscillation stretching equally far from the truth on the other side. It is not easy to see how Trendelenburg himself could frame, in consistency with his leading opinions, a positive theory of predication and inference which should be anything else than a hybrid generated between logic and metaphysics. The instructive treatise of Drobisch, also (*Neue Darstellung der Logik*, 2d edit. 1851), incorporates objective elements so freely, and brings them to bear on the formal laws of thought with such intimacy of relation, that the latter are fairly overbalanced, and the science ceases to be operative as yielding readily practical tests for explicative thought.

But Drobisch's mode of working out the details does seem not to be necessitated by his own opinion as to the function of the science. A paragraph of his preface, explaining that opinion, may serve to illustrate the position which, here and afterwards, it is endeavoured to make good in the text.

"Trendelenburg says, of the formal logic, 'that it desires to understand concept, judgment, inference, from the self-referred activity of thought; that hence it separates thinking from its object, as if the mirror which receives the light were separated from the ray which falls on it; but that such separation is hazardous, since the law of reflection is not conditioned by the mirror alone.' This view is incorrect.

"Formal logic does not presuppose a pure thinking, and does not undertake to analyse or develop the forms of such thinking in the abstract. Its presupposition is that concrete thinking which is in the most intimate union with cognition. From such thinking, the science, through abstraction, gains its fundamental forms; and then, according to the laws yielded by consideration of the relations of the forms, it connects the forms with each other, and thus reaches derivative forms. Forms without matter or content logic does not know; it knows only those forms which are independent of the special matter that may be placed in them, and for which, therefore, the matter, although it can never be dispensed with, remains indeterminate and accidental.

"The fundamental forms of thinking are gained in a manner like that which yields the fundamental forms of geometry. These are only the remainders, which abstraction leaves over from the physical and chemical properties of bodies perceived through the senses. The idea of empty space is an abstraction, foreign both to sensuous intuition and to its reproduction in memory; the geometrical surface requires a second abstraction; the line and the point require a third and a fourth. In like manner does logic arrive at the concept, its marks and its relations. But geometry is not contented either with the discovery of the fundamental forms, or with the classification of corporeal forms as presented by experience: through combination of the fundamental forms, it reaches ideal constructions, in which indeed it partly reconstructs that which is given and actual, but partly comes on formations which appear to us like strangers in the known world of sense. In a manner exactly similar—in the doctrines of judgment and inference, of divisions and proofs—does logic deal with the fundamental forms of concepts; while it allows itself to be guided by nothing but the consistency of the forms of thought with each other, the consistency of thinking with its own principles. This consistency is the only logical truth."

Of recent English works, two should be particularly referred to, as placing the function of logic on a solid and philosophical basis: to both of these more obligations than one are here due: Mr Karslake's masterly sketch, the *Aids to the Study of Logic*, book i.; "Pure Analytical Logic" (1851); and Mr Mansel's treatise, alike acute and comprehensive, the *Prolegomena Logica* (1851). Much of valuable suggestion in regard to principles is furnished also by Mr Chretien's *Essay on Logical Method* (1848). Mr Moberly's *Lectures on Logic* (1848) may be advantageously consulted for several points of special doctrine; and Mr Kidd's *Delineation of the Primary Principles of Reasoning* (1856), is exceedingly instructive, both in its original matter, and in its analytic comparison of recent logical systems.

This may be as fit a place as any, for alluding to the mathematical theories of thought, of which several have been propounded by actively thinking men, both in other days and in our own. Some of these have been content with expressing logical doctrines and rules in mathematical forms: others have insisted on seeking the foundations of logical science in principles really mathemati-

Doctrine of terms.

To the valuable German treatise just quoted from, there is annexed a "Logico-Mathematical Appendix," in which long and complex trains of reasoning are designated by algebraic symbols. The reduction of all thinking under an elaborate series of symbolic formulæ is the design of an exceedingly subtle and able work, Dr Boole's *Investigation of the Laws of Thought* (1854). In Mr De Morgan's *Formal Logic* (1847) the practical side is often approached very closely, and the pure laws of thought are developed in several of their relations with very great skill; but the principles of logic are thoroughly subordinated to those of mathematics.

All attempts to incorporate into the universal theory of thought a special and systematic development of relations of number and quantity, must be protested against with equal firmness, whichever side of the question we may look to. If the systems are to be estimated speculatively, as philosophical expositions of the laws which regulate all thinking, it must be said that they are faulty both by defect and by excess. They endeavour to theorize all thinking, by examining thought only as exerted on one kind of objects: they allege, as bearing on thought universally, laws which rule it only in certain cases. If, again, the systems are supposed to furnish rules avail-

able for practice, they must be pronounced to be both unnecessary and ineffective; and this objection lies, not only against the intrusion of mathematical principles, but also against the adoption of mathematical forms for any purpose beyond that of incidental illustration. No cumbrous scheme of exponential notation is needed, and none such is sufficient, for the actual guidance of thought when its objects are not mathematical: when its objects are so, the science of mathematics is both bound, and is the only science that is qualified, to yield the principles on which rules may be founded. The question may be considered, also, with reference to the value of logical study as a discipline of the mind. Now the mathematico-logical theories tend, one and all of them, and tend the more strongly the nearer they bring their rules towards the forms of the higher mathematics, to convert logical study into a mere cramming of the memory with formulæ, and logical practice into a mechanical manipulation of rules not known to have reasons. Even in its genuine shape, the science is, on account of its formal character, liable to both of these dangers; and the duty of its expounders is to guard against them, not, certainly, to run wilfully into their way.

Doctrine of terms.

PART FIRST.—THE DOCTRINE OF TERMS.

The signification of terms, singular and common.

24. We have already learned that, and how, the two aspects in which objects may be regarded, as individuals or as members of a class, impose on judgments and propositions the only objective modifications to which they are universally subject. The Terms through which objects are thought must be either Singulars or Universals. It remains only, in reference to terms considered as elements of judgment and predication, to place their characteristics in the position in which they are directly available as the foundation of logical rules. Here the principal question is that of the manner in which both images and concepts, and also the relations of these to each other, are denoted by words.

Singular terms call for little examination. Common terms must be scrutinized very exactly; both by reason of the difficulties they involve, and because inferences through them, being the highest formal developments of thought, are the processes whose laws constitute the highest sections of logical doctrine.

For almost all-logical purposes, it is sufficient to consider terms as the Names of Objects of Thought. Singular terms are thus names of objects thought of as individuals; common terms are the names of classes thought of as constituted by individuals or kinds of individuals. But we must always hold ourselves prepared to fall back, when it shall be necessary, on these two limiting facts:—first, that logic, both in assuming data and in working out results, has regard, not to the question whether objects are real, but only to the question whether and how they are thinkable and thought of; secondly, that terms denote objects only as thought of under some given relation.

The words which constitute terms.

25. The relations under which we can think of objects may be either comparatively simple, or indefinitely complex. Further, the expressibility of a relation in few words, or its requiring of many, may frequently be determined by circumstances extraneous to the character of the relation.¹ Therefore, a term may consist either of one word, of several, or of many. But its one word, if it has no more, or its leading word—that which expresses the most prominent idea of a group—must, admittedly, in the first place, be a noun, either substantive or adjective; and, next, it may rightly be held, that a common term does not bring out completely the concept of which it is a sign, unless its one word or leading word is specifically a noun-substantive. An adject-

tive, indeed, does often do duty as a predicate; but a substantive is required for giving easy and full expression to an idea constituting a subject. Now, a given proposition is not adequately developed, unless it has a form enabling us, without interpolation, to extricate from it all its possible results; and some of these results are not attainable unless through transposition of the terms.¹

26. We must now note, in a general way, the manner in which the singular and the common term severally signify the individual and the class.

(1.) Nouns may denote individuality in any of several ways. They may be proper names; as of persons or places: "Napoleon, Socrates; England, Edinburgh." Only it should be noted that, names of persons having long fallen short of the demand, many or most of such words are really common terms, though interpreted as singulars, through our knowledge of the circumstances in which they are used. The words, again, may be words which are strictly common terms, but whose meaning is individualized by the accompaniment of definitive descriptions: "The man whom I saw yesterday;"

The manner of signification of words constituting terms.

¹ A word or phrase which may by itself be a term, is said to be Categorematic (*κατηγορηματικόν*, to predicate); one which cannot, is Syncategorematic. By a noun is meant a noun in its nominative case: the oblique cases are excluded, with all other parts of speech. Many logicians take this distinction; that a substantive is required as subject of a proposition, but that an adjective may be logically accepted as the predicate. According, however, to the view stated in the text, such an expression as "Some men are good," is elliptical, and should, for logical treatment, be explicated into "Some men are good persons." In such fillings-up, we are doubtless exposed to the risk of limiting the predicate to a meaning narrower than the datum; but this is not difficult of avoidance. There are strong reasons for insisting on the doctrine, that substantives are the only parts of speech truly categorematic. "The predicate as predicate carries with it the mark of dependence; it does not become a free concept, till it assumes the form of substance, and may in this form become subject." (Trendelenburg, *Logische Untersuchungen*, ii. 144; see also Ritter, *Abriß der Philosophischen Logik* (1829), p. 68). When we set about bringing logically to light the relations of given terms, we are not entitled to suppose that each of our terms will continue to discharge the function it had in the proposition which gave it to us; and we are bound, in setting forth our data for logical manipulation, to give to each of their elements a form which shall bring out its character as fully as possible, and qualify it for discharging any function which any possible variety of inference can impose on it. The imperfection of the evolution which the adjective yields is exposed as soon as we attempt logical conversion. The example, as above expanded, furnishes at once the converse,—"Some good persons are men;" but, as first set down, it would not yield any intelligible converse, unless either the substantive were interpolated in the process, or the proposition thrown into one or another of those abstract shapes, which, as we shall see, are almost utterly unmanageable.

¹ Very many short or simple terms, both ordinary and technical, imply ideas which are exceedingly complex. Such terms are conventional abridgments, adopted for the acceleration of thought, as well as of speech; and they are of constant occurrence as names of objects possessing universal interest and importance. They carry with them both advantages and dangers.

Doctrine of terms. "the meadow which lies before my window;" "the argument by which you convinced me." Nor will a term be the less a singular, though the descriptive addition be by itself insufficient to indicate, or may even leave it uncertain to the speaker himself, what individual it is meant to designate. "Yonder hill," may require a gesture to determine the one hill intended; "the most profound philosopher of our age," may be a name for a person undetermined by those who use the phrase.¹

Another class of cases is more apt to be mistaken. A thing is thought of as an individual, whenever it is thought as one object, although its unity should be made up of several or many individual parts; and any given individual may itself be next thought of as a part of some other thing, which in its turn is thought of as an individual. Thus, among objects of perception, we may think successively of "that trunk, that tree, that forest:" and so, likewise, may it be for phenomena of reflective consciousness:—"The idea I have at this moment, the judgment of which that idea was an element, the course of reasoning in which that judgment was one of many steps." Examples like these, which would fall under the scholastic description of an integral whole, are not the only ones. Even the logical whole, that is, the class constituted by the individuals designated by the common term, may itself be abstractively thought of as one object. The distributive all (= each), leaves the common term as the sign of a true concept; the collective all (= all taken together), transforms it into the sign of an individual unity.²

(2.) In regard to the manner of signification in common terms there is required one remark only. Common terms are the names of classes, constituted, either immediately or through intermediate steps, by individuals, which are thought of together in respect of their possession of certain common attributes. Sometimes the term distinctly states the attribute; but, even so, the objects or substances continue to be, in speech as in thought, more prominent than the attributes. Much more frequently, and especially when the objects constituting the class are many, the common term is an arbitrary name, which briefly, but directly, denotes the class, and is applicable to each and all of the objects, while it merely implies or connotes the attributes. Indeed, both in common life and in science, it is much oftener easy, from a large combination of obvious characteristics, to place objects in a certain class and give them a conventional class-name, than to fix with strict accuracy the attributes which are essential and peculiar to the class.

The quantity of terms.

27. Out of the essential distinction between the two kinds of terms, there arises a broad distinction in the manner in which they are severally usable.

Individual objects are thinkable only as indivisible units. Consequently, a singular term can never, without altogether losing its character, denote anything less than the object of which it is at first assumed as a name.

Classes of objects, on the other hand, may be thought either in whole or in part. We may think, either of all the objects constituting the class, or only of fewer than all of those objects; and we cannot think the concept, or use the class-name, otherwise than for thinking and expressing either the one or the other of the two alternatives. A common term *may* be understood as denoting all the objects of the class; it *does*, in every proposition, denote either all or fewer than all of them.

¹ An object indicated thus indefinitely was called by the old logicians an *individuum vagum*. It was a disputed point whether the term denoting it were properly a singular, or a common term used particularly.

² See, among other explanations, that of Wallis, *Institutio Logica*, part i., cap. ii.

Doctrine of terms. A common term, when it is used to denote all the objects of the class, is said to be taken Universally, or to be *Distributed*; that is, to be spread over the whole class, or to be applied to all the objects distributively, not collectively—to each, not to all together. A common term, when it is used to denote fewer than all the objects of the class, is said to be taken Particularly, or to be *Undistributed*.

A common term, therefore, may, in a useful sense, be said to have *Quantity*; its quantity being variable, as universal or particular. It is scarcely correct, and not at all useful, to consider a singular term as having quantity. When it is said that a singular term is equivalent to a common term distributed, all that is meant is, that it does not admit of non-distribution or particularization.

We must be able, then, whenever a common term is given, either to assume or to infer whether it is distributed or undistributed. The state of the fact is, for the subject at least of a proposition, indicated in common language, by a variety of prefixed phrases. Two of these are, for convenience, used always in logic; and, it may here be observed, the signs should, for logical working, be prefixed to the predicate as well as to the subject.

28. The ordinary Signs of Distribution³ are fully interpretable for us, because the universality of terms has no degrees, and is Definite. The number of individuals contained in a class may indeed be, and almost always is, indeterminate; but, be they few or many, we do, in distributing the class-name, definitely embrace all of them under it.

All logicians adopt, as the sign of distribution in affirmative propositions, the one prefix "all" or "every." Some adopt it for negatives also; but such a use of it is apt to mislead. In the expression "All X's are Y's," the subject is understood by every one to be distributed; but in "All X's are not Y's," most persons would interpret the sign as intimating non-distribution.⁴ It is safest not to incur the risk. It may be avoided by using the prefix "any" in negation. This sign is useable without any difficulty for the predicate; and it is best to use it as a prefix for the subject also. If there is thought to be a needless awkwardness in such phrases as "Any X's are not any Y's,"⁵ we might content ourselves with an indesignate subject, and say, "The X's are not any Y's;" a form which by most hearers would be interpreted as distributing the subject, while it may, at all events, be taken in that sense by agreement.⁶

The signs of the distribution of common terms.

¹ They are such as these: "all, every, any, whatever." Both of the articles, too, are so used when joined with ampliative phrases; as, "The man (or a man) who has true self-respect, is not likely to refuse due respect to others."

² "All X's are not Y's," is naturally understood as being merely a denial of the assertion that all the X's are Y's; as equivalent to this: "It is not true that all the X's are Y's." But we are entitled to make this denial, if it be true that even "Some of the X's are not Y's," or that "There is some (or any) X which is not a Y;" and this is all the meaning we commonly attach to our "All X's are not Y's." In so interpreting it we are, as in numberless other instances, working out logical doctrines without being aware that we are doing so. "Some X's are not Y's" is logically the contradictory of "All X's are Y's," that is, a proposition necessarily inconsistent with it.

³ Ordinary language would give this arrangement:—"Not any X's are Y's;" and this again would pass into "No X's are Y's." These forms, and especially that which both displaces and incorporates the negative sign of the copula, are apt to tempt us into mistaking, for a moment, the quality of the proposition, and supposing it affirmative. The alternative afterwards proposed has the opposite fault: it conceals the quantity, and might lead us to suppose the proposition particular.

⁴ Propositions whose subject has no prefix of quantity are usually called Indefinite, more properly (Hamilton) Indesignate. The subject, if a common term, must necessarily be either distributed or undistributed; and logicians are wont to say that we cannot decide which of the two it is, until we have interpreted the terms, and considered the matter of the judgment. But, when such

Doctrine of terms.

The signs of the non-distribution of common terms.

29. The ordinary Signs of Non-distribution¹ are not fully interpretable for us. Each of them, besides directly signifying particularity, does also denote or imply some closer specification; and the particularity is the only part of their meaning that yields an idea logically available.

The only quantitative distinction with which a universal theory of thought can deal, is the all-pervading distinction between "all" on the one side, and "not-all," or "fewer-than-all," on the other; between a whole on the one side, and, on the other, something of which we can say only that it is some part or other of that whole. Accordingly, all the ordinary signs of particularity must, so far as logically cognizable, be taken as equivalents; and, for convenience, all of them are translated into the technical "some." Were it not that even one of the parts of the logical whole is enough to let in the logical "some," it would be exactly parallel to one popular phrase. Our "Some X's are Y's," were it not that it might possibly mean only "One X is Y," would be equivalent to the assertion, "There are X's which are Y's."

The true character of Logical Particularity requires to be very precisely understood. It is in all respects Indefinite.

(1.) In the common use of words, a proposition introduced by any of the limitative signs is (unless accompanied by an explanation) understood naturally and fairly as a proposition implying another. Our usual "some" means "some, but not all;" or, "some at most." If we explicitly assert that "Some are —," we are understood as implying that "Some (or many) are not —." No man asserts merely of "some" if he might assert of "all."²

The "some" of logic is equivalent to "some at least;" "some, it may or may not be all." And why? Because this is the minimum of signification bearable by any limitative sign of quantity. So much as this must be signified by each of them; so much may be assumed as involved in every assertion of the sort; and if, in a given instance, more is signified, the overplus may and should be treated as a separate proposition.³

(2.) All the ordinary signs are more or less definite in their reference upwards to the whole class: they hint at or tell of a proportion borne by the part to the whole. Some of them leave that proportion quite uncertain; others describe it vaguely; and others specify till they reach numerical determination.

The logical "some" utterly ignores such reference. This

a proposition is negative, probably no man would dream of interpreting it particularly; and even when it is affirmative, we do certainly tend to give the same interpretation. On common talk, or on oratorical or poetical effusion, it would be unreasonable to impose very severe restrictions. But in argument it would hardly be unfair to insist on interpreting universally, as against an opponent, every indesignate proposition he adduces. A reasoner who expresses particular assertions without explicit limitation, must do so either because he designs to be ambiguous, or because he thinks confusedly, or because he is (perhaps unconsciously) suppressing some step of reasoning which it would be right to force out into explicit statement. Sanderson places such assertions among his "Suppositiones," or propositions implying others; and he interprets his example as a disjunctive: "A ship is necessary for crossing the strait; that is, this, that, or the other ship is necessary." (*Logica Artis Compendium*, lib. ii., cap. 2.)

¹ Some, a few, a very few, few (= many not), a great many, not a few (= many), most, a small, large, or considerable number, a majority, a minority, a small or large proportion, nearly all, all but a few, more or less than half, &c.

² If I say, in common phrase, that "Some men are wise," I am understood to imply an opinion, that some men, or many, are not wise.

³ If I use the "some" in its logically restricted sense, and thus design to convey no implied meaning at all, I may say that "Some men are mortal;" since I know that "All men are mortal," an assertion by which mine is covered. If I were to speak with implication of the usual *anneum*, my reason for saying that "Some men are mortal" would be, that I hold some or many men not to be so.

is plain from the explanations already given. If the number of objects in a class were exactly ascertainable, our "some" would be broad enough to cover all of them but one, and narrow enough to admit one and keep out all the rest.⁴

(3.) Of the ordinary signs, some are definite, others quite indefinite, in their reference downwards towards the objects constituting the class. "Certain men (*quidam homines*)," is an example of the first kind; "Some men or other (*aliqui homines*)," belongs to the second.

The logical "some" is totally indeterminate in its reference to the constitutive objects. It is always "*aliqui*," never "*quidam*": it designates some objects or other of the class, not some certain objects definitely pointed out.⁵

Both the second rule and the third seem to grow out of a consideration which may be explained thus. By making our quantitative limitation definite in either direction, upwards or downwards, we should really have thought out a new class, constituted by so many of the objects as we had thought of or named. The common attribute of the class would be the fact that the objects are so specified by us. And all so specified by us being signified by the term (say, "some certain X's"), this term would really, paradoxical as it may appear, be a common term distributed. It would be equivalent to "all those X's I am thinking of."

² Whenever particularity is carried, though it were but by a single step, beyond, the negation of totality ("not-all"), we have passed out of the sphere of logic into that of arithmetic or mathematics. Number, it is true, is a logical *præcognitum*. But the positive ideas which logic postulates under it are only unity, plurality, and totality; and, specially, it postulates plurality only as being in thought the necessary link between unity and totality. It does not seek to develop plurality, positively, into any of those indefinitely various specifications which the repetition of the unit makes possible. When logic does aim at such development (and some very able logicians have tortured it into the task), it attempts what it cannot and need not do. It sets about performing, clumsily and imperfectly, a duty which the appropriate sciences of number and quantity execute with promptness and perfection.

So long, indeed, as the proportional specifications of particularity remain very vague, arithmetic and algebra give assistance so slight, that problems of the sort, though insoluble by pure or universal logic, are fairly and conveniently assignable to logic mixed or applied. Many such problems fall directly, or may easily be brought, within the scope of the rules given by logicians for modal propositions. Others are so easily dealt with as to require no rules beyond those of common sense. The premise "Most of the X's are Y's," evidently allows a wider inference than the premise "A few of the X's are Y's." As soon as we move on beyond such a point as this, we are, if we insist on continuing to use logical forms, doing really nothing more than throwing into logical forms results which we have gained by previous calculations, arithmetical or algebraical. This is true even of the simplest and most ingenious of all the devices of the mathematico-logicians;—Mr De Morgan's principle, called by Sir W. Hamilton the "ultra-total quantification of the middle term." The principle is this: that a half, and anything more than a half, are together in excess of the whole; and it yields a formula which merely saves us the trouble of working a simple equation, having oftentimes an indeterminate solution.

³ This third point, though implied in several of the received logical rules, has sometimes been overlooked. Surely it was so by those of the old logicians, who gave "*quidam*" as the logical sign. One or two of the Germans complicate the theory of predication needlessly, by admitting both readings.

Compare these two propositions: "Some X's are Y's;" "Some X's are not Y's." The popular "some," when unqualified, is naturally understood as indefinite; therefore common sense would lead us to say that, for all we know, both propositions may be true, but that the one or the other of them must be true. Logic, understanding the quantity of both X's as limited indefinitely, gives the same verdict. But sense and science would agree in granting a new trial, if the subject were, both times, "some certain X's." We should then have to call for evidence showing, whether the X's selected in the first proposition are the same X's which are selected in the second; or whether the two subjects designate two different sets of X's. If the sets are the same, one of the propositions must be false. If the sets are different, neither the truth nor the falsehood of the one would entitle us to infer either the falsehood or the truth of the other.

Doctrine of terms.

Doctrine of terms. Definiteness, in short, is the distinctive characteristic of universality or distribution; indefiniteness is that of particularity or non-distribution.¹

Development of the extension of common terms.

30. We must now treat, more closely than before, both of the relations, the objective and the attributive, which together constitute the totality of the concept, and of its sign the common term. Out of these will emerge by degrees one logical doctrine after another, till they yield at last their highest results in the theory of the syllogism.

The reference made by a common term to the objects thought as contained in the class, is called the *Extension*, Sphere, or Compass of the term: or, otherwise, the extension, sphere, or compass of a common term may be said to be constituted by all the objects thought as contained in the class.

In the broadest view, therefore, the extension of a common term is constituted by all the individual objects; and in any more limited view we can take, this ultimate reference to the individuals is silently implied. But the affirmation of extension by an enumeration of individuals, would be seldom (if ever) possible, and always useless. Every common term presupposes, in one view or another, several or many steps of generalization. Thus it has under it other common terms denoting contained classes of objects; while each of these may have other common terms under it; and so on, it may be, through many stages. When, therefore, common terms only are compared in respect of extension, the Extension of a Common Term is said to be constituted by all those other common terms, which are the names of classes or kinds of objects thought as included in the class denoted by it. Thus, one common term may have its extension constituted directly by several other common terms; each of which, again, has its extension constituted directly by several others: and, of course, the extension of the first covers all the extensions of all the others.

Concepts or common terms may be said to be *Ordinated in Extension*, when they are arranged in an order corresponding to the steps of generalization or specification. Ordination is most conveniently made from highest to lowest,—that is, from the one widest class, which contains all the others, down to the one or more narrowest classes, in which the data do not allow us to include any others. In respect of extension, we descend in the order of specification. The highest or most extensive term in such a series is said to be *Superordinate* to all the others; terms yielded by one and the same step of generalization or specification are *Co-ordinate*; every term lower than the highest is *Subordinate* to all terms whose extension is greater, while it is *superordinate* to all, if there are any, whose extension is less. There are used also, as descriptive of ordination in extension (not in comprehension), the names *Subalternant* and *Subalternate*; to which there should be, and sometimes is, added, the name *Co-alternate*.²

It must be noted very particularly (though the point was observed before), that, as we descend in extension we are, at every step, thinking *away* objects, but thinking *in* additional attributes; that, as we ascend in extension, we are thinking *in* objects, but thinking *away* attributes.³

¹ Consult, as to all the quantitative signs, Hamilton's *Discussions*, the Logical Appendix.

² Thus, let us, assuming terms whose meaning and relations are simple and obvious, start from the class "organized beings" as a superordinate. One step lower in specification gives us, as the two classes constituting that class, "animals" and "vegetables," which are therefore subordinate to the first class, co-ordinate with each other, superordinate to any kind we may place under either. If, neglecting the class "vegetables," we descend in a loose specification with the term "animals," it might give us the six classes, "men, beasts, birds, fishes, reptiles, insects;" and these classes would be, all of them, subordinate directly to "animal," indirectly to "organized being;" they would be co-ordinates of each other; and, if our specification stop here, they would have no subordinates.

³ Thus, our example sets out, in descent, from an indeterminate

31. The reference made by a common term to the attribute (simple or complex) thought as possessed by all the objects of the class is called the *Comprehension*, Intension, or Content of the term: or, otherwise, the intension, comprehension, or content of a common term may be said to be constituted by the attribute (simple or complex) thought as possessed by all the objects.

Doctrine of terms. Development of the comprehension of common terms.

If a term given to have its comprehension evolved, presupposes but one step of generalization, the attribute is simple, or one; and no further evolution is possible than that which is yielded by the immediate import of the name. But each additional step of generalization gives an additional element to the attribute, which thus becomes complex; and each of these steps yields a new common term, the statement of which is a step in the evolution of the comprehension of the given term. Common terms which thus evolve the comprehension of a given common term, may be said to be terms signifying attributes which are implied in the attribute given; or they signify attributes in respect of which the objects constituting the given class may be thought of as being included also in some other class or classes.

Cases yielding no possibility of evolution being excluded as barren, the Comprehension of a Common Term is said to be constituted by those common terms, which are thus significant of implied attributes. These are often, with suggestive propriety, called the *Marks* of the given term or concept.

Suppose, now, that there is given to us a series of terms ordained in extension; and that we are called on to find among these the terms which are the intensive or attributive marks of some one term of the series. In what direction shall we look?—upwards or downwards?

The attributive marks must, all of them, be possessed by all the objects of that class of which the term whose comprehension is sought is a name. Consequently, the marks of the term will not be found in any one of the terms lower or less extensive than it is; for each of these lower terms signifies some attribute, possessed, indeed, by some objects of the class we start from, but wanting to others.

The marks of a term must be sought among the terms more extensive than itself. The objects of the given class possess the attribute signified by the term whose marks we seek: they possess also some other attribute, which is possessed by other objects besides; that is, they possess also some attribute in respect of which the given objects and these others are included in another class, which accordingly is more extensive than the first. The name of this more extensive class is a mark of the given class, in so far as it signifies an attribute possessed by all the objects contained in that class.¹

but large number of beings thought of as possessing the one attribute of "organization." At our next step, whether we regard the one term or the other in the co-ordination, we have a class containing fewer objects. For "animal" and "vegetable" together are required for including all "organized beings;" and each of the two classes wants all the "organized beings" contained in the other. But, contrariwise, whichever of the two subordinate classes we contemplate, we see that its constitutive objects, though fewer than all "organized beings," possess an attribute which is not possessed by all organized beings, and is not the attribute on the thought of which the class was founded. "Animals" have the special attributes constituting "animal life;" vegetables have the special attributes constituting "vegetable life." It is needless to carry the analysis through the third stage.

The character of the ordination might be perceived from a different point of view, if we were to substitute, for each of the terms, its contradictory. "If negations are joined in thought to two concepts relatively higher and lower, there arises thus a reversal of their subordination. For, through the concept which contains the negation of a species, more objects may be thought than through those concepts which make up the negation of the genus." (Schulze, *Grundsätze der Allgemeinen Logik*, 1831, p. 54).

¹ Thus, the series of the last section does not yield any mark of the term "organized being;" no one of the lower classes signifies

Doctrine of terms. Common terms may be *Ordinated in Comprehension* as well as in extension; and it appears plainly, that the order in the one case must be exactly the reverse of that in the other. If arranged from highest to lowest, they will now stand in the order of steps in a presupposed generalization.

Again, to a series ordained in comprehension there may be applied the same set of comparative names which were applied in the former ordination:—Superordinate, Co-ordinate, Subordinate. But, while co-ordinates continue to hold the same place, the terms which before were superordinate have now become subordinate, and contrariwise.¹

It is manifest, likewise, that, terms being given as expressly ordained, either in extension or in comprehension, the other ordination is given by implication.

The law of concepts and common terms.

32. The results now gained enable us to generalize the distinctive law of concepts and common terms.

Extension and comprehension stand towards each other in an inverse ratio. By how much the more (or fewer) objects a class is thought as containing, by so much the fewer (or more) attributes are the objects thought as possessing: by how much the more (or fewer) the attributes are, by so much the fewer (or more) are the objects.

For predication through common terms this is the universal Quantitative Law. Such predication, governed primarily and qualitatively by the principle of non-contradiction, is governed secondarily, and in the way of quantitative restriction, by this law of inverse determination.

All such predication may correctly be said to be nothing more than an explication, in the form of judgments and propositions, of those relations between the terms, which are implied in a pre-formed ordination. The same assertion may be made as to inference: for inference is merely a series of predications or propositions, in which implied relations are successively and systematically evolved.

The abstractive separation of the two wholes of the concept.

33. There is one limitation, narrowing our use of the determinative law of concepts when we come to use it in predication. To this limitation our attention cannot be too early called.

The concept, that which a common term signifies, is thought as a whole, whose parts also are thinkable. It has parts both of extension and of comprehension: it has parts when it is considered in its relation to objects; it has parts when it is considered in its relation to attributes. Its totality is constituted by both kinds of parts taken together, not by either kind independently of the other.

If we are to think the concept, that is, the whole of signification of a common term, without any attempt at evolving the parts of either kind, we may and must think it as a whole whose constitution implies parts of both kinds.

But, if we desire to find the parts, or any of them—to determine what the parts are, and to think them, or any of

them, distinctly—we cannot do so in both relations at once. **Doctrine of terms.** We must seek, either to evolve the parts of the extension of the common term, leaving the comprehension unevolved as given, or to evolve the parts of the comprehension, leaving the extension unevolved as given. The complete evolution of the signification of a common term X, is a task to be performed only by the working of two problems, which must be solved separately. We must evolve the sphere, or extension, by determining what are all the kinds of X's, while we take for granted the attributes common to all the things so called; and we must evolve the comprehension, by determining what are the attributes common to all X's, while we take for granted the compass of the objects which bear the name. We must either think explicitly in extension, while we imply comprehension; or think explicitly in comprehension, while we imply extension.

While, therefore, a concept is one whole, yet, in reference to the possibility of abstractive analysis, its totality may be and by logicians frequently and conveniently is, said to be constituted by Two Wholes. A concept, or its sign the common term, is evolvable so far only as it may be regarded as involving, on the one hand, a whole of extension constituted by objects, and, on the other hand, a whole of comprehension constituted by attributes.*

* The whole of extension has often been called the "logical whole;" and the whole of comprehension has, by some of those logicians who have generalized its laws, been said to possess the character assigned, by others than logicians, to a "metaphysical whole." The names point to a distinction worth noting.

Yet the warning must be added, that they will deceive if they tempt us to infer the exclusion of comprehension from logical scrutiny. The warning is the more needed, because this aspect of the concept is by far the more difficult of the two, both for thought and for expression; and because in our logical systems the weakest point is the development of it.

So much of doctrine will hereafter be founded on the correlation of extension and comprehension, that it may be well, once for all, to bespeak close attention to the principle, and to notice generally, at the cost of a little anticipation, the historical position which the doctrine holds in the science.

Neither of the two relations of the concept could be, or ever has been, altogether overlooked. But extension, which always predominates in thought, and thus modifies all natural forms of speech, long usurped in the logical field a place almost so broad as to leave no room for comprehension. So it was with Aristotle. So, likewise, was it with the schoolmen, who held that the *totum universale*, the whole of extension, is that with which only logic has directly to do; and that the science cannot look further away from it than for seeking marks (*notæ*) by which the mutual relations of universal wholes and parts may be determined. Thus comprehension lay in the dark.

"The distinction," says Hamilton (*Discussions*, p. 641*), "as limited to the doctrine of single notions, was first signalized by the Port-Royal logicians, under the names of extension and comprehension. Leibnitz and his followers preferred the more antithetic titles of extension and intension (though intension be here somewhat deflected from its proper meaning, that of degree); and the *quantitas ambitus* and *quantitas complexus* have, among sundry other synonyms, been employed in modern times—not exclusively, for Aristotle uses *τὸ πρὸς ἕκαστον* and *τὸ πρὸς ὅλον*. The best expression, I think, for the distinction, is breadth (*Πλάτος, latitudo*), and depth (*Βάθος, profunditas*)." (See the Port-Royal *Logique*, part i., chap. vi.) Both the correlation and its law (of the inverse ratio), speedily became familiar to all logical students. "It is," says Reid, "an axiom in logic, that the more extensive any general term is, it is the less comprehensive; and, on the contrary, the more comprehensive, the less extensive." (Hamilton's *Reid*, p. 390.) But in our climate the doctrine bore no fruit.

In the *Logic* of Kant the correlation is alleged, and the law of the inverse ratio stated: the first steps also are taken towards those applications of the principle which speedily followed. Since then, it has been trite doctrine in the German schools, that a definition is a predication making distinct the comprehension of a concept; that a division is a predication making distinct the extension: and, while the German logicians have not all generalized with equal clearness the law of the inverse ratio, their success in expicating the theory of both processes has been proportional to the clearness with which they have apprehended the principle. Compare, for

any attribute possessed by all organized beings. But, as a mark either of the term "animal," or of the term "vegetable," we may assign "organization," the attribute signified by the term "organized being;" and, as a mark of "man," or any of its co-ordinates, we may assign "animal life" as a mark in the first degree, and "organization" as a mark in the second. All animals may be marked as organized beings; all men may be marked as animals and organized beings.

¹ The terms of the example in the last section would have stood thus when ordained in extension from above:—

1. Organized being; 2. Animal + vegetable; 3. Man + beast + bird + fish + reptile + insect.

The same terms ordained from above in comprehension would stand thus:—

1. Man + beast + bird + fish + reptile + insect; 2. Animal + vegetable; 3. Organized being.

When explicit ordination is required as an aid for analysis, it is safest and easiest to make it in the descending order of Extension. The counter-relations are discoverable at a glance.

Doctrine of instance, Twisten with Fries. At this point, however, the German logicians have come to a stand. With a solitary exception, none of them, so far as we know, has suspected the possibility of bringing the double relation of the concept to bear on the syllogism. The one exception is Beneke; who, however, after having seemingly grasped the principle very firmly, lets it slip out of his hands before it has yielded any generalized doctrine. (See his *Lehrbuch der Logik*, 1832, chap. viii., §§ 170, 171, 182.) It should be added that Beneke saw, very clearly, how the distribution of the predicate in affirmative propositions is necessary for the consistent development of the relation of comprehension. (See his sect. 182, foot of page 124.)

This one hesitating anticipation required in fairness to be noticed. But it leaves untouched the essential originality, as well as the whole value, of Sir William Hamilton's masterly application of the counter-wholes to the elucidation and firmer grounding of the theory of the syllogism. This deepest section of his logical system seems to have been as yet little studied. But it may not be

presumptuous to hint a belief, that his formal doctrine of the thorough-going quantification of the predicate will be found to have its chief value, and perhaps its only practical applicability, in its efficiency as an instrument for evolving the syllogistic bearings of the comprehension and extension of concepts. Some of these bearings it will be attempted by and by to explain.

Yet, further, it has to be remarked that, contemporaneously with Hamilton, two other great logicians have seized the same thought; both of them, however, grasping it from the negative side, and not working it out to any positive formal results. Professor Trendelenburg lays it down in the broadest terms, that the law of the syllogism can be understood only through the mutual relation of extension and comprehension. (*Logische Untersuchungen*, 1840, ii., pp. 232-250, § 16.) Mr Mill has a much less firm hold of the idea, mainly by reason of his avoidance of the formal point of view; but in the counter-relation of the two wholes lies the clue to the distinction which he has used so skilfully in working out his own system—that between the denotation and the connotation of terms.

PART II.—THE DOCTRINE OF PROPOSITIONS.

CHAPTER I.

The Forms of Categorical Predication.

The character of categorical predication.

34. The only kind of proposition which is the direct expression of a simple judgment, is that which is technically called the *Categorical*. From those other kinds which are usually compared with it by logicians, it may be distinguished with sufficient exactness, when it is described as being an assertion or predication, affirmative or negative, not limited either by a condition or by an alternative.¹

All categorical propositions are formally resolvable, though not all with equal ease, into three parts or factors:—The *Subject*, which is a name for that which is spoken of; the *Predicate*, which is a name for that which is said of that which is spoken of; the *Copula*, a verb, in which the assertion is expressed, and which likewise qualifies the assertion as an affirmation or a denial. The subject and predicate are called the *Terms* of the proposition.

In many common forms of speech, the copula is mixed up with the predicate: but they may always be separated; and for exact logical analysis they must be so. The pure copula is always "is" or "is not," "are" or "are not," words which, when discharging this function, do not import existence, nor even any mode of time, but merely the fact that the things thought as denoted severally by the subject and by the predicate, are thought in relation to each other.²

Propositions qualitatively resolvable into assertions of identity or difference.

35. The *Quality* of a proposition is the character of the predication it contains. As being the expression of a judgment, predication can have only the one or the other of two characters, and cannot have neither. It must be

¹ "X is Y" is a categorical proposition. Examples of the other kinds are these:—Of the Hypothetical, "If X is Y, it is Z;" of the Disjunctive, "X is either Y or Z."

² The assertion, "The world—is," passes readily into the explicit form, "The world—is—something that exists." Many other resolutions are equally easy. "John thinks," becomes "John—is—a person thinking." The first in each of these pairs of propositions would have been called, by the old logicians, a *propositio secundi adjecti* (or *adjacentis*), as having but one factor expressly adjoined to the subject; the latter would be a *propositio tertii adjecti* (or *adjacentis*), as having a second factor also expressed.

The infinitive mood is a substantive, and is most easily useable in its gerundive form; and cases where it is one of the terms are those that oftenest present the predicate before the subject. "It is pleasant to know = All knowing is a thing pleasant." The propositions which the Germans have called existential, expressible by impersonal verbs (as "it thunders, it rains"), may always be regarded as expressions of an incomplete cognition, of a thought which we either cannot analyse or have not taken the trouble to attempt analysing.

either Affirmative or Negative. The copula, which expresses the act of predication, must either want, or have, the negative sign "not."

The question of quality emerges in regard to every proposition. It is the primary question, and also the most important of all.

The doctrine to be kept steadily in view is that which has already been laid down, and in part illustrated. In the data of every proposition, there is an hypothetical presupposition of duality: two ideas are given, whose designative terms are available as subject and predicate. The proposition intimates whether, in respect of the relation under which the objects are thought, the duality can or cannot be reduced to unity. The terms having been compared, the proposition expresses the determination of the thinker on this question: whether the object or objects denoted by the subject be identical or non-identical with the object or objects denoted by the predicate. An affirmative proposition predicates the identity of subject and predicate; it does so in all circumstances. The objects are asserted to be the same objects; although, when regarded from one point of view, they bear the name given them in the subject, and, from another point of view, the name (if it be a different name) given them in the predicate. So a negative proposition predicates in all circumstances non-identity or difference; it asserts that, whatever may be the names, or whatever the points of view from which the objects are regarded, the one object, or group of objects, is a different object or group from the other.

The question of identity or difference is the main question as to all objects compared in judgment; as to certain kinds of objects it is the only question.

36. When both subject and predicate are singular terms, Predication the quality of the proposition is the only point to be considered. Especially, there can be no question as to the quantity of the terms, each of which must signify an individual object, and cannot admit any limitation to its meaning. The proposition is a pure predication of identity or non-identity. Of the individual designated by the subject there may be affirmed, as predicate, any term which is merely another name for the same individual. Of that individual there must be denied, as predicate, any and every term which is a name for any other individual.

Cases of either sort arise too infrequently, and, when they do arise, are too easily disposed of, to require special rules.

37. The question of *Quantity* arises when common terms enter into propositions, as subject, or as predicate, or as both. Common terms being capable of signifying either

The quantity of common terms.

Doctrine of all the objects of a class or less-than-all of them, the question of quantity relates to the terms. Are they distributed or undistributed?

propositions.

The answer to this question as to the terms, serves only to guard and limit the affirmation or negation made by the copula. Rigidly and rightly considered, the determination of the quantity of a term, whether through its known meaning, or through interpretation of its sign, is nothing more than a method of protection against that ambiguity, which besets common terms on account of their capability of denoting either all or less-than-all. That which is properly a term in a proposition (whether subject or predicate), is not the common term in its capability of quantitative signification, but the common term as definitely interpreted to mean all or some.

This interpretation being gained, we proceed, when both terms are common, to decide whether the objects denoted by our subject (all, or some, of the objects constituting a certain class), are, or are not, the very same objects denoted by our predicate (all, or some, of the objects constituting a certain other class).

In a word, the determination of the quantity of the terms in a proposition, is nothing else or more than a step of preparation, in cases requiring it, for the determination between identity and non-identity, and for the consequent choice between affirmation and negation.¹

The four received forms of predication through common terms.

38. In regard to quantity, the received logical doctrine and nomenclature may be set down as follows:—

Propositions whose subjects are common terms, are said to have quantity, that is, variable quantity. A proposition is said to be Universal in respect of quantity, when its subject is distributed; it is called Particular when its subject is undistributed. The quantitative sign of the subject, "all," "any," or "some," if not given, is to be supplied. A proposition whose subject is a singular term cannot receive a sign, but must be treated as a universal.

It is admitted, by all logicians, that the predicate, when it is a common term, must, like the subject, have its quantity positively determined: it must, in every proposition, be either distributed or undistributed. Ordinary language, however, does not indicate the quantity of the predicate by any prefixed signs; and, in the received logical systems, no sign is supplied. It is held that the necessity for one is superseded by a fixed rule of interpretation. The quantity of the predicate, we are told, is fixed by the quality of the proposition, without any regard to its quantity: the predicate is distributed in all negative propositions, whether universal or particular; it is undistributed in all affirmatives. The reasons assigned for the rule are these.—A negative proposition cannot but distribute the predicate; for when, of anything whatever denoted by the subject, we deny the class denoted by the predicate, we deny that the subject is to be found anywhere in the predicate-class, or makes any

part of it; or we affirm, in effect, that the subject is excluded from the whole of the predicate. On the other hand, it is allowed, that an affirmative proposition either may or may not distribute the predicate. When, of anything whatever denoted by the subject, we affirm the class denoted by the predicate, we may mean, either that the subject constitutes the whole class, or only that the subject is contained in the class, or is a part of it. In the first case the predicate is distributed; in the second it is not so. But, it is alleged, the latter case of the two is the only one with which logic can deal. The narrowest meaning which an affirmative can bear, is the assertion that the subject is a part of the predicate; so much, therefore, may always be safely assumed. If the signification of the proposition really does embrace the wider alternative, the fact is discoverable only by means lying beyond the sphere of logic, a purely formal science, which possesses no machinery for interpreting the terms, or for otherwise working on the matter of propositions.¹

Doctrine of propositions.

Accordingly, the common scheme of propositions, and the scheme of inferences founded on it, are confined to forms of predication from which affirmatives that distribute the predicate, and negatives that do not, are alike excluded.

This exclusion being made, the possible Forms of Predication, through common terms, are necessarily no more than four. For the sake of brevity in naming, those four kinds of propositions are noted by the first four vowels. The letter A denotes a universal affirmative (subject distributed, predicate undistributed); I denotes a particular affirmative (subject undistributed, predicate undistributed); E denotes a universal negative (subject distributed, predicate distributed); O denotes a particular negative (subject undistributed, predicate distributed).

The designation of propositions as universal or particular, in respect of the quantity of the subject, cannot be questioned. The four forms marked by the vowels are likewise unchallengeable.

But it has lately been questioned whether logic is either bound, or so much as entitled, to exclude all forms of predication besides the A, I, E, O. Both of the exclusions have been condemned; not only the exclusion of affirmatives which distribute the predicate, but even the exclusion of negatives whose predicate is undistributed. These points, therefore, must be more closely examined.

It has likewise been proposed, that, in the preparation of propositions for logical treatment, the signs of quantity be prefixed to predicate as well as to subject. This express signature of the quantity of the predicate is fruitful in results, to an extent which would scarcely be anticipated from an expedient so simple and so purely formal. It will be adopted in our further progress, with all examples where exact analysis is aimed at.²

¹ "All metals are minerals = All metals—are—some minerals." The terms might be held to be the two class-names "metals," "minerals;" and in this view the proposition might be described as being an assertion of partial identity between the two classes. "The whole class metals—is identical with—some part or other of the class minerals." But such an analysis is apt to cause indistinctness of thought, and that because it does not go far enough. Our terms are properly not the class-names taken without fixing of quantity, but these names as quantitatively determined by the signs; in other words, our terms here are names positively used to designate all the objects of the first class—some or other of the objects of the second. Thus regarded, the proposition is seen to be an assertion of total identity, between the objects denoted by the first name and the objects denoted by the second. "The objects which, in respect of certain properties possessed by them, and not possessed by any other objects, I call 'all metals'—are (or are the same objects with)—the objects which, in respect of certain properties possessed by them, but possessed also by other objects, I call 'some minerals.'"

² It is not to be wondered at, that the peremptory refusal to look at the meaning of the terms should be adhered to by the German logicians; among so many of whom, since the time of Kant, the purely formal or *a priori* character of logical science has been a cardinal article of faith. Yet, in not a few of the German systems of logic, the doctrine of definitions and divisions (which are admitted to be universal affirmatives distributing the predicate), is very thoroughly expounded, the case being treated as exceptional. It might surprise us more that the refusal should be insisted on so generally among English logicians; since by them the exclusion of matter from logical scrutiny has, though usually asserted as a rule, been scarcely ever traced up to principles, while it has been practically departed from in many other points of doctrine.

The express signature of predicates is a proposal of Sir William Hamilton's. Lambert, indeed (*Neues Organon*, 1764, p. 116), had invented a scheme of logical notation, in which effect was given to the quantity of every term; and Ploucquet (1761) had suggested the prefixing of the quantitative sign to the predicate in all assertions expressed for logical use. (See Fries, *System der Logik*, ed. 1837, p. 103.) But the signature of the predicate was still, by all later logicians, unadopted. Its effects are surprising. Doctrines already admitted and proved are, by means of it, made more easily expli-

Doctrines of proposi-
tions.
The eight possible forms of predication through common terms.

39. Every proposition has two alternatives of quality. Every common term has two alternatives of quantity; and the terms of every proposition are two; consequently, if quality is to have no effect, every proposition has four alternatives of quantity. If, then, we look merely to the combinations of number, the possible forms of predication must be eight.

The following formulæ exemplify these eight kinds of propositions, note the quantities, and explicate the asserted identities and differences:—

1. A. All X's are some Y's = All the X's—are identical with—some or other of the Y's.
2. I. Some X's are some Y's = Some or other of the X's—are identical with—some or other of the Y's.
3. A². All X's are all Y's = All the X's—are identical with—all the Y's.
4. I². Some X's are all Y's = Some or other of the X's—are identical with—all the Y's.
5. E. Any X's are not any Y's = All the X's—are non-identical with—all the Y's.
6. O. Some X's are not any Y's = Some or other of the X's—are non-identical with—all the Y's.
7. $\frac{1}{2}$ E. Any X's are not some Y's = All the X's—are non-identical with—some or other of the Y's.
8. $\frac{1}{2}$ O. Some X's are not some Y's = Some or other of the X's—are non-identical with—some or other of the Y's.¹

To the received scheme of predication, there would thus be added four forms, two affirmatives and two negatives. All of these express possible forms of thought; and, accordingly, admission has been demanded for all of them, as necessary for the completion of that theory of thought which logic undertakes to set forth. Admission, again, has been demanded for the affirmatives, but refused to the negatives. The grounds of both claims require examination.²

cable; other doctrines become traceable to principles which had hitherto been overlooked; and there are brought to the surface new doctrines, which had been unsuspected because the quantity of the predicate, through its want of express marks, had not been attended to unless when it bore on questions already raised.

¹ Examples in Significant Terms.

1. A. All men are imperfect = All men—are—some beings imperfect.
2. I. Some men are happy = Some men—are—some beings happy.
3. A². All men are responsible animals = All men—are—all animals responsible.
4. I². Some men are logicians = Some men—are—all logicians.
5. E. No men are stones = Any men—are not—any stones.
6. O. Some men are not wise = Some men—are not—any persons wise.
7. $\frac{1}{2}$ E. No men are some Z's = Any men—are not—some (or other) of the Z's.
8. $\frac{1}{2}$ O. Some men are not some Z's = Some men (or other)—are not—some (or other) of the Z's.

² The A² at least might have been expected to be acknowledged by some of the German logicians, who perceived so exactly the character of definitions and divisions, and were compelled to admit that these are instances of that form. But they content themselves with repeating the old declaration, that the distribution of the predicate in affirmatives, when it does occur, is "accidental"—"not cognizable from the position at which logic takes its stand." If the view be correct which will be stated in the text, it is more to be regretted that they had not given reception to I², especially since one of them has been quite aware that it is the full and only adequate converse of A. The observation is Beneke's, in a passage of his *Lehrbuch*, p. 182, which has already been referred to (note to section 33.) The only formal recognition of the distributed predicate in affirmatives, which we have observed among the German logicians, is that of Hoffbauer, who not only recognizes reciprocal propositions (A²), but lays down rules for syllogisms having both premises of that character. (*Anfangsgründe der Logik*, ed. 1810, pp. 97, 100, 185.)

In Mr George Bentham's *Outline of a New System of Logic* (1827, p. 133), all the eight possible forms are correctly set forth. But the writer instantly loses hold of the clue he had grasped: indeed, he goes so far astray as to maintain, that in negatives it is a matter of indifference whether the predicate be distributed or not.

40. More than one characteristic feature of predication may be thrown into light, if we consider every proposition as being, actually or possibly, the answer to a question. A problem is propounded in thought: a judgment is the solu-

Doctrines of proposi-
tions.

The six available forms of predication through common terms.

He ends by returning to the A, E, I, O. In Mr Solly's *Syllabus of Logic* (1839, p. 47), the eight forms are stated as arithmetically possible; and their character is shown by the prefixing of signs to the predicate. But the four added forms are at once thrown aside, as never introduced in practice. The claim for all the eight is made by Sir William Hamilton; and all of them are worked by him into his scheme of syllogisms. The admission of both quantities of predicate, with both qualities of copula, makes up his "Thorough-going quantification of the predicate." (See his *Discussions*, Appendix ii.; and Baynes' *New Analytic*.) Mr Thomson (*Laws of Thought*, 1842, 1849, 1854) rejects the additional negatives, but incorporates the additional affirmatives into his syllogistic tables. They are his U and Y. The symbols here proposed for those two affirmatives (A² and I²) seem to have some advantages. While easily pronounceable, they intimate a relation of the two forms to the received A and I; and the character of this relation is faintly hinted at, when the added forms are symbolized as higher powers of the old ones. The propriety of the two negative symbols, $\frac{1}{2}$ E and $\frac{1}{2}$ O, is a matter of very little consequence: they are to be thrown aside; and it is enough that we have brief modes of naming them in discussing the reasons for and against their reception.

In reference to Sir W. Hamilton's system, it may be well to remark, that his invaluable suggestion of always marking expressly the quantity of the predicate is one thing, that his proposed extension of the propositional forms by "thorough-going quantification" is another. In Mr Baynes' Appendix are interesting quotations from old logicians, who have contemplated the distribution of the predicate in affirmatives, and signified it by the universal sign. Instances, too, are cited, in which the bearing of this distribution on the syllogism is hinted at.

Perhaps the following passages are more decided in the application of the distributed predicate, than any of Mr Baynes' quotations. They carry us from the fourteenth century to the sixteenth; from an Englishman, the "prince of nominalists," one of the greatest of the earlier schoolmen, to a Scotsman, who has been called the last of the schoolmen, and was far from being the least subtle of the band.

In Occam's *Summa Totius Logice*, one chapter (lib. iii., cap. 13) is described in its title as showing "in what cases we may syllogize from two affirmative premises in the second figure." Two cases are described. The first is that in which the middle term is a singular. It is the second case that interests us here. "Secundus casus est, quando medius terminus sumitur cum signo universalis. Tunc semper contingit inferre conclusionem affirmativam, in qua major extremitas predicatur de minori. Bene enim sequitur: 'Omnis homo est omne risibile; Socrates est omne risibile; ergo Socrates est homo.'" "Iste autem discursus probatur per hoc: quod semper talis propositio major convertitur in unam universalem affirmativam; qua conversione facta, patet quod discursus est in prima figura, regulatus per dici de omni." The A² is here given twice. Only it is noticeable that the proposition is not considered, as it might have been, to be convertible into another A² (which would have yielded an unrecognized mood in the first figure); and hence it is that the predicate of the conclusion is undistributed. In the next paragraph the I² is, though not exemplified, unequivocally described; and it is correctly alleged to justify syllogisms with two particular premises. "Et est sciendum, quod in duobus predictis casibus non solum contingit arguere ex universalibus affirmativis; sed etiam contingit arguere ex omnibus affirmativis particularibus; et eodem modo probantur tales syllogismi ex particularibus sicut ex universalibus. . . . Et tenet talis discursus, non gratia materiæ, sed gratia formæ: quia, in omni materia, observato quod medius terminus sit terminus discretus, vel sumptus cum signo universalis in majori, discursus est bonus."

The other authority is Joannes Major (John Mair), now remembered only as an historian; who, besides teaching in Paris, was a regent, and afterwards provost, of the College of St Salvator in the Scottish University of Saint Andrews. His *Introduitorium in Aristotelicam Dialecticam*, printed at Paris in 1627, while it shows close study of Occam's doctrines, is prominently marked by the writer's characteristic independence of thought. He makes very frequent use of the distributed predicate in affirmatives. The following points are especially noticeable.

1. Instead of rejecting the form, he merely says it is uncommon: "affirmativæ prædicatum raro distribuitur." (*fol. cxlviii., col. d.*)
2. In expounding the reciprocity of deduction and induction ("deccensus" and "ascensus"), he insists on the universality of the predicate, in a collective acceptance of the sign, as a fixed datum;

Doctrine of
proposi-
tions.

tion. We ask, what is B? We answer, B is X. That which is denoted by the subject is always the *datum*; something expressible as a predicate is the *quesitum*. The subject may be called the antecedent, the predicate the consequent; and the hypothetical or conditional form of stating a proposition places the terms expressly in that relation:—"If B is B, it is X."

We have seen, already, that concepts are the only consequents yielding any positive knowledge worth having; that common terms are the only predicates yielding affirmative propositions worth expressing. Among common terms, then, our predicates are sought. We desire to affirm of our subject the name of a class. A known class will yield a predicate, if we can think that our subject makes even a part of it; and, if this is all we can think, our predicate will be undistributed. If our subject is a singular term, our affirmation cannot embrace the predicate more widely. The individual denoted by it can be only one or another of the objects which constitute the class indicated in our predicate.

But, if our subject is a common term, the objects it denotes may be either some, or all, of the things constituting a class denoted by another common term; or, again, they may not be any of the things constituting that class. Thus there arise three cases, all of them possible, actual, and more or less frequent.

First, We may be entitled to think of the objects denoted by the subject as being only some, not more, or to think of them as being certainly some, though we do not know whether they are or are not all, of the things denotable by the predicate. Either state of our knowledge will yield an affirmative predication, having the character of the affirmatives in the received list. It will be an affirmative with an undistributed predicate, an A or an I, as the subject is distributed or undistributed. Such propositions may conveniently be called Propositions of Inclusion: they assert only that the subject is included in the class which yields the predicate.

Propositions of inclusion make up a very large majority of the affirmatives that actually occur; and perhaps they are, without exception, the only affirmatives which we ever use exhaustively as data, unless when, as in scientific discussions, we reason from definitions.

Secondly, however, there do occur also affirmatives which may be called Propositions of Constitution. In these, the things denoted by the subject are thought of as being all the things denotable by the predicate: they are asserted to constitute the class of which the predicate is a name. The propositions are affirmatives with distributed predicates.

"constantia est hæc propositio: isti pomæ sunt omnes pomæ. . . . istæ arbores sunt omnes arbores." (fol. cxliii., a, b.) 3. He indorses Occam's verdict on the second figure, lays down a principle for protection against resulting fallacies, and assigns a practical reason for the limitations assumed in the received syllogistic rules. "Dicces forte, hæc consequentia est bona: 'omnis homo omne animal est; et omnis asinus est animal: ergo omnis asinus est homo.' . . . Respondetur in uno verbo. Ubi a mendis, ratione quorum regulæ sunt traditæ, præcavetur, majore particulari aut utraque præmissarum affirmativa, discursus in hac figura, sicut in aliis, est formalis. . . . Primi regularum traditores de propositionibus communiter consuetis loquuti sunt; hoc est, de affirmativa cum prædicato distribubili non distributo, et de negativa cum prædicato distributo." (fol. civi., c.) 4. Afterwards he deals similarly with the third figure. (fol. clviii. b.)

It may be noted, also, that both of those dialecticians treat, and Occam very diffusely, a current scholastic distinction which appears in one of Mr Baynes' quotations. The "suppositio" of terms in propositions (that is, their objective reference), was said to be of two kinds, "determinata" and "confusa;" the latter, again, being either "confusa tantum" or "confusa et distributa." The complexity and vacillation of the old rules of "suppositio" seem to have sprung from two sources: an indistinct apprehension of the effect which non-distribution of the predicate has on affirmation; and a frequent attempt to identify singular terms with common terms undistributed.

Universal propositions of this type, the A² of our formulæ, Doctrine of are exemplified by definitions, and also by logical divisions. propositions. Particular propositions of the kind, the I² of our formulæ—particular propositions which are interpreted imperfectly unless the predicate is held to be distributed—occur more frequently than we are apt to suppose. We shall encounter them, by and by, as being really the only complete and direct converses of the A of the received scheme.

Propositions really treatable as A² and I², have been currently handled by logicians, and are very frequent in ordinary thought. They are technically spoken of as exclusive propositions: "Men are the only responsible animals." They are usually treated as compound. The example is resolved into these two assertions:—1. "Men are responsible animals;" that is, they are some at least of the class; the question, whether they are the whole class, being supposed to be in the first instance undecided: 2. "Creatures which are not responsible animals are not men." But, if we allow distribution of the predicate, the proposition is interpretable as expressing one simple judgment: "All men—are—all responsible animals."¹

When, therefore, the purpose is to predicate a relation between the subject and a class, there are data for affirmation, first, when we are able to assert inclusion; secondly, when we are able to assert constitution.

Thirdly, The same purpose being entertained, we have data for negation, when we are able to assert exclusion. A Proposition of Exclusion is one which asserts that the things denoted by the subject are excluded from the class denoted by the predicate; that, in other words, they do not make any part of that class, or that they are non-identical with all the things which that class contains. Evidently such propositions have the predicate distributed. They are the E and O of the received scheme.

They are not only of continual occurrence, but widely useful. In every kind of inquiry, we are able to deny a great deal more than we are able to affirm; and a denial which entitles us to set aside a whole class of things as being not the things we are interested in, is often one of the most valuable of all steps towards our learning what the things we investigate positively are.

41. When we desire to explicate our implied knowledge The two by referring our objects to a class, the three judgments ex- non-avail- pressible by the three kinds of propositions which have now- able forms been explained, appear to be all the judgments that can tion of predica- either constitute positive knowledge, or be steps leading through tion towards it. We must assert either inclusion, by A or I; common or constitution, by A² or I²; or total exclusion, by E or O. terms.

Propositions having the character of our seventh and eighth formulæ, $\frac{1}{2}$ E and $\frac{1}{2}$ O, do not seem to occur at all. Can there be detected, in actual thought, any examples of

¹ For the only uses to which it is here intended to apply either A² or I², it is scarcely necessary to raise a question, which, however, would require consideration if these forms were to be worked up into additional syllogistic moods. The "all" of the received A is distributive. Can it be so in these added forms? or, is it necessarily collective? Sir William Hamilton declares incidentally that the totality may be thought either way. "We can say, as we think, affirmatively, 'All triangles are all trilaterals.' This collectively, 'the whole (or class) triangle is the whole (or class) trilateral.' This distributively, 'every (or each several) triangle is every (or each several) trilateral.'" (*Discussions*, Appendix ii., p. 627.) It is difficult to see one's way clearly through the distributive interpretation. Perhaps it may be justified thus:—Let the given proposition be, "All X's are all Y's." Collectively taken, the assertion is, that the aggregate of the X's is the same with the aggregate of the Y's; that is, the whole class X is the same with the whole class Y. Distributively taken, it may be regarded through the names:—each of the things which, when viewed from a certain point, we call X, would, when viewed from another point, be each of the things we call Y.

Doctrine of negatives, whose predicate, when its true function is brought to light, proves to be undistributed? One should not expect to find such. They could not serve any conceivable use, either as data for inference, or as conclusions to be inferred. We know, or are on the way towards knowing, when we are able to assert, either that our subject is *in* a class, or that it *constitutes* a class, or that it is *out of* a class. But the propositions in question do not assert any of these three things. They assert, not knowledge, but doubt: and the doubt which they do assert does not cover any the tiniest germ of knowledge, in regard to the objects from which we started,—those which are denoted by the subject, and which we wish to determine, positively or negatively, through the predicate.

In the formation of an opinion in regard to them, the indefinite character of logical particularity must be kept sternly in view. If the logical "some" were definite, those negatives would be virtually the received E and O. They would assert the exclusion of the subject, not, indeed, from the whole class denoted by the term which is formally the predicate, but from a certain fixed part of that class, which part would really be a sub-class, and ought to yield a name which would be the true predicate. But the logical "some" is, and must be, indefinite; and it is on this footing that the propositions have been placed, when they are asserted to be forms of thought, the analysis of which ought to have a place in logic.

Whenever the subject of a proposition is indeterminate in quantity, because particular (as "some or other of the X's"), we have a very narrow field both for predication and for inference. The defect, however, is often unavoidable. The subject is our datum; it is the name of that which is given us to be judged of. But, be our subject quantitatively determinate or not ("all" or "some"), we seek for it a predicate which shall force us to assert, on pain of self-contradiction, the identity or non-identity of the objects denoted by the subject with objects denoted by the predicate. A predicate quantitatively undetermined by being particular, will yield an affirmation, A or I. In judging that "The X's (all or some) are some or other of the Y's," we have found for our subject a positive place in the field of our knowledge,—a place somewhere among the objects we call Y's: we have identified our subject with some or other of the Y's; and we are put on the track towards discovering its place still more exactly, through subsequent scrutiny of the Y's. But, if we must judge negatively, an undistributed predicate does not fix the place of our subject anywhere, either among or not among the objects we already know. The assertion that the X's (all or some) are not some or other of the Y's, does not contradict either the assertion that our given X's are things different from all the Y's, or the assertion that they are identical with some things or other lying in those parts of the sphere of the Y's, which our given predicate must have left unfilled. In a word, our proposition is nothing better than an involved expression for a barren alternative. Our X's, we learn, either are Y's, or they are not Y's; which is no more than what we know to be true, by the axiom of determination, in regard to any term whatever in its relation to any other.

It is well, then, that propositions having this character should be recognized as expressing possible forms of thought; it is well that we should know every garb, in which even doubt and ignorance may clothe themselves. But there does not appear to be any sufficient reason for complicating the rules either of inference or of predication, by extending them to forms which yield no real explanation of any given thought. Certainly such a proposition is never given to be inferred from. If such a proposition is the only one that can be inferred from an-

other, the fact is a significant testimony to the poverty of the datum.¹

42. Our scrutiny of the eight possible forms of predication leads to this result.

The four forms of the schools retain their place without challenge from any quarter; and doctrines bearing on them must always constitute the main part in the logical theory both of predication and of inference. Our chief duty must be the development of them: of the two affirmatives, A and I, propositions of inclusion; of the two negatives, E and O, propositions of exclusion.

But there do not seem to be good reasons for absolutely refusing a place in the logical system to propositions of constitution—the affirmatives which have been marked as A² and I². When an affirmation in which the predicate is distributed occurs in actual reasoning, we cannot apply to it rules which suppose its predicate to be undistributed, without the risk of either contracting unduly the limits of inference from it, or admitting wrongly the validity of inferences through which it may have been gained.

The latter of the dangers is probably the more imminent of the two. The increase in the power of inference through distribution of the predicate proves, on narrow inspection, to be by no means so large as we might expect it to be. Besides this, neither of the added forms can actually occur in reasoning, as data or premises, unless in the way of exception, and in circumstances making it easy for any one familiar with logical principles to apply the necessary correction to the conclusion. At all events, no attempt will here be made to work these forms, as premises, into the received scheme of the categorical syllogism.

But they should and will be used, as materials of great value for fortifying some weak points of the current logical system. Definitions and divisions cannot be thoroughly understood, unless through the A². Disjunctive propositions rest wholly on it. The I², again, is imperatively required for giving consistency and completeness to the theory of conversion; and through this process it has bearings on the syllogism.

If the current objection is urged, that the mere form of an affirmative does not enable us to know whether the predicate actually is distributed or not, the answer is not far to seek. It is true that we are not, *qua* logicians, able to interpret our terms, far less to decide the question of truth or falsehood for any one proposition considered by itself. But, even when one proposition only is given, we are entitled, before we undertake dealing with it, to demand, from without, all the information required for enabling us to apply logical laws.

The information we do demand is not extensive. It is wholly embraced in the two postulates laid down in our preliminary inquiries. We ask to be informed, in regard to every term given, whether it is to be understood as a singular or as a common term. If it has the latter meaning, we ask to be informed whether it is distributed or undistributed. For negatives, the information comes of itself. For affirmatives, we are entitled to summon it. If such a proposition is really either an A² or an I², we have a right to require warning of the fact. If, on the other hand, we evolve either form for ourselves, we are equally well entitled to make the peculiarity clear, by prefixing of the quantitative sign to the predicate.

43. All predication is reducible into categorical forms; and, as it has already been alleged, every categorical predication may be dissected into the three constitutive factors of the proposition,—Subject, Predicate, and Copula. A

The interpretation of propositions.

Doctrine of propositions. Doctrine of propositions.

proposition is not naturalized in our realm,—it has neither acquired logical privileges, nor become fully amenable to logical laws,—until it has submitted itself to both steps of this transformation, and has completed its legitimation by obedience to the postulates.

Such a process of preparation, while it lies beyond the function of pure logic, pre-supposes, likewise, interpretation of the terms; a duty which is still more distant from ours, and which can seldom be performed efficiently without a scrutiny, utterly extra-logical, of the truth or falsehood of the given assertions.

But, in a system of applied logic, an introductory section might, fitly and advantageously, be employed in such an analysis of the ordinary forms of predication, as should exhibit their relations to the logical forms, and found rules or aids both for interpretation and for transformation. Even for the design here entertained, some such assistance may advisably be offered; although it cannot, and need not, embrace any modes of expression except a few of those which are likely to prove most troublesome in elementary logical study. Assertions made for purposes other than logical, do seldom wear a shape fitting them for logical use; and we may warrantably turn aside for a little, to examine some of the most common varieties of predication, and to discover, if we can, in what way, and how far, they may be made available as elements of inference. A few hints to this effect are thrown into the second of the notes appended to the present chapter.

NOTE I.

Sir W. Hamilton's Partial Negatives.

Our seventh and eighth propositions, marked as $\frac{1}{2}E$ and $\frac{1}{2}O$, are the new and peculiar forms of predication in Sir William Hamilton's system: they are his Partial Negatives, Toto-partial and Parti-partial. Forms so authoritatively recommended cannot be so much as questioned, without a painful distrust in one's own judgment; nor can they be set aside but with reluctance and hesitation, even if the ground of dissent should seem to be very firm. It is right that the argument should be stated more precisely than in the text; although the points cannot be brought out without assuming doctrines which have to be explained afterwards.

1. It is alleged, in the text, that the propositions $\frac{1}{2}E$ and $\frac{1}{2}O$ leave open the universally prevailing alternative of the excluded middle: "Our given X's either are or are not Y's." The quantity of the subject being here indifferent, let the universal proposition $\frac{1}{2}E$ be taken for illustration: "The X's (any X's) are not some or other of the Y's." (1.) This is not inconsistent with the assertion (A) that "All the X's are some or other of the Y's:" for, though the X's are not some or other undetermined Y's, they may be some other Y's also undetermined. I may say that "Men are not some or other of the objects we call imperfect beings," without contradicting the true assertion, that "Men are some or other of those beings." I may say that men are not to be found in some undetermined part of the class of imperfect beings, although I know that men are to be found in some other undetermined part of the class. (2.) The proposition is not inconsistent with the assertion (E) that "None of the X's are any of the Y's:" indeed, the assertion that "The X's are not some undetermined Y's," is implied in the assertion that "The X's are not any Y's:" it is a clumsy subalternate. If I choose to assert, "Men are not some or other of the objects we call stones," I assert a part of the wider truth, that "Men are not any of those objects." The assertion that men are not in some undetermined part of the class, is covered by the assertion that men are not in any part of the class. (3.) Accordingly, our proposition is consistent both with the proposition of inclusion, "All the X's are Y's," and with the proposition of exclusion, "The X's (any) are not Y's." It leaves untouched the disjunctive proposition, "The X's are either Y's or not Y's." This proposition collects the whole of our positive knowledge of the X's; and that knowledge is really no knowledge at all. Anything whatever must be either Y or not Y; so therefore, of course, must our X's be. (4.) We may regard the proposition as a fact of naming. The question then is this: Is our predicate a name which may be given to the things for which our subject is another name? May the things which, looking at them in respect of certain of their attributes, we call X's, be also called

Y's, in respect of certain other attributes? The question cannot be answered. Our predicate Y may be a name, both for our X's and for other things; or it may not be a name for any of our X's.

2. It appears, then, that of the three kinds of propositions which have, in the text, been asserted to be the only ones available for the explication of implied knowledge, there are two towards which the propositions in question are indifferent. Such a proposition is consistent with a proposition of inclusion: it is consistent with a proposition of exclusion. Now these two are the only kinds of propositions taken account of in the received logical systems. Therefore, if a proposition were given in either of the two new forms, we could not, with the same subject and predicate discharging the same functions, evolve, for the application of the common rules, either an affirmative (A or I), or a negative (E or O).

3. It must be allowed, however, that our propositions do give us hold of a predication of one sort. They are inconsistent with our third kind of propositions, those of constitution. If it is true that our X's are not some or other of the Y's, it cannot be true that they are all the Y's: since the X's are different things from some Y's or other, they cannot be identical with all the Y's. If, then, we assert, in our new forms, that "The X's (any or some) are not some Y's," we cannot, without self-contradiction, assert that "The X's (all or some) are all the Y's." Therefore, $\frac{1}{2}E$ and $\frac{1}{2}O$ severally contradict our A² and I². If we are to gain an expression for the contradictory thus implied, and if we are still to adhere to our given subject as subject, we evolve such an assertion as this: "The X's (all or some) either are not Y's, or, if they are Y's, they are not the only Y's." We are still forced into the disjunctive proposition, if we are to express all that our relation implies. But the positive member of our alternative has now received a negative limitation; and in this limitation lies the only force of our proposition as an element of knowledge.

4. It has such a force. For there is extricable, from our newly-gained disjunctive, a proposition in a received form, which, while it leaves open the A and I like our datum, does also like it contradict categorically the A² or I². It is expressible so as to cover both of the challenged forms: "There are Y's which are not our X's = Some Y's or other—are not—our X's." (1.) If our given proposition was "Some X's are not some Y's," our evolved proposition is, "Some Y's are not some X's." This assertion fulfils the conditions above alleged; but, being a re-emergence of the challengeable form, it may be passed over. (2.) If our given proposition was, "The X's (any X's) are not some Y's," the evolved proposition is, "Some Y's are not any X's." This proposition calls for particular examination. In the first place, it is not inconsistent with the assertion that "All X's are some Y's" (A). It is true that "Some men are not (any) sages;" though it is also true that "All sages are (some) men." Secondly, it is not inconsistent with the assertion that "No X's are any Y's" (E): indeed, the assertion that "Some stones are not (any) men," might be worked out of the assertion that "No men are (any) stones." Further, it is plainly inconsistent with the assertion that "All the X's are all the Y's" (A²): and thus it is also inconsistent with the I². If there are any Y's besides the X's, we cannot say, consistently, that the X's, or some of them, comprehend all the Y's. Lastly, the proposition we have thus gained is in one of the received forms: it is an O, a particular negative with distributed predicate.

5. Our extricated proposition, then, is a proposition of exclusion, a workable assertion of non-identity. But mark how it stands relatively to the point from which we started. Our terms have exchanged functions. Our subject has become predicate; our predicate has become subject. Our given subject, that term which was proposed for determination, was "the X's;" we sought to determine that term negatively through the term "some Y's." We failed in the attempt: we have failed even now. What we have been able to do is, not to determine X through Y, but to determine Y through X. We have asserted, in our new proposition, nothing about X as subject: we have asserted something about Y, shelving X into the office of predicate. In short, when we endeavoured to use the proposition as given, we discovered that we had grasped it by the wrong handle: when thus treated it slipped away from us. We have next seized it from the opposite side; and now our hold is firm.

6. Technically described, our change of position has been this: we have Converted the given proposition. Our O fulfils all the logical conditions of a valid converse. We were unable to extricate from our datum, either by affirmation or by negation, any determination as to our subject through our predicate. But conversion has yielded us a negative determination of our predicate through our subject.

7. If, then, it were conceivable that there should be actually given a proposition in the seventh form, our only feasible method of procedure would be founded on the theory, that our datum is a product of perplexed and mistaken thought. In form denying the

Doctrine of propositions. predicate of the subject, but not really amounting to such a denial, it does really imply an assertion in which the subject is denied of the predicate. Any one who should think in such a form, must, we would assume, have mistaken the substance for the attribute; and contrariwise. We should have to evolve the positive thought, and make it distinct, by transposing the terms. If such an expedient is not proposed in the text, it is because it does not seem to be the fact, that confusion of thought ever does show itself in this out-of-the-way guise.

8. The strongest claim of the seventh form to admission into the syllogistic system, rests on this relation between the proposition and its converse. But the claim takes the case from the side opposite to that on which we have hitherto looked at it.

It is a received and unchallengeable logical doctrine, that, all negatives being held to distribute the predicate, the O of the common scheme does not admit conversion into any proposition of that scheme: (its conversion by contraposition is really a conversion, not of the O, but of an I inferred from it). In a just conversion, while the quality of the proposition must remain unchanged, the terms must be transposed as wholes, quantity included. Given, then, "Some X's—are not—any Y's" (O); the subject "Some X's" cannot do duty as predicate. The impossibility of directly converting O, cripples seriously our dealing with two of the syllogistic moods, Baroco and Bocardo.

If our seventh form be admitted, it gives instant relief. It yields a converse of O: "Any Y's—are not—some X's." All the four kinds of propositions are now convertible; and the two formidable syllogisms are lowered from their bad eminence.

9. The question is, what has been gained by this transformation of the O? Why, we have displaced an assertion expressing a pregnant, though narrow thought, and have erected in its place the expression of an empty shadow of thinking. We had received a negative determination of our limited subject; we have transformed it into a total want of determination of our more extensive predicate. We have been allowed to start from a judgment which, though the narrowest that is knowledge at all, is yet, within its small bounds, a knowledge precise and usable: we have wilfully thrown ourselves back into a position of pure doubt, a position from which we cannot rise unless by returning to the very point we had deserted.

10. The particular negative (O) of the received doctrine is the weakest of all possible judgments. The relation which it asserts is the narrowest that can yield any knowledge whatever: the amount of inference it allows is smaller than that given by any other proposition. One of the most telling proofs of its feebleness is the fact that, while it does deny something of the subject, it does not really either affirm or deny anything categorically of the predicate. The old logicians have recognised this fact, in pronouncing the O to be inconvertible: and, in the face of the temptation held out by a dazzling promise of increase in the forms of predication, the belief forces itself on us, that the old logicians were in the right.

11. One other query may be hazarded, bearing on that thorough extrication of the two wholes of the concept, the application of which to the theory of the syllogism is so admirable and original a feature in Sir W. Hamilton's system. Sufficient data being supplied, as they are in the premises of a syllogism, we ought to be able to determine, as to each of the three syllogistic propositions, in which of the two wholes it predicates. E and O are easily dealt with as propositions of inclusion, when the contradictory of the predicate is taken as the class. But how as to $\frac{1}{2}$ E or $\frac{1}{2}$ O, if these present themselves? Are they in any way thinkable, as predication either in extension or in comprehension?

NOTE II.

Hints for the Interpretation of Propositions.

I. When forms of expression, designed for the excitement of imagination or emotion, are to be logically used, they must either be translated into assertions expressive of pure thought; or, if any of the ideas denoted cannot be so translated, these must be neglected, as not logically cognizable. Thus, all figurative phrases must be brought within our grasp by direct assertion of the relation they imply: "All flesh is grass," finds its equivalent in "Man is as fading as grass." Exclamations, again, are assertions intensified in meaning through indications of emotion. The emotive or intensive phrase may be made logically available when it is not a sign of quantity, but not when it is: "How miserable are some men!" is fairly interpretable into "Some men are very miserable;" "How many men are miserable!" cannot find a direct equivalent. Again, assertions made passionately, fall often, both in oratory and in common speech, into the form of question: the Interrogation is the favourite figure of Demosthenes. The assertion extricable is the answer; the quality of which is opposed to that of the question.

II. When we pass to assertions which may be taken to be already expressions of pure thinking, the first point that arises is the character of the *Copula*, raising the question of Modality. Pure categoricals are such as have been considered in the text. Modals have, as a copula, not the verb "to be" by itself, but this with some phrase which adds to or restricts its meaning. There seems to be no reason for questioning the sentence which excludes modals from logical treatment; but they are often interpretable into a shape which gives effect to the modal element, through its incorporation into one of the terms.

1. Treated in the most systematic way, modality is of three kinds, giving Kant's Judgments Problematical, Assertory, and Apodeictic (or Demonstrative). These are founded on the relations of possibility, reality, and necessity, and are expressible in the copula (affirmatively) by "may be," "is," and "must be." When considered psychologically and metaphysically, these varieties of thought are very important. In this view, "may be" is an expression, not of knowledge, but of a doubt which may or may not lead to knowledge. The imperative "must," on the other hand, seems to give voice to the only form, in which we can directly think the necessity attending our immediate cognition of *a priori* truths. That necessity cannot pass into the form of universality through "all," until we have both represented the primitive cognition, and determined, rightly or wrongly, the sphere in which the law works. When this step has been taken, the "must" becomes quantitative; and the copula may be "is." Now, unless when the method next to be noticed is accessible, the hint just thrown out appears to indicate the only manner in which the threefold modality can be regarded as bearing on pure categorical predication. The "is" being accepted as the copula, the "must," when interpretable at all under this condition, signifies the universality of the subject; the "may be" its particularity. "Body must occupy space;" that is, "All bodies occupy space." "Body may be visible;" that is, "Some bodies are visible, some (as gases) are not."

2. Modality is frequently constituted by qualifying phrases, which (as is often true also of the "must," and "may") are easily transferable from copula to predicate. "John—is probably—dead," becomes pure as "John—is—a person probably dead;" and this transformation of the proposition would commonly, though not invariably, fit it for use in a given case.

3. The most stubborn kind of modality is made by the element of *time*, which often resists successfully all attempts at displacement. The logical copula merely connects subject and predicate, on the hypothesis that both denote objects which do or may exist. "X is Y" has logically no more meaning than this: "If X is, and if Y is, X is Y." Even our "is," because suggesting the idea of time, is not theoretically perfect as a symbol of the relation between the terms: there is a strong temptation (which must be resisted for avoidance of counterbalancing evils) to the substitution for it of mathematical signs like the =. But, when an assertion is made as to the past (and the same thing might be said of the future), we cannot, by any exertion, shake out the actuality which clings to the root of it. Allegations of historical facts cannot become pure categoricals, without destruction of their essential import. The truth is, that narrative propositions, *qua* allegations of past individual facts, are not adequate data for reasoning that embraces classes of objects and their laws. Nor are they really so used. The simplest general reflection that can insinuate itself into the body of a history, will, if founded on an incident or characteristic appearing in the story, be found to have silently transformed the individual fact into an instance exemplifying some principle, holding for all time, and expressible, though not expressed, in pure categorical form. When, in historical writing, an inference is drawn from one individual fact to another, it might be logically tested in a fashion which, though of the roughest, and involving inquiries extra-logical, may sometimes be useful. It will, in particular, save needless trouble, when we encounter an argument in which the copula does not always appear in the same tense. Let us ask ourselves, after having examined the matter of the propositions, whether the change of time is essential or inessential to the mutual relations of the terms. If it is inessential, we may shut our eyes to the discrepancy. The test is stood successfully by such an argument as this: "Sages deserve fame (that is, always); Socrates was a sage: therefore Socrates deserved fame (or even Socrates deserves it)."

III. In a third class of propositions, the difficulty arises from the *Terms*. Each proposition of this class is resolvable into more propositions than one; though it is a question, to be answered only from scrutiny of the use the assertion is put to in a given case, whether it is to be so resolved, or to be treated as one assertion. Such propositions are describable by old names, as "*propositiones compositae*," or compound; or as "*expansiones*," in respect of their

Doctrine of susceptibility of analysis; and some of them have, by certain logicians, been regarded as a species of modals.

propositions.

All such forms are instances of the abbreviations to which language has recourse, in its vain endeavour to keep pace with the rapidity of thought. The varieties are as indefinitely numerous as the kinds of the occasions. The following are a few of those which occur most frequently in immediate relation to trains of reasoning:—

1. A Hypothetical proposition is the condensed expression of an inference, without categorical assertion of the premise: "If X is Y, Y is Z." The propositions called Inferential and Causal have the same import, with this difference, that they categorically assert the premise, sometimes through a participle: "X is Y, therefore Y is Z: Y is Z because X is Y: X, being Y, is Z." If the inferential relation appears on the face of the compound proposition, it may be dealt with logically: if it does not, if it merely asserts the connection of two facts not formally related through a law of thought, the relation lies beyond the logical sphere.

2. A Disjunctive proposition, if affirmative, is equivalent to the assertion that one or another of two or more categorical propositions is true: "A is either X, or Y, or Z: either X, or Y, or Z, is A." If negative, it denies each of the alternatives: "A is neither X, nor Y, nor Z: neither X, nor Y, nor Z, is A."

Both hypotheticals and disjunctives will have to be treated more closely in a further stage of our progress.

3. The propositions oftenest called Copulatives are categorical affirmatives, in which either term, or both, are resolvable into simpler terms, co-ordinates of each other: "A is X, and Y, and Z: X, and Y, and Z, are A." If the terms are common terms, A may be the name of a class, X, Y, and Z the names of sub-classes constituting it; and in this case the proposition is treatable as an equivalent of the affirmative disjunctive. Such a proposition is an A². Very frequently this analysis is inapplicable: "Honesty and industry are virtues: industry is commendable and self-rewarding." But an assertion having the same form is often, in reality, one assertion only, the complex term being taken collectively: "Honesty and industry give promise of success;" that is, all combinations of honesty and industry give such promise.

4. Exclusive propositions are marked by such phrases as "only," connected with the predicate, and always (if we mistake not) truly referable to it: "All X's (or some X's) are the only Y's."

It has already been observed that, in making affirmative assertions of this sort, we really bring into actual use the questioned forms A² and I²; and it has been pointed out, likewise, that another proposition may be held as implied. The full expression of the thought, in this view, gives these two predications: (1.) "All (or some) X's are some Y's:" (2.) "Things which are not Y's are not X's."

A proposition exclusive by negation would be such as this: "The X's (or some X's) are not the only Y's." Such an assertion is not expressible by one proposition, in any of the eight forms of predication: it is not so even by $\frac{1}{2}I$ or $\frac{1}{2}O$, unless the "some" of the predicate were to be interpreted definitely. Its whole signification is reachable only through analysis into its two factors: (1.) "All (or some) X's are some Y's:" (2.) "Some Y's are not any X's."

5. Exceptive propositions are marked, in the subject, by phrases like "but, except, unless, besides," which are equivalents of "not;" while "only," too, has certainly an exceptive force (of negation) when joined with the subject.

Accordingly, the affirmation "All objects besides the X's are Y's," is directly equivalent to the affirmation, "All objects which are not X's are some Y's (= All Not-X's are Y's)." But it presupposes or implies also the negation: "The X's are not any objects which are Not-Y's (= The X's are not Not-Y's)." So the negation, "No objects but the X's are Y's," is exponible into the expressed negation, "No objects not X's are any Y's," and the implied affirmation, "All the X's are some Y's."

When either exclusive propositions or exceptives appear in a chain of reasoning, it will almost always be found, that the expressed factor is that for the sake of which the allegation is introduced, and that no use is made of the implied one. But the implication requires to be remembered, in case of its emerging so as to cause a fallacy; and confused thinking may be made still more confused, through these or any other of the complex kinds of propositions.

6. A Comparative proposition presupposes another, with which it might stand undissected. The assertion that "Washington was a greater man than Napoleon," assumes that "Napoleon was a great man."

7. Restrictive propositions are not always analysable on the same principle. Sometimes such a proposition is, even in the shape in which it is given, a true and simple categorical, having a term which denotes (perhaps not so neatly as might be) a very complex idea. Often,—as in the case of the "reduplicative" of the schoolmen,—it is virtually an inference. "Man, so far as he is an ani-

mal, is mortal," seems fairly interpretable into "Man, being an animal, is mortal;" and this, again, is a causal proposition.

IV. Sometimes there insinuate themselves into reasoning, assertions of a kind, which it is not difficult to dispose of when their true character is understood. Their distinctive feature is not condensation, but expansion. They are best illustrated by propositions usually called Adversative, which assert, in any of several ways, a contrariety between one proposition and another.

1. The reason for adoption of the adversative form is frequently the desire to use that excitative power over imagination and feeling, which is possessed by the antithesis. In such a case, it will seldom be possible to determine the logical bearing of the proposition, until it has been thrown into another shape; and the choice may lie between any of several shapes, one of which only will exhibit the intended function of the proposition as a step of inference. Thus, if a proposition like this were to find its way into argument: "Life is short, but art is long," it would probably have to be interpreted as meaning, either that life is too short for the mastery of art; or that the complete study of art is too arduous for one short human life.

2. The adversative factor of the proposition may be merely explanatory or limitative. It may have been introduced in order to make it quite clear, either that certain cases are excluded from the scope of the principal assertion, or that certain cases are included in it. The context ought to show plainly, which of the two factors is the assertion founded on in the reasoning, and which is a mere gloss not entering into the argument at all.

CHAPTER II.

The Laws of Categorical Predication through Common Terms.

44. Let two terms be given, with the postulated explanation; and, the question of inference being postponed, let it be required only to predicate or form propositions with terms singular and common. Logic can work the problem no further, than by exhibiting all the propositional forms in which it is possible to combine the terms, whether affirmatively or negatively. Which of the propositions, if any, would be true in respect of the relation between the objects signified by the terms, or which false in respect of that relation, is a point to be determined, as to each proposition considered by itself, through knowledge of the matter, and not otherwise.

When any of the terms are singulars, the propositional scheme which has been examined must, as framed with exclusive reference to common terms, be in part inapplicable. But, the singular term being treated as a common term distributed, forms will arise which are virtually equivalent to certain of our six. Some of the six are without any such parallels.

In the first place, both terms may be singular. In this very simple and unfruitful case, the only possible predications are equivalents of A² and E.

A greater variety of forms, as well as a wider possibility of inference, is produced by Mixed Predication, in which the given terms are, the one a common term, the other a singular. Now, we do not naturally think a singular term as predicate, either affirmatively or negatively, when the other term is common. Accordingly, with reference to the functions of the terms, a distinction may advantageously be taken, between forms which do spontaneously present themselves, and others which are gained only through logical analysis, or through a process of reflection virtually amounting to it.

1. Two of the six forms are in all cases excluded: I, by the impossibility of particularizing the singular term; A² by the impossibility of thinking an individual as constituting a class.

2. Equivalents of the other four forms are admissible, but under dissimilar conditions. (1.) The E is possible with either position of the terms. It occurs naturally and continually with the singular as subject: "John is not an (any) archbishop." With that term as predicate it occurs, per-

Doctrine of propositions.

Doctrine of propositions.
 { haps, never, unless as the result of a scrutiny for purposes really logical; as, for instance, when we wish to change the form of a given argument. Technically speaking, it arises through conversion. (2.) The occurrence of A is both possible and incessant, the singular being the subject: "John is a (some) good man. (3.) The I², possible only when the singular is the predicate, is in the same predicament with the second variety of the E. It is, although the received logical rules disguise the fact, the just converse of A. (4.) The O is possible with the singular as predicate; but this, the weakest of all predicative forms, is stricken with more stubborn barrenness through the inflexibility of the singular. Probably the proposition is without example in ordinary and unanalytic thought; and its uses of any sort must be very rare.

These mixed forms are evidently ruled, with exceptions neither many nor obscure, by the same laws which govern predication through terms all of which are common. Inference from them, also, both immediate and mediate, is similarly placed towards inference proceeding purely through common terms. It seems sufficient, therefore, to have indicated, as here, the forms of mixed predication. No attempt will be made to assign for them any special laws of inference.¹

Predication, through common terms, in extension and in comprehension.

45. Our attention will henceforth be directed exclusively to Predication and Inference through Common Terms.

Predication through common terms is limited, in more quarters than one, by a corollary already noticed as following from the primary law of the concept, that is, the Inverse Ratio of the terms.

We cannot, in one and the same judgment, analyse a concept, or make a predication giving the result of the analysis, in both of the wholes which together make up the synthetic totality of the concept. "We must either think explicitly in extension, and imply comprehension; or think explicitly in comprehension, and imply extension."

Every term, with which there are given to us materials permitting predications of it in both wholes, must be thought as standing in an ordained series, of which it is not either extreme. Upwards from it in extension there must stand terms, one, or more than one, which are names of classes that contain, step by step, more objects, because the objects possess, step by step, fewer attributes. Downwards from it in extension there must stand terms, one, or more than one, which are names of classes that contain, step by step, fewer objects, because the objects possess, step by step, more attributes. The term from which we start takes, naturally, as antecedent, the function of subject in predication. We may find predicates for it by looking either upwards or downwards. But we cannot look both ways at once: and we gain one predicate or set of predicates by searching in

the one direction, another predicate or set of predicates by searching in the other.

The result, then, is this. Every proposition, framed with two common terms, must be either a *predication in extension* or a *predication in comprehension*. It must be, either, a predication of the subject in (or out of) the extension of another term, which is the predicate; or a predication of the subject in (or out of) the comprehension of another term as predicate. It cannot be both. We predicate of a term, as subject, in the extension of the predicate, by affirming of it a term denoting a more extensive class. We predicate of a term, as subject, in the comprehension of the predicate, by affirming of it a term denoting a less extensive class. Thus, of the subject-term "animals," we predicate in extension by affirming of it "organized beings," as predicate: we predicate of it in comprehension by affirming of it "birds."

Suppose a proposition is given, but only one. If, as in those examples, we happen to know the actual relations of the objects denoted by the terms, we can say, peremptorily, in which of the two wholes the predication is. But the question cannot be determined in the absence of such information. No assistance is yielded by any forms of expression, either usually occurring or at all likely to occur. Nor would it be easy, if so much as possible, to devise technical expressions adequate to the purpose. Abstract phrases, into which predications in comprehension are analytically resolvable, are in very many instances not extant: and it seems impossible so to mould them, that they shall fully denote the quantity of the terms. We think and speak, by preference, concretely; and we thus suggest predication in extension. If an assertion has really the opposite character, the fact must be inferred from data which are wanting in the case supposed. We say, in extension, "All animals are organized beings." But we say, likewise, in comprehension, "Some animals are birds."¹

46. Suppose, then, that there are given two common terms, under the conditions postulated, but without any further datum. Logic, if called on only to form one proposition, can determine nothing more than this: that the only alternatives of predication are yielded by A, I, E, and O; or by A² and I², also, if these are admitted.

Much closer determinations, indeed, can be reached, if given in an ordained series. any one of those propositions be supposed to be formed, and assumed to be either true or false. All the forms are so related to each other, through direct applicability of the logical axioms, that the assumed truth or falsehood of any one of them warrants us, with certain restrictions, in asserting the falsehood or truth of each of the others. These mutual relations are, by many logicians, considered, under the name of Opposition, as affections of the proposition; and the laws governing them are treated as laws of predication.

Strictly taken, this evolution of one proposition from another is inference, not mere predication: and other kinds of inference from one proposition have also to be examined. All will be taken together at the next and last step in our study of the proposition.

¹ Here arises a psychological question. It was noted, in the introduction, that, in the German nomenclature, the word "thought" does not include any cognition that is not discursive. It might have been added that, by Kant, the name is specified a step further, so as to signify only "cognition through concepts." If the word is to be thus narrowly understood, it can scarcely cover predication or inference in which any of the terms are singulars; yet these are logically treatable, and must therefore be admitted to signify thoughts. Some of the Kantist logicians have sought to remove the difficulty, by maintaining, that the significance of a singular term becomes a true concept, whenever it is an element in a judgment logically analysable. But, surely, such a theory ignores the distinctive character of the concept. The singular term is the symbol of an image (*Bild*), representative of an intuition (*Anschauung*) real or possible. That the representation is partial, incomplete, is nothing more than what seems to be true of every image. That the representation, if denoted by words, is symbolic, is a fact which cannot change its objective reference. Conception is necessarily symbolic; but symbolic cognition is not necessarily conception. Some of Mr Mansel's speculations bear closely and instructively on this question.

¹ The only available forms of expression (and even these but partially sufficient), would be gained through explicit signature of the quantity of predicates.—In dealing with the references which concrete and abstract thinking severally have to the two wholes of the concept, Mr Karslake has broken up ground which may hereafter prove to be very fertile. Again, the combination of concrete terms and abstract in the same proposition, the one as subject, the other as predicate, is, if it occurs spontaneously, a symptom of confused thought. If it is introduced wilfully, as it sometimes is in the logical treatment of given examples, it generates the same confusion, of which it is a natural expression. (See Hamilton's *Discussions*, p. 646.) "Whiteness," says Occam, "is not white."

Doctrine of:
proposi-
tions.

But the difference between predication and inference is nothing beyond a difference in the form of the data. We predicate in framing a proposition from given terms: we infer in framing a proposition from one or more given propositions. It is a doctrine to be insisted on, that inference is merely predication taking place in more steps than one; and that all the laws of inference are but variations, designed to meet greater or less complication of materials, of the logical axioms, which are strictly laws of predication.¹

This is one reason for considering exactly, from the position now reached, the laws which govern the formation of propositions from given terms, in a class of cases differing considerably from that which has just been laid aside. Let there be given common terms, either two, or more than two; and let there be given with them, not the quantitative signs, but, which is much more, an explicit *ordination of the terms*. The ordination may be indifferently in extension or in comprehension, provided only we be informed in which of the two it is.

Is such an ordination ever actually given? And is it recognisable without interpretation of the terms? Both questions must be answered, in the affirmative. On the one hand, it is, as we shall immediately see, the datum of every definition and of every logical division. On the other hand stands a fact which concerns the logician still more nearly. In every syllogism, having premises which allow any inference, there are given three terms: and, if these terms are common, there is implied, and easily extricable, an ordination of these, the discovery of which does not require any scrutiny of their meaning. The ordination being gained, we may, by combining the terms two and two, form, not only the conclusion of the given syllogism, but also several or many other propositions. All these results are accessible through canons, which are nothing but corollaries, the simplest and most obvious, from the principle of the concept, the law of the inverse ratio.

We shall have laid the broadest and firmest foundation for a just understanding of the character of syllogistic reasoning, if we satisfy ourselves, at present, that all syllogistic conclusions are attainable through direct comparison of the terms of the argument, without the explicit statement of the relations of the terms in the form of propositions. All Inference, whether Immediate, that is, from one proposition, or Mediate, that is, from propositions more than one, is merely an explicit assertion of the implied relations of terms. The process is called inference, when the relations of two or more terms are given, as already explicated in propositions; and when the problem proposed is the analysing of those propositions, for the purpose of discovering what other relations are implied in the assumed ones, and may, therefore, be expressly deduced from them. The process would not be called inference, but predication, if the relations of the terms were given as unexplicated; which is the case when the terms are only described for us as holding certain places in an ordained scale. The theory of reasoning is not reduced to its utmost simplicity until it has been made evident, that the process, into whichever of the two forms the data may throw it, is really one and the same.

Therefore it is desirable that we should, at once, put ourselves in possession of the laws which regulate predication through common terms, both in extension and in comprehension. Another reason is this. When we come to study inference specially, its two kinds, immediate and mediate, must be taken separately. Some of these laws of predication bear on the one kind of inference, some on the other;

consequently, if not now collected, they would appear only as isolated theorems. Some of them, too, would not come clearly into light at all.

Doctrine of
proposi-
tions.

I. Predication in Extension.

47. Let there be given, as ordained in extension, from highest to lowest, a series of two or more terms: and let it be required to predicate with these in extension, both affirmatively and negatively; that is, let it be required to assert of one term, given as subject, that it is in, or out of, the extension of another term found as predicate. The possibilities of affirmation and negation, and the quantitative determinations of the terms, are set forth in the following rules.

The laws of
predication
in extension:
affirmation and
negation.

(I.) AFFIRMATION.

I. Of any subordinate term, there may be affirmed any term positively superordinate to it, either immediately or mediately. This is the one universal canon.

Co-ordinates are here excluded from consideration. All the objects of the subordinate class are, through the relations involved in the character of concepts, included in each of the classes positively superordinate to it. All the objects which, in respect of a certain attribute, are called by the name of the subordinate class, are some or other of the objects which, in respect of other attributes, receive the names of the superordinate classes. If the given series, ordained from highest to lowest, be X, Y, Z, we may affirm that "All the Z's are some Y's;" that "All the Y's are some X's;" and that "All the Z's are some X's."

II. Of a subordinate term, given as distributed, a positive superordinate may be thus affirmed, through any of several presuppositions; and these, if successively engrafted on each other, will throw the process into several different forms.

(1.) Of a subordinate term there may be affirmed, universally, any term thought as superordinate to it, immediately or in the first degree. There is thus formed a simple predication of identity in A; as, "All the Z's are some Y's;" or, "All the Y's are some X's."

(2.) In such a proposition there is implied another. The subordinate being given as distributed, there may be affirmed of it, as undistributed, the same superordinate. If all the objects of the lower class are included in the higher class, some at least of them must be so. We have thus from one predication of identity derived a second, from an A an I: "Some of the Z's are some Y's;" or, "Some of the Y's are some X's." The process is an immediate inference by subalternation.

(3.) Of a subordinate term (distributed or undistributed), there may be affirmed, in A or I, a term thought as superordinate to it mediately in the second degree; that is, a term thought as immediately superordinate to the immediate superordinate of the given term. The objects (all or some) of the given class Z are identical with some or other of the objects of the class immediately superordinate, Y; and all the objects of the class Y are identical with some or other of the objects of its immediate superordinate, X: therefore, necessarily, there are, in the intermediate class Y, objects which, in respect of one attribute, receive the subordinate name Z; while, in respect of another attribute, they receive the superordinate name X. If all the identities which are thus discoverable are explicitly enunciated, they yield the three following propositions:—"All (or some) Z's are some Y's (A or I)"; "All the Y's are some X's (A)"; "All (or some) Z's are some X's (A or I)." The third assertion of identity is elicited from the first and second, considered in relation to each other. "The Z's (all or some) are identical with some or other of the Y's (A or I); and all the Y's are identical with some or other of the X's (A or I); therefore the Z's (all or some) are identical with some or other of the X's (A or I)." In this explicated

¹ See, afterwards, *Doctrines of Inference*, chapter i.—Compare Mansel, *Prolegomena*, pp. 196, 207. By Twisten (*Die Logik, insbesondere die Analytik*, 1825), all the forms of thought are exhibited in an ascending series, whose members increase in complexity according to the character and number of the data.

Doctrine of form of all the steps, the process is a mediate inference of the least complex kind. The three propositions constitute an Affirmative Syllogism.¹

(4.) Of a subordinate term (distributed or undistributed), there may be affirmed, in A or I, a term thought as superordinate to it in any degree beyond the second. When such a process is evolved at every step, it is found to consist in repeated predications of identity: it is, in fact, an extension, through higher degrees, of the process of syllogistic inference. The series of propositions is called by logicians a Sorites; the ultimate conclusion of which must, on such data as these, be affirmative, but may be either universal or particular.

(II.) NEGATION.

As affirmation in extension rests on the law of identity, applied to objects thought as included in classes, so negation in extension rests on the law of difference, applied to objects thought as excluded from classes. If, of either Z or Y, I am entitled to deny X, this must be because I think of X as being something different from Z or Y: X must be thought as equivalent to Not-Z or Not-Y. It follows, that negation is not applicable to a series of terms positively ordinated, unless by substituting, in the predicate, the contradictory of a term for the term itself; as if, for "All X's are some Y's," we should take the equivalent negation, "The X's are not any Not-Y's."

But negation finds a place without this expedient, as soon as there is incorporated into our positive series of terms a Co-ordinate of any one of them. Terms co-ordinate are thought as being, not indeed absolutely, but within the given sphere of thought, contradictories of each other.² Thus, if our thinking is limited by its hypothesis to the class of objects which we call "organized beings," that class may be further thought as containing only two sub-classes, "animals" and "vegetables;" hence all organized beings which are animals, are thinkable also as being "not-vegetables;" and so the opposite way. Co-ordinate classes must admit of being so thought, if they are to obey the law which makes such classes to be exclusive of each other. Any two classes being thought as co-ordinate, all the objects of each are thought as having some attribute wanting in all the objects of the other. Therefore any object which is in the one class cannot be in the other: the two terms must be names for two groups of objects totally different.

One special remark is required. If we either know the meanings of terms, or have received an ordained series, we can determine peremptorily, as to any proposition framed with a higher term and a lower, in which of the two wholes of the predicate the predication is made. But every proposition denying one co-ordinate of another, may be regarded as being either in extension or in comprehension: for each of the terms excludes the other in both relations.

The rules cannot conveniently be grouped, like those for affirmation, under one canon covering all possible cases.

¹ Here, accordingly, we hover very near to debateable ground, which must afterwards be fairly traversed. If the terms of a conclusion are thought as ordained in one degree, it is reached through simple subalternation. But the question may be raised, even now: whether, supposing it is only through inclusion in Y that we do actually think the inclusion of Z in X, both of the steps constituting the premises must necessarily be thought explicitly in the form of judgments; or whether one of them may not, without detriment to the process, continue unexplicated and only implied.

This inevitable limitation of the sphere, within which the laws of difference and excluded middle must work when the terms constitute an ordained series, is strongly put by Trendelenburg, and grounds his attack on division by dichotomy. (See his *Logische Untersuchungen*, vol. ii., p. 317, and elsewhere; and his *Elementa Logices Aristotelicae*, § 58.) It is also very firmly apprehended by Mr De Morgan. (*Formal Logic*, p. 38, and *passim*.)

But, throughout all of them, the co-ordinate takes the place of which, in the affirmative rules, was held by one of the superordinates. Let X, Y, Z, be given in ordination as before, and let a, b, c, be co-ordinates of those three terms severally.

I. Of any common term, there may be denied universally any term thought as co-ordinate to it.

There is thus formed, on principles already explained, a simple predication of non-identity in E: as, "Any X's are not any a's:" and so of the other terms.

II. Of any common term, there may be denied particularly any term thought as co-ordinate to it.

The process is an immediate inference by subalternation, yielding an O: as, "Some X's are not any a's." Its principle is that of the corresponding affirmation.

III. Of a subordinate term (distributed or undistributed), there may be denied any of the co-ordinates of any of its superordinates.

There arise, in this way, when all steps are explicated, processes of mediate inference, corresponding to those for affirmation, only with substitution of a co-ordinate for the superordinate of a superordinate. The principle is very plain. The subordinate is included in the superordinate; from the superordinate its co-ordinate is excluded: therefore the co-ordinate is excluded from the subordinate.

(1.) Of the subordinate (distributed or undistributed), there may be denied, in E or O, any co-ordinate of its superordinate in the first degree.

A co-ordinate of Y will be signified by b, which is thus equivalent to "Not-Y." Our terms will then yield these three predications, the first of identity, the other two of non-identity: "The Z's (all or some) are some Y's (A or I); any Y's are not any b's (E): therefore the Z's (any or some) are not any b's" (E or O). The series of identities and differences is self-evident. The three propositions constitute a Negative Syllogism. Accordingly this kind of syllogistic inference is, when analyzed in reference to the wholes of the terms, resolvable into an ordination having a different character from that which produced affirmative conclusions. The terms rise by one step only; and the higher term of the two, instead of rising by inclusion into a third, diverges by exclusion into the parallel or co-ordinate.¹

(2.) Of a subordinate term (distributed or undistributed), there may be denied, in E or O, any co-ordinate of any term superordinate to it in any degree beyond the first. Such a process yields a Sorites, whose conclusion may be universal or particular, but must be negative.

II. Predication in Comprehension.

48. We must, and do, predicate in comprehension as well as in extension.

Not only, however, is it true, as has already been remarked, that we naturally express ourselves in those concrete forms which are appropriate to extension; but, further, we never do, naturally or spontaneously, either think or

The laws of predication in comprehension: affirmation and negation.

¹ It does not seem possible to escape from this result of the analysis, if the negative forms are to be preserved. Nor can it be said to trench, in the slightest degree, on that more exact analysis of the Syllogism, which will, by and by, be attempted on the same principle.

But, if it is insisted on that the syllogism shall exhibit the X, Y, Z, in a regular scale of positive ordination, the negative syllogism may be made to do so by being transformed into an affirmative one. This is effected through a process which we shall immediately become acquainted with,—Contraposition. The excluding of the subject from the sphere of the predicate, is equivalent to the including of it in the sphere (indefinitely wider) of the contradictory of the predicate. The proposition "The Y's are not any b's," thus becomes "All the Y's are some Not-b's." Our negative syllogism might, through this change, become affirmative thus: "The Z's (all or some) are some Y's (A or I); all the Y's are some Not-b's (A): therefore the Z's (all or some) are some Not-b's (A or I)." Our ordained terms are now these: "Not-b, Y, Z;" and the analysis of the affirmative syllogism is exactly applicable.

Doctrine of
proposi-
tions.

to speak in systematic pursuance of that course of thought which predication in comprehension would signify. We think from objects as data; and we scrutinize their attributes only as enabling us to place the objects in classes, to think of them as amenable to laws. Predication in comprehension does not emerge spontaneously in reasoning, unless in conjunction with predication in the opposite relation, and with a view to the ultimate establishment of that other.

So far in the background does predication in comprehension lie, that it is only modern logicians that have given systematic attention to its bearings on any doctrines of the science; while even of these there is only one who has brought to light its highest results. The four received forms of propositions, on which exclusively the received logical system rests, do not allow correct expression for this relation of the concept: and inferences bearing on it, whether mediate or immediate, require one additional form before they can be enunciated so that their validity shall be self-evident.

With anticipation, therefore, of uses to be found hereafter, it is well that the laws of predication in comprehension should be briefly set forth. They do not require to be elaborated so formally as those of extension, with reference to which, mainly, the laws of inference will be expressed. But the right apprehension of them demands patient attention, on account both of the smallness of the assistance which the orthodox systems give towards it, and because of the difficulty we all have in seizing this relation distinctly.

If we adopt, for exemplification, the same three symbolic terms as before, the ordination of these must, by reason of the inverse ratio of the wholes, take place in the opposite order. Ordinated in comprehension, from highest to lowest, they will stand thus: Z, Y, X. It will be convenient, also, to illustrate the sequence by predication with significant terms: as these, for the three in their order:—"Man, animal, organized being."

(I.) AFFIRMATION.

I. Of any term subordinate in comprehension, it is true, first, that there may be affirmed of it any term superordinate to it in the same relation; secondly, that the affirmation must be particular; thirdly, that the affirmation must, if its interpretation is to be exhaustive, be held to have its predicate distributed, that is, to be in I² not in I. The proof is easy.

Let our affirmation be this: "Some Y's are Z's: some animals are men." When we thus, in respect of comprehension, ascend in passing from subject to predicate, we do, by the same step, descend in extension.

(1.) From whichever of the two sides we regard the terms, it is clear that affirmation is possible. The attribute, whose possession by certain objects is intimated by the subject, is possessed also by all the objects named in the predicate. Terms rise in comprehension, and fall in extension, not by signifying fewer and fewer attributes, but by adding, at each step, a new attribute to the first. There cannot but be objects nameable by both terms.

(2.) The increase in signified attributes carries with it a decrease in contained objects. The predicate, as implying one attribute more than the subject, cannot completely fill the extension of the subject: the subject-class must contain, besides the objects that are in the predicate-class, those objects also which are not in it as not possessing its attribute. The affirmation must be particular.

(3.) The distribution of the predicate becomes most promptly visible if we first affirm with the same terms in extension. We thus gain the assertion: "All Z's are some Y's: All men are some animals." The counter-relation is incompletely rendered, if it is held to yield anything

less than an exact and complete reversal of this affirmation. The affirmation in comprehension must be an I²: "Some Y's are all Z's; some animals are all men." The nature of the ordinative relation elicits clearly the same signification. It is true, of some of the Y's, not that they are a part of the class Z, but that they constitute the whole of it: there are, by the hypothesis, no Z's besides those that are Y's. There are certain objects which are "animals:" but these we can call only "some animals;" because there are other animals besides them. Of those objects it is not true, that they are the same objects with "some" of those we call "men," and different objects from "some other" men: it is true that they are the same objects to "all" of which we give the name "men." The interpretation of the affirmation as I, "Some animals are some men," is doubtless safe, as asserting within the truth. It might, also, be formally justifiable, if we were to read the quantitative sign as "some at most." But, first, this is not the logical reading; and, next, if it were adopted, the affirmation would violate the sound precept of the logicians—that every proposition shall explicate completely the relations implied in its data.

II. The affirmation being already particular, subalternate inference from it is not possible according to the received scheme. But, if we are to adopt the I², we must hold it as admitting a subalternate, through a formal limitation of the predicate, implying a real limitation of the subject also. This subalternate is just the I, which usually takes the place of the I². "Some animals are all men;" therefore, also, "Some animals (but a narrower 'some' than the first) are some men."

III. Mediate inference is possible through affirmation in comprehension, as widely as through affirmation in extension. But it is expressible only through the admission of I², if the propositions are to contain on the face of them evidence of the validity of the process.

It is sufficient, for the present, to set down, in the relation of comprehension, the universal mode of the same syllogism which already exemplified the relation of extension, together with a parallel in significant terms. "Some X's are all Y's (I²); some Y's are all Z's (I²): therefore, some X's are all Z's (I²)." "Some organized creatures are all animals; some animals are all men: therefore some organized creatures are all men." Breaking loose from almost every formal rule of the syllogism, this argument does not violate any one of its philosophical laws.

(II.) NEGATION.

I. II. Co-ordinates, when considered without reference to other terms in a series, are indifferent to the two wholes of the concept. It follows, that the same two rules which stand first and second for predication in extension, may hold, and for the same reasons, a corresponding place here.

III. Of a term subordinate in comprehension there may be denied any of the co-ordinates of any of its superordinates. But the denial must be particular.

In respect of the quality of the proposition, this rule is proveable by the same considerations which established the parallel rule in extension. The limitation of quantity requires no illustration beyond those already given in this section.

In negation, as in affirmation, the mediate inferences thus formed might be, though they never have been, carried upwards from the simple syllogism into the sorites.

III. *The Transference of Predication from Whole to Whole.* The laws regulating the transference of predication from whole to whole.
49. For the perfecting of our insight into the character of predication in extension and comprehension, it is necessary to consider cursorily a relation which must afterwards be scrutinized more minutely, as yielding one of the kinds of immediate inference.

Doctrine of
proposi-
tions.

Doctrine of propositions.

It is self-evident, that we may not only predicate in either whole, but also transfer a given predication from the one to the other. It seems to be almost equally plain, that the process which is called Conversion is nothing else than such a transference. Its theory is not made complete until it is contemplated in that aspect. The rules of the process will immediately be assigned; but the foundation for them ought to be here laid, in a few theorems, which appear to require little, if anything, either of proof or of illustration.

(1.) Any two common terms may be ordained in either whole; and ordination in either implies and yields ordination in the other.

(2.) Consequently, any two ordained terms may yield either a predication in extension, or a predication in comprehension.

(3.) By reason of the inverse ratio of the two wholes, the terms must, in the two propositions, discharge opposite functions: that which is subject in the one must be predicate in the other. If X is in the extension of Y, Y must be in the comprehension of X.

(4.) Consequently, again, if there be given a proposition which predicates in the one whole, it may, by a simple reversal of the functions of the terms, be transformed into a proposition predicating in the other whole.

(5.) The process of conversion is nothing else than such a transference of predication from a given whole into the other. The special rules of conversion find their principle in the law of the concept: they are merely adapted forms of those corollaries of that law, which regulate predication in the two wholes.¹

CHAPTER III.

The Laws of Definition and Division.

The form and character of definition and division.

50. Affirmative propositions, having both terms distributed, have uses which give them a special scientific and philosophical value: A² is the form necessarily assumed by Definitions and Divisions correctly constructed. The character, likewise, of definition and division, is dependent on the doctrine of the concept. A definition is nothing else than a development of the comprehension of a common term, through terms lying above it in extension. A division is a development of the extension of a common term, through terms lying above it in comprehension. Both may be said to have for their purpose the making concepts more distinct; the one by evolving concepts in whose extension the given concept lies, the other by evolving concepts in whose comprehension it lies. It is a consequence flowing necessarily from the mutual and inverse relation of the two wholes of the concept, that its comprehension shall be made more distinct through its extension, and its extension through its comprehension. We determine what are the attributes of given objects, by finding what classes they may be thought in: we determine what objects are contained in given classes, by finding what attributes they may be thought as possessing.²

¹ This view of the character of Conversion does seem, not only to flow, by consequence obvious as well as necessary, from the principle of the concept, but to be necessary for thoroughly grounding the theory of the process. But certainly, so far as we know, it has not been stated by any, even of those recent logicians by whom, in this country and in Germany, the mutual relations of extension and comprehension have, in their bearing on other logical doctrines, been most deeply probed.

² Division and definition have long been thus analyzed by the German logicians; the latter as an evolution of the comprehension of a concept, the former as an evolution of its extension. Their theory of division is almost complete: their theory of definition is not so near to being so. It does not seem correct to say, as it is said by some (not all) of them, that the concept is made more "clear" by division, more "distinct" by definition: in the appro-

Doctrine of propositions.

The three stages in the development of ideas.

51. Our thinking of objects may pass through very many stages, on its way towards becoming a knowledge of the objects. The principal of those stages may be said to be three; and to these have been assigned names, the technical meanings of which, being specifications of the ordinary meanings, require some explanation. Our ideas of objects may be either Obscure, Clear, or Distinct.¹ *First*, Our idea of an object is obscure, when we are not able positively to distinguish it from other objects; when we are unable to determine the question of identity or non-identity. Such a thought of the object is not knowledge of it in any sense. *Secondly*, Our idea of an object is clear, when we are able to distinguish it from other objects; when we are able to determine the question of identity or non-identity. Our thinking of individual objects must rise to this point before we can be said to know them: and, while objects are contemplated merely as individuals, this point cannot be transcended. But, in whatever light objects are regarded, clearness in our thinking of them must have place if any further step is to be taken. *Thirdly*, Our idea of objects is distinct, when, besides being able to distinguish them from others, we are able also to distinguish the relations between them and other objects. The distinguishing of the relations between objects is attainable only through the detection and discrimination of their attributes, and the consequent distribution of them in thought into classes. Perfect distinctness of thinking, in this appropriated signification of the phrase, is evidently not attainable in regard to any object of human knowledge: and, as far as there are relations of an object which we cannot distinguish from others, our idea is indistinct. Distinctness, therefore, is relative,—relative to the purpose of our thinking: and the practical question in a given case is, whether, with reference to the purpose, the distinctness is adequate or inadequate.

Accordingly, obscure thinking cannot yield terms of any kind that shall be useable with intelligence. Clear thinking may be represented either by singular or by common terms. Thinking which, besides being clear, is also distinct, can be signified by common terms only.

52. Having gained a clear idea of a class of objects denoted by a common term, we next seek to make that idea distinct, by evolving such relations to other objects as are implied in the notion of the class. Using our common term as subject, we attain a step in distinctness by each other common term which we are able to affirm as predicate of it. Such affirmation we can justify to ourselves through, but only through, a preconceived ordination, in which our common term is one of the members; and we have the affirmation when we place our common term either in the extension or in the comprehension of another common term. Further, when we place a term Y in either whole of another term, as either X or Z, we do so really for the purpose of evolving an element in the other whole of Y. The interlacement and inversion of the two wholes are inextricable and constant.

On the one hand, looking upwards in the scale of extension, we place our given class in a higher class, which, besides our given objects, contains also others having certain of the attributes of ours. Thus we affirm, in extension, that "All Y's are X's:" that "All animals are beings organized;" that all animals are contained in the class of organized beings. In so predicating, we make our idea of

appropriated meaning of those terms, as explained immediately, increase of "distinctness" appears to be what is gained in both ways. (But see Mansel, *Prolegomena Logica*, pp. 186-194.)

¹ The distinction, currently applied in the German schools, and lately beginning to be familiar among us, is Leibnitz's. It is laid down in his *Meditationes de Cognitione, Veritate, et Ideis*, and illustrated in his *Nouveaux Essais*, book ii., chap. 22; (*Opera*, ed. Erdmann, pp. 79-81, 288-292).

Doctrine of "animals" more distinct, by evolving the fact that animals possess the attribute of organization; that is, that "organization" is a part of the comprehension of "animal."

On the other hand, looking downwards in the scale of extension, we place our given class in a lower class, which contains fewer than all the objects of our class, because all the objects it does contain possess attributes not possessed by all our objects. Thus we affirm, in comprehension, that "Some Y's are Z's;" that "Some animals are men;" that some animals possess the attribute humanity. In so predicating, we make our idea of "animals" more distinct, by evolving the fact that some animals belong to the class man; that is, that "man" is a part of the extension of "animal."

Thus we have made our idea of a given term more distinct by two steps in opposite directions, through our possession of two other terms, the one higher than it in extension, the other lower. By placing Y in the extension of X, we enable ourselves to infer that X is in the comprehension of Y. By placing Y in the comprehension of Z, we enable ourselves to infer that Z is in the extension of Y.

Hypothetical growth of a definition and a division: the first step.

53. Suppose our whole knowledge of a common term Y, or of the objects denotable by it, to be present to the mind in the implicative shape of a series of terms, ordinated in extension; suppose that the series stretches from our common term both ways, upwards and downwards; and suppose, also, that it embraces no co-ordinate terms. The knowledge thus implied would be completely explicated by two successive affirmations. In each of these Y would be the subject: while the predicates would be the other terms of the series; the higher terms in the one affirmation, the lower in the other.

Let our series be this: "Organized beings—Animals—Men—Europeans—Scotsmen;" and let it be understood as an implicit expression of the complex idea signified by the term "*Men*."

In extension we may affirm, that "All men are animals and beings organized." Analytically taken, the assertion is this: "All men—are—some of those beings who are both animals and beings organized; or, "All men—are—some of those beings who possess the attributes animal life and organization." We have evolved two attributes which are in the comprehension of the term "man." Conversion makes the assertion a predication in comprehension: "Some of those beings who possess the attributes animal life and organization—are—all men." Our proposition is, in fact, a definition. It is, doubtless, an unsatisfactory and imperfect definition; and it betrays its faultiness by the non-distribution of one of its terms. But it is the only definition of "man" which our data allow us to form.

In comprehension, again, we may affirm, that "Some men are Europeans and Scotsmen." Analyzing the assertion, we have it thus: "Some men—are—all those beings who are both Europeans and Scotsmen;" or, "Some men—are—all those beings who, while they are in the class Europeans, constitute the class Scotsmen." We have evolved two classes, both of which are in the extension of the term "man." Conversion makes the assertion a predication in extension: "All those beings who are both Europeans and Scotsmen—are—some men." Our proposition is, in fact, a logical division. It is an imperfect division; and the non-distribution of one of the terms brings the imperfection to the surface. But it is the only division of "man" that can be developed from the data.

The definition and division we have formed are both of them imperfect: they want something they should have. But they may be said to be also redundant: they have something which, in most cases, they need not have. It is well to clear away the redundancy before scrutinizing the grounds of the incompleteness.

54. In attempting to frame either a definition or a division, we pay especial attention to two points of limitation. We aim at simplifying both thought and expression. Entertaining this design, we directly explicate those elements only of the idea, those relations only of the objects, which we foresee to be available in the subsequent progress of our reasoning. We leave undeveloped all elements or relations, which do not seem to have a prospective bearing; and we do so with safety, if the elements we neglect cannot emerge as we proceed in thought.

Perhaps we are well acquainted with the objects compared; while, also, our field of reasoning is not to spread beyond a few of their relations. In such a case we shall usually, even if we have antecedently thought out a long series of ordinated terms, neglect all except one of the higher terms, or all except one of the lower. If we should wish to define the term "man," from materials supplied by the ordination lately given, either the attribute of animal life or that of organization would oftenest be the only one of the two in which we are directly interested. If the case be so, we shall content ourselves with asserting, either that "Man is an animal," or that "Man is an organized being." So, if we wish to divide the term "man," we shall almost always assert only, either that "Some men are Europeans," or that "Some men are Scotsmen;" we shall not make both assertions. In a word, we evolve only one step in the ordination; whether that be the first step either way from our given term, or a step more distant.

There are, however, three cases at least, all of them not only supposable, but actual, in which it becomes necessary to evolve more steps than one, or even a considerable number. In the first case, either definition or division is attempted, when our knowledge of the objects is so narrow as to yield only a series of terms, which do not justify a sufficient number of exclusions (co-ordinates being here the terms that will be wanting). Secondly, either may be attempted, when language does not furnish words clearly implicative of suppressed steps in a series. Lastly, either may be attempted, when, though knowledge and language should both be sufficient for their work, our definition or our division is designed to be the foundation of a very wide and complicated system of knowledge. Scientific definitions and divisions, for example, especially the former, are often necessarily complex, setting forth several steps from an ordinated series of terms; and the desire to simplify and abridge the series is one of the strongest of those many reasons, which justify the invention of technical names.

55. The incompleteness of our examples of growing definition and division is a point lying much deeper than their at first redundancy. The reason of it, and the remedy, require to be considered with especial closeness in their bearing on the definition.

(1.) It is, as we have seen, necessary to a definition, that the term to be defined be placed in the extension of at least one other term. The objects denoted by the given term are thus included in a class, all the objects of which have a certain attribute; and this attribute is a mark of the given term, that is, a part of its comprehension.

In defining "man" from our series of terms, we must be able to predicate of it one of the superordinates in extension. We must at least be able to affirm, that "All men are animals;" and, for most definitions of the term, the wider affirmation, of "organized beings," will not be required.

(2.) Such a placing of the term in the extension of a superordinate, or even in that of several or many such, is not sufficient. By the hypothesis involved in ordination, there may be, and we know that in fact there always are, other terms, thinkable as co-ordinates of the given term. Of each of these co-ordinates the superordinate might be affirmed, as well as of the term to be defined. Therefore

Doctrine of propositions.

Definition and division at their second step of growth.

Doctrine of it is that, in our embryo definition, the superordinate term was undistributed: "All men—are—some animals;" there may be, and we know there are, other animals besides men.¹

(3.) What is sought, in addition to the superordinate, is, the means of distinguishing the given term from its co-ordinates. But distinction is negation. Therefore, besides affirming the superordinate, we must be able to deny all the co-ordinates. We must have, for incorporation, as a sub-ordinate element of our predicate, the import of a proposition of exclusion.

Suppose we know only that there are animals which are not men. The two co-ordinate terms "men," and "not-men" (animals being implied), constitute together the immediate extension of the term "animal;" and either of the two is, by the law of predication for co-ordinates, deniable of the other. This filling up of the class "animal" by the two subclasses, would enable us to frame a definition, which could hardly ever be useful, but which might sometimes be the only one attainable, while in form it would be quite regular, though very awkward: "All men—are—all animals that are not Not-men."

But we may know something more: we may know names denoting all the co-ordinates of "man:" we may know that there are (according to a loose zoology, more generally understood than more scientific ones) five kinds of animals besides man. These five, taken together, become equivalent to our "animals that are not-men." Our definition will now stand thus: "All men—are—all animals that are not beasts, nor birds, nor fishes, nor reptiles, nor insects." But the definition, so altered, is still of little use. It cannot become extensively available, so long as it is merely negative of the co-ordinates.

(4.) The definition may be perfected when we have discovered some attribute, which is either possessed by the class denoted by the term to be defined, and wanting to all its co-ordinates, or possessed by all the latter, and wanting to the former. Such an attribute (in the former case), or its contradictory, denoting the want of it (in the latter), is a mark of the given term. The co-ordinates, as not possessing the mark, are thinkable as all of them contained in the contradictory of the given term, and may, therefore, be denied of it. The legitimacy of this denial is implied, when we affirm that the attribute, or its contradictory, is a mark of the term to be defined.

The schoolmen were wont to assign "rationality" as an attribute which is a mark of man, because alleged to be wanting to all other animals. "Not-rationality," the want of rationality, its contradictory, would thus be the attribute possessed by the co-ordinates, and wanting to man. Accepting this mark, we should now be able to express our definition in either of two shapes. Negatively, we should say, "All men—are—all animals that are not non-rational;" and here "non-rational" takes the place, and is an exact equivalent, of our "not-men," and "neither beasts nor" other animals. Affirmatively, we should say, with exact identity of meaning: "All men—are—all animals that are rational."

It has been necessary, for the completion of the analysis,

¹ Students of the science, who may be disposed to bestow close attention on the theory of the Definition, may be invited to scrutinize for themselves the point which it is here attempted to bring out; namely, the function of co-ordination in the process of defining—the fact that one of the elements of the definition (it is that which the schools call the Specific Difference) is equivalent to a negation of the co-ordinates of the definitum. The embryo of this doctrine lurks in several systems of logic. But it does not seem to have anywhere come fairly above ground. Indeed, in some of the best of the German books, the difficulty (which has not been overlooked) of determining the relations between the definitum and the specific difference has proved to be insurmountable. Twisten, the most clearly systematic among the formal logicians of Germany, has (strange to say) expressly denied the applicability of co-ordinates as elements of a definition. (*Die Logik*, p. 211.)

to bring out the negative form of the definition. But the affirmative form is always, and rightly, preferred when it is attainable: the distinctive mark is more readily useable in this shape. Besides this, it does more frequently offer itself in this shape than in the negative. It is usually easier to discover, by observation, an attribute possessed by one class and wanting in others, than to discover an attribute which, while wanting in one class, can peremptorily be asserted to be universal in each of several others.

(5.) In respect of formation, as it thus appears, a definition grows out of two several assertions. These are, both of them, in extension, though in different degrees; and, further, they are opposed in quality. It has been affirmed that the definitum (the term defined), is identical with a part of the extension of a superordinate term: it has been denied that the definitum is identical with the extension of any co-ordinate terms.

(6.) In result, a definition is, in the form it commonly wears, a predication in extension; because the term given to be defined tends naturally to preserve its place as subject. But, as its terms, being equivalents, are interchangeable, conversion throws it into comprehension. Which of the forms it may take, is a question utterly indifferent. For it is an affirmation that the *Definitum* and the *Definitio*, the subject and the predicate, are terms identical both in extension and in comprehension; that they are merely two several names for one and the same class of objects.

It is, however, the comprehension only that the definition evolves: the defined term being one of the two terms, the other term explicates those terms which constitute its comprehension. The proposition is an assertion that the comprehension of the term defined is constituted by certain attributes; that the comprehension of "man" is constituted by "animality" and "rationality." Looking to the other side, all that we are told is this: that the extension of "man" is constituted by all objects, whatever they may be, which possess both of those attributes.

56. The way having been found to the removal of incompleteness in a definition, similar dealing with a division is much facilitated.

Division at its third step of growth.

The term to be divided is the name of a class: it will be divided in one step, when we have affirmed of it the names of all the co-ordinate sub-classes which constitute, in one degree, the extension of that class. The divided class, and the aggregate of the sub-classes into which it is divided, are co-extensive. The objects which, when thought of in one group, are denoted by the one given term, are the same objects which, when thought of in several groups, are adequately denoted, all of them, by the enumeration of the terms we have evolved out of the given one. The subject and the predicate of a proposition enunciating the division, are but different names for one and the same aggregate of objects: therefore they are interchangeable; and the conversion of the proposition is free both ways.

So long as our terms were only the given term on the one side, and one, or some, of the terms subordinate in extension on the other, one of the terms (the term given) was necessarily undistributed. We had to say, before, "Some men—are—all Europeans;" or, "All Europeans—are—some men." But, in order to complete our division, we learn that the class "man," when we divide it on the principle of local habitation, may be loosely distributed into five sub-classes. At length, therefore, by uniting the names of all those sub-classes to form one of our terms, we gain a proposition in which both terms are distributed. We say, "All men—are—all Europeans, all Asiatics, all Africans, all Americans, all Australasians;" or, "All Europeans, all Asiatics, all Africans, all Americans, all Australasians—are—all men."

These forms of expression, however, are awkward, and may

Doctrine of
proposi-
tions.

be deceptive. If they are to be adopted, the "all" will be understood (naturally, and perhaps unavoidably), not distributively, but collectively. On this footing the terms are equivalent to singulars; and the propositions are unmanageable. But let our "all" be understood distributively: we are thus led to the alternative or disjunctive form of speech in the enumeration of the subordinate terms. "All men—are—all men who are either Europeans, or Asiatics, or Africans, or Americans, or Australasians;" or, "Every several man—is—every several man who is either a European, or an Asiatic, or an African, or an American, or an Australasian:" and so when the terms are reversed.

Now, it is in this alternative shape, though without signature of the predicate, that we do always, in ordinary thought and speech, express a division. We say: "Every man is either a European, an Asiatic, an African, an American, or an Australasian;" or, "Every one who is either a European, an Asiatic, an African, an American, or an Australasian, is a man." This fact is a guide-post, pointing out the road by which we reach the application of divisions in reasoning.

Divisions may, of course, be carried down in more steps than one; in as many steps, indeed, as our presupposed ordination allows, and the purpose of the division makes to be desirable. But, cumbrous even when embracing one step only, they become, when stretched farther, almost inexpressible in the shape of explicit propositions. In such cases, and sometimes in the simpler ones, they are usually left unexplicated. Scientific writers, especially in the sciences of Classification (where both definitions and divisions are often exceedingly complex), content themselves with exhibiting the ordained series of terms in a tabular shape: and from this series special propositions are extricable when called for.

A division, then, is a proposition which, when the term to be divided is taken in its natural function as subject, is a predication in comprehension, but which is readily transformable into a predication in extension. It is the extension only of the divided term that is evolved. The divided term being one of the terms, the other explicates the terms which constitute its extension. The proposition is an assertion that the extension of the divided term is constituted by certain sub-classes; that the extension of "man" is constituted by all the objects of the five named classes. On the other side, we are told only this: that the comprehension of "man" is constituted by all the attributes, whatever they may be, which are possessed by all those objects.

Division
compared
with defini-
tion

57. The theory of division is not yet wholly before us. It is completed when we contrast the process with definition. The result rests, as closely as that of definition, on preformed propositions. The character of these is unchanged; but their relative prominence is reversed.

(1.) There is, in division, a mutual negation of two co-ordinates; and this negation has for its basis the necessary inconsistency between a term and its contradictory.

Of the evolved terms constituting the extension of the given term, we fix our attention on some one: if we take more than one, these are thought as one. We must be able to think of this one term, and of all the others taken together, as being contradictories of each other. If "European" is the term we attend to, the other four are for us equivalent to "Not-European." Our implied negation is, that Europeans on the one side, and all its co-ordinates on the other, are mutually exclusive; that Europeans are not any persons who are either Asiatics or persons of any of the other classes. But this is on the assumption that the same negation might be made through the contradictories; that we should be expressing the same denial, although with a narrower assumed knowledge, by saying, that "Europeans are not Non-Europeans."

Each of the co-ordinates must thus, in its turn, be thought as deniable of all the rest, or as having all these as constituting its contradictory. If it were not so, there would be a manifest confusion of identities.

Doctrine of
proposi-
tions.

(2.) The negation of co-ordinates, which is left as implied in the definition, is, in the division, the element which is explicitly set forth. The thorough-going exclusion of the evolved terms from each other, is expressly signified by the alternative words "either" and "or."

(3.) There is affirmation with two terms, a super-ordinate and a subordinate. And, in division, though not in definition, the affirmation is at least double, and may be regarded as being often manifold.

There is presupposed the inclusion of all the evolved terms in the extension of the term given to be divided: "Europeans are men;" "Asiatics are men:" and so on. This is self-evident as to all the positive terms. Each of our evolved terms, then is, virtually, "Men who are Europeans, Asiatics," and so on. But, though we were to pass only from "Europeans" to its contradictory, there would be the same implication: and this view brings out the point with especial distinctness. We must here have the same inclusion: "All Non-Europeans are men:" the contradictory term is, virtually, "men who are Non-Europeans." If the contradictory of "Europeans" were taken without this limitation, it must denote all thinkable objects besides Europeans: it would cease to be truly co-ordinate with Europeans; and the foundation of the division would be overthrown.

In a word, the contradiction, and consequent exclusion, which are thought in the process of dividing, are a contradiction and exclusion not absolute or pure, but only within the sphere or extension of the given term. The objects thought as constituting that sphere, are posited or assumed in the whole process: they constitute what has aptly (though not with this reference) been called the "Universe" of all the propositions which the division either expresses or implies.¹ The terms contradictory of each other, whether explicitly or virtually, are not pure contradictories, but only contradictories within the given sphere.

(4.) The affirmation of inclusion, which, in the definition, is the element explicitly set forth, is, in the division, the element which is left as implied. It lies, indeed, so deeply hidden, that logicians have sometimes overlooked it: a decisive instance is described in the next section.

58. Every division, however complex, is thus reducible, at each of its steps, to a Dichotomy; that is, to the division of a class into two sub-classes opposed to each other by contradiction. The term X, if divisible positively by several terms, of which Y is one, is divisible also by the terms Y and Not-Y. Division by dichotomy.

Dichotomy is not only the normal form of division, the form in which the primary principle appears most clearly. It is also a form of division which has practical uses, and which has, by some thinkers, been adopted as the explicit basis of all classification.² Requiring no positive assumption as to any of the co-ordinates but one, and regarding all the others as merely contradictory of the first, it has been vaunted as the ideal of a process fulfilling the requirements of a pure or *a priori* logic. In confutation of this claim it has been alleged, that the negative co-ordinate is not a pure contradictory of the positive: that when the class X is supposed to be divided into the sub-classes Y and Not-Y, the second sub-class is really "Those X's which are Not-Y's."

¹ De Morgan, *Formal Logic*, p. 38.

² It is enough to instance Peter Ramus among older thinkers, Jeremy Bentham among moderns. The latter name is certainly a symptom that dichotomy cannot be without its practical uses. As to the theoretical difficulties attending it, see especially Trendelenburg.

Doctrine of
proposi-
tions.

The correct view seems to be that, of which an explanation was attempted in the last section. It is true that both of the co-ordinate terms are positively limited, each of them being in thought included in the superordinate: the members which really divide the class X are these: "The X's which are Y's;" "The X's which are Not-Y's." The contradiction of terms which is gained, a formal and direct contradiction within the sphere of the term given to be divided, is the only contradiction which the case admits; and, within the sphere thought of, it is a pure contradiction.

Even so considered, the facts refute the claim of dichotomy to being an application of the laws of pure thought, without any consideration of matter. But this, as we have seen, is a claim that cannot validly be urged in behalf of any logical law whatever. Least of all is it tenable in regard to laws which, assuming concepts and common terms as given, must presuppose some of the widest and most perplexing of the objective relations, under which only actual knowledge is possible.¹

The five
predi-
cables.

59. In all those logical systems which found their theory of definition and division on the scholastic and Aristotelian opinions, that theory rests, for both processes, on the scheme of the Predicables. The doctrine of the predicables is, in some of its parts, clear and valuable: in others it is difficult alike of explanation and of application. So much of it must here be described, as shall exhibit the bearing of the analysis above proposed on the common rules of definition and division.

Predicables are terms affirmable, as predicates, of other terms. Further, the identical affirmation of singulars being neglected, all predicables are said to be common terms. All the common terms which are affirmatively predicable of others, must import, relatively to the subject of the proposition, one or another of five things. The Predicables are five:—Genus, Species, Difference, Property, and Accident.

(1.) Of any term given as subject, we may affirm, as predicate, its genus. The genus is the widest class in which, according to the view supposed in a given process of thought, the subject can be held as included.

(2.) Of the subject we may affirm its species. The species is any one of several narrower classes, actual or thinkable, which together make up the genus or widest class. In it, as in the genus, the subject is presupposed to be included.

(3.) Of the subject we may affirm a difference. The idea attached to this term has been defined and limited very variously. It receives, probably, the fullest justice when we say, that a difference is an attribute possessed by a whole class, and by that class alone,—that it is an attribute possessed by all the objects of a class, and not by any other objects. It is an attribute universal and peculiar to the objects of a class. Since there are two classes, a more ex-

¹ The dichotomous division has its chief value in the earlier progress of a science: there it is an admirable and often a decisive test. The principle of it, and often its form, enter widely into those processes of applied logic which are described as processes or methods of induction. But its direct use goes no further than allowing us to throw aside, by repeated exclusions, classes of objects which observation has shown to be alien from the purpose of our inquiry. It thus narrows, by successive steps, the ground over which our new observations have to be carried. We commence our scrutiny of the class X, by distributing it into two sub-classes. The one of these is Y, of whose laws or attributes we know something: the other is Not-Y, in regard to which, as yet, we may know nothing. If Y does not satisfy the conditions of our problem, both Y and the containing class X are dismissed from our thoughts. Our field lies now in the class Not-Y; and it may similarly yield Z and Not-Z, to be dealt with as before. This is one of the uses of the process; but its variability, as a groundwork of exclusion, is very great.

tensive and a less extensive (the genus and the species), Doctrine of difference may, correspondingly, be of two several kinds. A generic difference is an attribute universal and peculiar to a genus, and thus distinguishing the genus from all other possible genera: a specific difference is related in the same way to a species. The former is of little or no use.

(4.) Of the subject we may affirm a property. This term, which has been described as variously as the difference, may be explained thus. A property is an attribute possessed by a whole class, but not by that class alone: it is an attribute possessed by all the objects of a class, but possessed also by other objects; it is an attribute universal but not peculiar to the objects of a class. Property, like difference, might be either generic or specific: but property is plainly useless both for definition and for division, unless in the way of preparatory exclusion; therefore the distinction has not been worked out. When the name is applied at all, property seems always to be held specific.

(5.) Of the subject we may affirm an accident. An accident may be said to be an attribute which is possessed by some of the objects of a class, but is not thought of as possessed by all of them. As we are here touching on individuality, accident is always held as specific; the species being, in this scheme, the lowest class, between which and the individual objects no class is thought as intervening. Accidents are further said to be either separable or inseparable. An inseparable accident is an attribute which we cannot, a separable accident is an attribute which we can, think of the subject as not possessing.¹

60. It has often been made a ground of objection to the predicables, that the criteria by which they are distinguished from each other presuppose an objective certainty, an insight into the true nature of the objects compared, which is alike impossible of attainment, and beyond the range of logical scrutiny. The charge is good against not a few of the explanations that have been given, especially of the last three. But the essential character of the scheme is quite in accordance with the fact, that all classification is merely relative, that the placing of objects in classes is nothing more than an operation of thought. The scheme, likewise, is easily useable, within proper logical bounds, as a means of explicating the results of a classification which has been thought out, whether in consonance, or in repugnance, to the real character of the objects.

This much having been premised, we shall readily perceive the bearings of the scheme on definition and division.

(1.) It is observable, in the first place, that the scheme supposes an ordination, of classes or common terms, embracing only two steps, a superordinate and a subordinate,—the genus and the species. It is admitted that more are frequently required; and the terminology has been tortured into elasticity, to make it answer the demand as fully as possible. Genus and species, we are warned, are relative terms: every class is a species in reference to a more extensive class; every class is a genus in reference to a class less extensive. We are allowed to speak of a *summum genus*, and of subaltern genera contained in it; and we receive from some quarters a license to introduce sub-species.

(2.) Still, the range of terminology is palpably inadequate to many scientific purposes. It is especially so for those sciences, which have to distribute and redistribute, by inclusions and exclusions multifariously repeated, a vast number

¹ In regard, here, to difference and property, and also in the next section, obligations are due to an *Examination of some Passages in Dr Whately's Logic*, by George Cornewall Lewis, 1829. Other recent writers, also, in England, have speculated much and acutely on the doctrine of the predicables. They are scrutinized very closely in Mansel's edition of *Aldrich*.

the predi-
cables in
definition
and divi-
sion.

Doctrine of inference.

PART III.—THE DOCTRINE OF INFERENCE.

Doctrine of inference.

CHAPTER I.

The Character and Kinds of Inference.

The character of inference.

62. The scholastic logicians described the science as analyzing the products of three mental operations, specifically different: Apprehension, Judgment, and Reasoning. There is a psychological difference between the first two of these, the difference between thought unevolved and thought evolved: and the two kinds of facts yield products differing in form. It is now allowed, generally and rightly, that there is no such difference between judgment and reasoning: the latter operation is constituted by repetitions of the former. Whether we judge or reason, we are alike explicating, in forms yielding propositions, implied relations of given ideas and objects.¹

The forms, however, in which the data may be presented, differ so far as to modify secondarily the forms of explication, and especially by causing diversities in the degree of complexity. It is, therefore, desirable that the most prominent of the explicative forms should be studied separately. There is thus a practical reason for logically treating judgment and predication apart from reasoning or inference, and also for considering severally the leading varieties in the forms of inference.

The only formal difference which can enable us to distinguish, consistently and firmly, between predication and inference, is that which arises out of the distinction between apprehension and judgment. A process in which a proposition is evolved directly from given terms, is a mere predication. Every process in which a proposition is evolved directly from one or more given propositions, must be considered as an inference.

The kinds of inference; immediate and mediate.

63. Every inference contains, in expression as in thought, two parts, that which is given and that which is sought,—the Antecedent and the Consequent. The immediate consequent must be one proposition only. But the antecedent may be either simple or complex: it may be constituted by one proposition only, or by more propositions than one.

An inference, whose antecedent is constituted by one proposition, is an Immediate Inference. There is explicated, in the antecedent, a relation between two terms: there is explicated, in the consequent, between the same two terms, another relation which had been implied in the given one.

An inference, whose antecedent is constituted by more propositions than one, is a Mediate Inference. The simplest case, that in which the antecedent propositions are two, is

¹ "According to these definitions [Locke's], supposing the equality of two lines A and B to be perceived immediately in consequence of their coincidence, the judgment of the mind is intuitive: supposing A to coincide with B, and B with C, the relation between A and C is perceived by reasoning. This is certainly not agreeable to common language. The truth of mathematical axioms has always been supposed to be intuitively obvious: and the first of these affirms, that, if A be equal to B, and B to C, A and C are equal. Admitting, however, Locke's definition to be just, it might easily be shown, that the faculty which perceives the relation between A and C, is the same with the faculty which perceives the relation between A and B and between B and C. When the relation of equality between A and B has once been perceived, A and B become different names for the same thing. That the power of reasoning (or, as it has been sometimes called, the Discursive Faculty), is implied in the powers of intuition and memory, appears also from an examination of the structure of syllogisms. It is impossible to conceive an understanding so formed, as to perceive the truth of the major and minor propositions, and not to perceive the truth of the conclusion." (Dugald Stewart, *Outlines*, part i., sect. 9.)

the Syllogism. The syllogism is the norm of all inferences whose antecedent is more complex; and all such inferences may, by those who think it worth while, be resolved into a series of syllogisms.¹

By syllogistic inference we seek to explicate, in the consequent or conclusion, a relation between two terms. In the premises or antecedent propositions, there is not explicated any relation between those two terms; but in each of them there is explicated a relation between one of the two terms and a third. This third, or mediating term, stands so related to the other two, that the explicated relations between them and it imply a relation between the two themselves; and this is the relation which is explicated in the consequent.

In every process of inference, the consequent is the explicit assertion of an identity or non-identity between its two terms; which identity or non-identity was implied in the antecedent. When the predications are through common terms, the Quality of the consequent, as affirmative or negative, is determined, in the last resort, by reference to the ordination of the terms. The Quantity of each term of the consequent is limited by the quantity of each of the terms of the antecedent; and this quantity is traceable specially to the extension of each of those terms.

CHAPTER II.

Immediate Categorical Inference.

64. All processes of immediate inference, whose validity is determinable by rules purely formal, may be embraced under four kinds. We infer immediately, either by Contraposition, by Subalternation, by Opposition (proper), or by Conversion.

These several kinds of processes stand towards each other in different relations of likeness and unlikeness. They may advantageously be compared from two different points of view.

(1.) The terms being common terms, each proposition, both antecedent and consequent, must be a predication of the subject, either in (or out of) the extension of the predicate, or in (or out of) its comprehension. If the matter of the assertions is not known, the data are not wide enough to indicate in which of the wholes the predication is. But certain points are ascertainable without interpretation of the terms.

In their relation to the two wholes, the first three processes are unlike the fourth. In inference by Contraposition, Subalternation, and Opposition, the antecedent and the consequent predicate in the same whole: both predicate

The modes of immediate inference; and their several characters.

¹ By the older logicians, and by those of this country till recently, the name of Inference, Reasoning, Discourse (Shakspeare's "*discourse of reason*"), was limited to the syllogism and processes yet more complex. The extension of it, so as to embrace the processes here called immediate inferences, seems to have been first made by some of the German logicians after Wolf: it was adopted by Kant, who has been followed in this point by all his countrymen. By more than one of these, however, it has been shown, that his distinction of the two kinds, as being respectively inferences of the understanding, and inferences of the reason, is not so much as consistent with his own psychology.

The secondary difference between inference and simple predication being recognized, the old limitation of the former name not only is incorrect, but tends to disguise from us the real character of inferences which are immediate. Any valid reason for refusing the name to processes of this sort, would tell with equal force against the syllogism.

Doctrine of inference. either in extension or in comprehension. In inference by Conversion, the antecedent being a predication in one whole, the consequent is a predication in the other: the process consists, as has already been alleged, in the transference of predication from extension into comprehension, or contrariwise.

(2.) The processes fall into other groups, when we consider the relation of truth or falsehood between antecedent and consequent. In this respect the first, second, and fourth kinds are unlike the third.

Contraposition, Subalternation, and Conversion, yield consequents, whose truth or falsehood, when it is determinable, agrees with the truth or falsehood of the antecedent. If the antecedent is admitted as true, the consequent must be admitted: if the antecedent is denied, the consequent must be denied. Opposition (proper) yields consequents, whose truth or falsehood, when it is determinable, is opposed to the truth or falsehood of the antecedent. If the antecedent is admitted, the consequent must be denied: if the antecedent is denied, the consequent must be admitted.¹

Inference by contraposition.

65. By Contraposition we gain a consequent, which must be admitted if the antecedent is admitted, and denied if the antecedent is denied.

We shall call the antecedent the *Contraponend*, the consequent the *Contraposita*.²

The process consists in transforming, through the law of non-contradiction, a given Affirmative into a Negative, which is accepted as equivalent or equipollent, or a given Negative into an equivalent Affirmative. In both cases the method is, to substitute for the predicate the term which is its contradictory, and then, as a necessary consequence, to change the character of the copula.³ The principle is self-evident: what is done is to apply one of the logical axioms in its simplest shape. If, of a given term, we can affirm another, we must be entitled, of the first term, to deny a term which is contradictory of that other: if, of a given term, we can deny another, we must be entitled, of the first term, to affirm the contradictory of that other. If the X's are contained in the sphere of the Y's, they must be excluded from the whole of the sphere of the objects which are Not-Y's: if the X's are excluded from the sphere of the Y's, they must be contained in the sphere of the objects which are Not-Y's.

The affirmative becomes a negative, when, instead of

¹ Those who refuse to these processes the name of Inference, rest on this allegation; that, since the terms of the antecedent and those of the consequent are the same, the two propositions must merely express the same thought in two different forms.—Of Conversion this is plainly not true. It is far from being a matter of indifference to the real character of a judgment, which of its terms is taken as subject, and which as predicate: so much is evident without reference to the wholes of the concept, the examination of which founds more deeply the reasons of the difference. As to Opposition proper, the case is perhaps still clearer. We cannot be said to express the same judgment, in enunciating one proposition which is true, and another which, however closely related to the former, must be false. In respect to Subalternation, the question is narrower, lying merely between the "all" and the "some" of the subject. But here, likewise, the doubt falls away, when we remember that, on the strict analysis which we are bound to aim at, that which is really either subject or predicate, is not a common term which is distributable, but that term peremptorily fixed as being either distributed or undistributed. "All X's," and "some X's," are the names of two several sets of objects. If there be any of the immediate inferences whose claim to the inferential character is reasonably doubtful, it is Contraposition, to which we now pass.

² The caution must be given that, in several of our English books of logic, the name of contraposition is given, not to this process, but to a twofold one, in which there really take place, first, contraposition; secondly, conversion of the contraposita. We shall speak of this complex process as Conversion through Contraposition.

³ The subject, as denoting the notion or object given to be determined, must remain unchanged. It cannot be displaced by its contradictory, until it has first, by conversion, become predicate.

affirming the predicate, we deny its contradictory. Thus, Doctrine of inference. "All X's are some Y's" (A), becomes "The X's are not any Not-Y's" (E). The negative becomes affirmative, when, instead of denying the predicate, we affirm its contradictory. Thus, "Some X's are not any Y's" (O), becomes "Some X's are some Not-Y's" (I). There is in this way a possibility of contraposition, in both directions, between A and E, between I and O.¹

¹ This is a process which serves so many uses in the analysis of the syllogism, that it demands particular notice. The doubt, however, as to its claim to being held a genuine inference, is raised at once by some of the phrases which have just been applied to it. Two propositions, strictly and absolutely equivalent, cannot but be mere varieties of expression for one and the same judgment. But, on the other hand, it is questionable whether any two propositions do stand in such a relation. The minute anatomy of thought would exhibit fine differences in the character of the acts, even between cases of equivalence through synonymous terms, or through other variations not logically cognizable. One judgment is not in all points necessarily identical with another, though the two compare the same objects: the identity fails, as soon as there creeps in the slightest discrepancy between the relations in which the objects are thought.

It is fairly maintainable, that the contraponend and the contraposita are not absolutely equivalent,—that each of them brings out distinctly an element of thought which is merely implied in the other. I have, it may indeed be said, the same thought, a thought constituted by the very same factors, when I place X somewhere or other in the positive and limited sphere of the Y's, and when I exclude it from all points of the negative and undetermined sphere of the Not-Y's. Thus much may be admitted, that the two thoughts grasp one and the same relation of the objects. But they apprehend it from two opposite points of view. Subjectively or psychologically, it is not the same act of thought that places an object in one sphere and out of another. Objectively, again, or with reference to the products of the acts, the reality of a difference is made probable, if not absolutely certain, when we attempt using the one proposition or the other, alternatively, as a premise in a syllogism. Each of the two places the terms in a certain relation, not yielded by the other, to the other terms of the argument. Sometimes, therefore, the one proposition enables us to construct a good argument, while the other would generate a bad one: at other times the argument admits only one fixed form, if the one proposition is adopted, but is made flexible through the substitution of the other.

The question, as to the true relation between the contraponend and the contraposita, was pressed on modern logicians by Kant's "Categories of the Understanding." He recognized, in respect of quality, not only the affirmative judgment (X—is—Y), and the negative (X—is not—Y); but also the limitative or infinite (X—is—Not-Y). The negatively-determined term, (as "not-man"), was admitted by Aristotle (*De Enunciatione, passim*): and from his name for it, *ἐναντιόλογος*, Boethius, and after him the schoolmen, called it (too widely) an "infinite term."

The old writers, moreover, acknowledged the infinite term as a *datum*, not for the predicate only, but also for the *subject*. When such a term does become the subject, the proposition has a peculiar character: it represents the explicit assertion of the ordinary "exceptives." "All things except the X's are Y's," gives, directly, "All not-X's are Y's."

It is curious to mark those ancient forms re-appearing, as data, in two recent systems.

1. Exceptive propositions give the foundation to Dr Boole's ingenious method of resolving (as others have attempted to resolve otherwise) all assertion into affirmation. His formula, "Y = X — Z," is interpretable as "The Y's—are—those X's which are not Z's." If, then, it is presupposed (as his notation postulates), that X is a genus containing the two species Y and Z, the assertion may take this form: "The Y's—are—Not-Z's," which is equivalent to denying a term of its co-ordinate.

2. The infinite term, again, yields the characteristic forms to the scheme of predication worked out by Professor De Morgan, through the terms which he inconveniently calls *contraries* (i.e., contradictories in the received nomenclature, as X and Not-X). Admitting "infinities," both as subjects and as predicates, he gains, as data for inference, eight "standard varieties of assertion," all treatable as A, E, I, O. The first four have, as subjects, positive terms (X): the last four have infinite subjects (not-X), and are virtually exceptives. Mr De Morgan is perfectly correct in deriving from each of his eight leading propositions two others, which thus make up his "contranumeral" forms of predication to twenty-four. Only, not distinguishing between conversion proper and conversion through

Doctrine of inference.

The kinds of opposition as commonly described.

66. In a large majority of logical systems, the name of Opposition is so applied, as to include Subalternation along with those other three relations to which, here, the name is limited. The three are these: Contrariety, Sub-contrariety, and Contradiction. The outline of the scheme, thus embracing all the four, may be used as an introduction to our separate examination of each.

No propositional forms but A, E, I, and O, being admitted, we can, with any two common terms, form four propositions only. Any two of these are said to be opposed to each other, in respect that they must differ either in quantity or in quality, or in both. The kinds of opposition thus appearing are four.

I. Propositions agreeing in quality, but differing in quantity, are called, in reference to each other, Subalterns. The universal is the Subalternant, the particular the Subalternate. Any two terms furnish two pairs of subalterns: A and I, E and O. The same laws govern both pairs: hence the relation has only one name.

II. Any two terms furnish also two pairs of propositions, agreeing in quantity, but differing in quality. The same laws do not govern both pairs: there are two relations, and hence two names. (1.) The two universals, A and E, are called Contraries. (2.) The two particulars, I and O, are called Subcontraries.

III. Propositions differing both in quantity and in quality are called Contradictories. Any two terms furnish two such pairs: A and O, E and I. There is here but one relation, and hence one name.

It is convenient to be thus enabled to look, at one glance, over all the possible combinations of the same two terms in assertions of inclusion and exclusion. The survey is usually facilitated, in the books, by the placing of the four symbolic letters in the angles of a square; the universals standing above and the particulars below, affirmatives on the left hand and negatives on the right. The relations or affections of each two propositions are then expressible by names placed in the sides of the square and in its diagonals.¹

But subalternation, yielding a consequent consistent with the antecedent, and the other relations, yielding consequents inconsistent with the antecedents, ought, as modes of inference, to be in some way distinguished from each other: and the name of opposition, aptly designating the last three, is hardly germane to the first.

leaps in argument, how they are traceable to the law of non-contradiction in one or more of its phases.

Doctrine of inference.

That which we seek to infer through opposition, is not a consequent consistent with the antecedent; not a consequent whose truth is involved in the truth, or its falsehood in the falsehood, of the antecedent. We seek a consequent inconsistent with the antecedent,—a consequent so related to the antecedent, that the truth of the latter shall involve the falsehood of the former, and the falsehood of the latter the truth of the former. In a word, our two propositions ought to be so related, that the laws of difference and excluded middle shall strike at them directly: they should be peremptorily and necessarily contradictory of each other; like the assertion, "X is Y," as compared with the assertion, "X is Not-Y."

But our subject, being a common term, may be either distributed or undistributed. This variability takes away the power of applying the two laws with the same simple universality, in which they govern propositions whose subjects are singulars. We have to take account of the identity and non-identity of classes and parts of classes, in all the modes of combination allowed by the four propositional forms. Having completed this inspection, we find that the contradiction between antecedent and consequent is not universally and formally guaranteed, unless when the two propositions have a maximum of difference, that is, unless when they differ both in quality and in quantity.

Accordingly, propositions thus related are called Contradictories by way of eminence. This kind of opposition leads always from affirmation to denial, and from denial to affirmation. Its rules, if first established, facilitate the proof of the rules governing the other two: Contrary opposition, which leads only from affirmation to denial; Subcontrary opposition, which leads only from denial to affirmation. Subalternation, which leads from affirmation to affirmation, or from denial to denial, will find its place afterwards, and complete our review of the relations connecting all propositions framed with the same subject and the same predicate.

68. That relation of propositions which, as yielding the only peremptory inconsistency, is emphatically called Contradiction, subsists between A and O, and between E and I. Of any two contradictory propositions, the one must be true and the other false. If the antecedent is admitted, the consequent must be denied: if the antecedent is denied, the consequent must be admitted.

Inference by contradictory opposition.

If we had to seek the contradictory of a given proposition, the problem would in effect be this: Given an assertion which is assumed to be either true or false; to find the narrowest assertion that would, in all possible instances, be inconsistent with the assumption.

The solution might be attained very easily through the laws which govern concepts. If we start from one of the universals as true, we assume that a whole class of objects have (or want) a certain attribute. We have thus a proposition either in A or in E. Evidently inconsistent with this would be the truth of the opposite universal (E or A), asserting that none of the objects have (or want) the attribute. But, if our first universal were assumed to be false, there would not be a necessary inconsistency between this assumption and the truth of the opposite universal. Though we have denied that all the objects have (or want) the attribute, we may still be able either to affirm, or to deny, that none of them have (or want) it. A thorough-going inconsistency, therefore, does not subsist between the universals. But there is such an inconsistency between a universal and the opposite particular. If it be true that all the objects have the attribute, it must be false that some of them have it not: if it be false that all the objects have it, it must be true that some of them have it not. The con-

The general character of inference by opposition proper.

67. The rules which determine the deducible truth or falsehood of the consequents gained through Opposition proper, are, for all the modes, so very obvious, that in most of our English treatises they are laid down without proof. But it is right to show, as briefly as may be, yet without

contraposition, he leaves in implication, in each of his deductions, one step, which, if supplied, would enable us to make all his inferences through the received rules. The omitted step is always a simple converse, from which his second consequent is deducible: for A and O it is the converse of the first consequent, for E and I the converse of the given antecedent. His first and eighth forms will illustrate both cases. 1. "All X's—are—Y's (A)=Contraposita: The X's—are not—Not-Y's (E)=Converses: The Not-Y's—are not—X's (E)=Contraposita: All Not-Y's—are—Not-X's (A)." 2. "Some Not-X's—are—Not-Y's (I)=Contraposita: Some Not X's—are not—Y's (O)=Converse of the I: Some Not-Y's—are—Not-X's (I)=Contraposita: Some Not-Y's—are not—X's (O)." All Mr De Morgan's eight contranominals are set forth by Boethius, in his *Introductio in Syllogismos Categoricos* (Opera, ed. 1570, p. 570, and elsewhere).

¹ We very often speak of assertions which we hold to be contradictory of each other, as being "diametrically opposed." The phrase is one of many which have migrated into common life from the scholastic cloisters. Substitute, for the square in whose angles the symbolic letters are now usually placed, a circle described about it. The diagonals of the square become *diameters* of the circle; and the pairs of contradictories stand at their extremities.

Doctrine of inference. tradition keeps its hold, whether we take, as our antecedent, the universal or the particular.

The leaning of affirmation and negation on identity and difference, and the necessary determination of thought towards the one or the other, may be brought to light as affecting these results, by the scrutiny of an example. The A and O will suffice: "All X's are some Y's" (A); "Some X's are not any Y's" (O).

The A is interpretable thus: "All the objects we call X—are identical with—some of the objects we call Y." The O is thus interpretable: "Some of the objects we call X—are non-identical with—all the objects we call Y."

In the first place, both of these assertions cannot be true. If we are entitled to affirm that all the objects X are the same objects which (with others) we call Y, we are much within the mark of safety, when we deny that some of the objects X are different objects from all those which we call Y. If we are entitled to affirm that some of the objects X are different objects from all those we call Y, we cannot possibly affirm also, that all the objects X are the same objects with some of those we call Y. If both assertions were true, there would be some X's which are identical with some Y's, yet non-identical with any Y's. We should, in effect, have affirmed, of the same subject, two contradictory predicates, Y and Not-Y.

On the other hand, both of the assertions cannot be false. Every thinkable object must be either Y or Not-Y. All the X's must either be some of the Y's, that is, identical with some of the objects in the sphere of Y; or they must be some of the Not-Y's, that is, some of the objects which are beyond that sphere.

In short, the one of the two assertions must be true, the other false. If the antecedent is given as true, we do, in other words, affirm the identity or non-identity of the objects designated by the terms: the consequent in this case involves a denial of that identity or non-identity. If the antecedent is given as false, we thus deny the identity or non-identity of the objects: and in this case the consequent involves an affirmation of that identity or non-identity.

Inference by contrary opposition.

69. The relation of Contrariety subsists between A and E. Of two contrary propositions, both cannot be true, but both may be false. If the antecedent is admitted, the consequent must be denied: but though the antecedent should be denied, the consequent is not therefore necessarily admitted.

(1.) The objects denoted by the term which is the subject are the same in the two propositions: "All the X's are Y's" (A); "The X's are not Y's" (E). If both were true, the two would coalesce into the one self-contradictory assertion, that the X's are both Y's and Not-Y's. Therefore, if either is true, the other must be false.

(2.) The assumption that A is false, amounts to this only: it is not true that all the objects of a class possess a certain attribute. But this leaves open either of two cases. First, it may be true that none of the objects of the class possess the attribute; that is, in other words, the E is true. Secondly, it may be true, that some of the objects do possess the attribute; that is, the I is true. But if the I is true, its contradictory must be false: and that contradictory is the E. The same proof would be applicable if we made the E our starting-point. Therefore, though one of the contraries is false, the other may be either false or true.

Inference by subcontrary opposition.

70. The relation of Subcontrariety subsists between I and O. Of two subcontrary propositions, both cannot be false, but both may be true. If the antecedent is denied, the consequent must be admitted: but though the antecedent should be admitted, the consequent is not therefore necessarily denied.

Our propositions are these: "Some X's are Y's" (I); "Some X's are not Y's" (O). Evidently there are here the

narrowest possible grounds of determination. The interpretation of the sign of quantitative limitation must be narrowly looked to. Doctrine of inference.

(1.) If the subject were quantitatively definite, it would signify, for each of the two propositions, "Certain X's;" "Those X's of which I now think." We should, on that supposition, have to demand an answer to the question; whether the X's thought of in the I are the same X's which are thought of in the O, or a different group of X's. If they are the same X's, the two propositions have the same subject, and are inconsistent. If the X's are different X's, the two propositions have different subjects; and an assertion in regard to the one subject determines nothing for an assertion in regard to the other. In effect, the term "Certain X's" is, as was noted in a preceding section, virtually equivalent to a common term distributed: the propositions are in substance universal, both of them, however, having, as subjects, terms which are ambiguous.

(2.) The subject being quantitatively indefinite, according to the orthodox logical interpretation of the sign, the case stands quite otherwise. The subject constitutes, of the objects denotable by the subject-term, a part which is in every direction indefinite: the part is some or other, a few or many, some and perhaps all, but without our being entitled positively to assume all.

First, then, let either of the propositions be assumed to be false. It is false that "Some X's are Y's" (I). But, by the law of excluded middle, all the X's, like all other thinkable things, must either be or not be Y's. Since, then, we have denied the assertion that some of them are Y's, we are driven on the assertion that some of them are not Y's. If the I is false, the O must be true. Starting from the O, we should reach the same result in regard to the I.—The demonstration may be made more exact, if we choose to anticipate the doctrine of subalternation. It is false that "Some X's are Y's" (I): therefore the contradictory of the I must be true; that is, it is true that "The X's (any) are not Y's" (E). Therefore the subalternate of the E must be true; that is, it is true that "Some of the X's are not Y's" (O).

Next, let either of the propositions be given as true. It is true that "Some X's are Y's" (I). Nothing is thus given as to the whole class X: for aught we know, all the X's may be Y's, or some of them may not be Y's. If "All the X's are Y's" (A), the O will be false, as being the contradictory of A: if "Some of the X's are not Y's," this is a direct assertion of the truth of the O.

71. The relation of Subalternation subsists between A and I, and between E and O. By subalternation we may by subinfer, either from whole to part, or from part to whole; from subalternant to subalternate, or from subalternate to subalternant.

In inference from Subalternant to Subalternate, if the antecedent is admitted, the consequent must be admitted. In inference from Subalternate to Subalternant, if the antecedent is denied, the consequent must be denied.

The peremptory consequences go no further. If the subalternant, as antecedent, is denied, the subalternate, as consequent, is not therefore, necessarily, either denied or admitted. If the subalternate, as antecedent, is admitted, the subalternant, as consequent, is not therefore, necessarily, either admitted or denied.

Let our propositions be the affirmatives: "All the X's are Y's" (A); "Some of the X's are Y's" (I). None of the preceding modes of inference lean, so openly as this, on the laws of predication through ordained terms. From these laws, indeed, the rules might be directly deduced. The "all X's" and "some X's," stand really in the relation of superordinate and subordinate. If the "some X's" had a name, as "all Z's," they would constitute a sub-class in

Doctrine of inference.
cluded in the class X; and, if the fact were so, all the cases both of affirmation and of denial would be regulated, directly, by the canons laid down for predication in extension. But subalternation stands on the hypothesis, that the class denoted by the subject has not been divided into sub-classes; and, on this footing, the rules may be justified by an immediate appeal to the elementary and universal principles of predication.

(1.) Of two subaltern propositions, both may be true, or both false.

Formally, we cannot determine which of the alternatives holds. If all the objects denotable by the subject-term are denotable also by the predicate-term, the A is true; and consequently the I also is true, the particular sign having its usual logical meaning. If none of the objects denotable by the subject-term are denotable by the predicate-term, we should contradict this assertion by affirming the predicate of the subject either in whole or in part: A and I would, both of them, be false. The negatives are readily determinable in the same way.

(2.) If the subalternant is true, the subalternate must be true: if the subalternant is false, the subalternate may be either false or true.

The first section of this rule follows from the character of the logical "some," of which we have just been reminded. This, the most obvious law of subalternation, is also that which is most widely applicable. But suppose A to be false: it is false that "All the X's are Y's." This assumption is consistent with the supposition that the E is true; and, if so, I, the contradictory of E, is false. It is consistent also with the supposition that the I is true: though it is not true that all the objects of a class have the attribute Y, it may be true that some of them have it.

(3.) If the subalternate is false, the subalternant must be false; if the subalternate is true, the subalternant may be either true or false.

On the one hand, suppose the subalternate I to be false. Then its contradictory E must be true; and A, the contrary of E, must be false. Or take it thus: By hypothesis, the I is false. Assume the A to be true; therefore all its subalternates are true, which is contradictory of the hypothesis: therefore, by the law of excluded middle, the A must be false.

On the other hand, suppose the subalternate I to be true. Having learned nothing as to the whole class of X's, we are at liberty to assert also that the A is true. Or, with equal right, we may assert that O, the subcontrary, is true; but, if so, the A, its contradictory, must be false.

The received rules of inference by conversion.

72. By Conversion we gain a consequent, which must be admitted if the antecedent is admitted. When the conversion is thorough, the consequent must also be denied if the antecedent is denied. Thorough conversion is reciprocal. But a defect in the received method of converting A makes it an exception: the denial of A, as antecedent, does not enforce the denial of the proposition usually accepted as its consequent.

The common doctrine of Conversion may be explained as follows:—

Conversion of a proposition is the transposition of its terms. The antecedent is called the Convertend, or Exposita (the proposition set forth to be converted); the consequent is called the Converse (the given proposition converted). The formal rule is this: that no term which was undistributed in the convertend shall be distributed in the converse. The reason is plain. Conversion is an illative or inferential process: it aims, in the narrowest view, at deducing a proposition which must be true if the given proposition is true; and from an assertion of "some" given as true, we cannot deduce an assertion of "all" as true. The received propositional forms, A, E, I, O, being regarded as

the only cognizable forms, the non-distribution of terms in some of these makes it impossible, that each of them shall yield a converse of the same form as the convertend. Accordingly, three methods of conversion are laid down, as applicable severally to the several forms: Simple Conversion; Conversion *Per Accidens*; Conversion by (properly through or after) Contraposition.

(1.) Simple Conversion is a mere transposition of the terms of the convertend, both quantity and quality remaining unchanged. We may thus convert E, which, distributing both terms, yields another E. The given predicate, being distributed, becomes legitimately the subject of a universal: the given subject, being distributed, becomes legitimately the predicate of a negative. Thus, also, we may convert I, which, distributing neither term, yields another I. The predicate, though undistributed, is legitimately usable as the subject of a particular: the subject, though undistributed, is legitimately usable as the predicate of an affirmative. Thus: "The X's are not any Y's," gives, "The Y's are not any X's." "Some X's are some Y's," gives, "Some Y's are some X's."

(2.) Conversion *per accidens* is a transposition of the terms of the convertend, without change of the quality, but with a limitation of the quantity from universal to particular. A is not convertible simply into an A, because its predicate is undistributed. But we may convert it, *per accidens*, into an I: its predicate, though undistributed, may become the subject of a particular. "All X's are some Y's," cannot become "All Y's are X's;" but it does give, "Some Y's are X's." Thus, also, it is said, we may convert E into O. But the process yielding the O is really double: its second step is an inference from subalternant to subalternate. "The X's are not Y's," gives, by simple conversion, "The Y's are not X's;" whence comes, by subalternation, "Some Y's are not X's." For E, indeed, the process is seldom, if ever, put to use.

(3.) Conversion through Contraposition is truly, like the conversion of E into O, a double process. From the convertend there is first inferred an equivalent *contraposita*; and then this *contraposita* is converted. This complexity must be exhibited, if we are to explain rightly the character of the process. Being usually required only for O and A, it is treated in most of the books with exclusive reference to them. But it covers E likewise. (1.) O cannot be converted directly. For its subject, being undistributed, cannot become the predicate of a negative; and the attempt to infer an affirmative with the same terms, would be self-evidently absurd. But, the negative sign of the copula being transferred to the predicate, we have thus inferred, from the O, its *contraposita*, an equipollent I: "Some X's are not Y's," becomes "Some X's—are—(some) Not-Y's." This *contraposita* I is then simply converted into another I: "Some Not-Y's are X's." (2.) A, though convertible directly, *per accidens*, is also convertible through contraposition. We first contrapose, by substituting, for the affirmation of the predicate, the denial of its contradictory, which transforms A into E: "All X's are (some) Y's," gives, "The X's—are not—(any) Not-Y's." The *contraposita* E is then simply converted into E: "The Not-Y's—are not—(any) X's." (3.) E also is evidently so convertible: its *contraposita* is an A, the converse of which, *per accidens*, is an I. But, for E, no use is made of the process. (4.) I is evidently not so convertible: its *contraposita* would be an O; which does not admit direct conversion.¹

¹ The Rules of Conversion, by all its three methods, were symbolized by the schoolmen in two mnemonic lines, in which the vowels of the nominative words designate the forms A, E, I, O.

"Fecit simpliciter convertitur; eva per accid.;
Faxo (or asto) per contra.: sic fit conversio tota."

If, the antecedent being true, the consequent is therefore true, why

Doctrine of inference.

Some logicians, both ancient and modern, have denied, on insufficient grounds, the competency of conversion through contraposition. They hold O to be inconvertible; and, of course, they decline to use the indirect process for A. They thus narrow our power of dealing with the two most difficult of the syllogistic moods.

Systematization of the rules of conversion.

73. The received doctrine, when reduced thoroughly to a system, gives the following results:—

(1.) There are really no more than two methods of conversion: conversion simple, applicable to E and I; conversion *per accidens*, applicable to A. O is not convertible by either method.

(2.) Every proposition admits contraposition; and of every form, except I, the contraposita is convertible. O becomes thus convertible indirectly, but not otherwise: its contraposita, an I, may be converted simply. A and E also are convertible through contraposition: the contraposita of A, being an E, is convertible simply; the contraposita of E, being an A, is convertible *per accidens*.

(3.) Since the converse of E admits a subalternant, E is thus indirectly convertible into O.

(4.) The four received forms of propositions thus admit, either directly or indirectly, the following converses, all of which are currently recognized:—A yields directly I, indirectly E; E yields directly E, indirectly O; I yields directly I; O yields indirectly I. E yields also, indirectly, an I, not currently recognized.

The rule by which these processes are guarded, and the directions given for its use, are traceable upwards, by a very short resolution, to the law of non-contradiction, as brought to bear on predication through common terms. The objects denoted by the subject (of which the quantitative sign is an integral part), and the objects denoted by the predicate (the quantitative sign again considered), are thought as identical when the convertend is affirmative, as non-identical when the convertend is negative. If both convertend and converse affirm when the objects are thought as identical, and deny when the objects are thought as non-identical, each of the terms may be indifferently subject or predicate. The rule, as to distribution of terms, simply prohibits us from interpolating, through either term of the converse, assertion in regard to any objects not named in the convertend.

Supplement to the doctrine of conversion.

74. The strict application of the law of identity shows, at a glance, that the converses of E, I, and O, must be false if the convertends are false. It shows also that, and how, this consequence should, but, on the ordinary interpretation of I, does not, follow as to the converse of A.

Whenever "all" is given in the convertend, we are unquestionably entitled to "all" in the converse. We have a right to infer, in converting A, not I merely, but I². "All X's—are—some Y's," being an affirmation of the identity of subject and predicate, yields, lawfully, "Some Y's—are—all X's." If the A is denied, so must the I² be: if it is denied that "All men—are—(some) liars," it must be denied that "Some liars—are—all men (the only men)." But, I² being unacknowledged in the orthodox scheme, the recognized and only possible converse of A is I: and, manifestly, though it were denied that "All the X's are some Y's," this does not necessitate the denial that "Some Y's are some X's."

Is the received converse of A, then, logically incorrect? Not in the least. The case is only that, read as an I, it

alleges less widely than it might: the fault, like every other¹ in the current systems, lies on the side of safety.

Doctrine of inference.

The truth is, that, in the conversion of A into I, there lies hidden a process of subalternation. The A yields I² as its exhaustive converse, which is true if the convertend be true, but false if the convertend be false. The I, which is usually accepted as the converse of the A, is virtually a subalternant of this full converse: it is true, by the principle of subalternation, if its subalternant is true; but it may, by the same principle, be either true or false if its subalternant be false.¹

The process of conversion has thus been considered from the common position, with the one exception of A. Its laws have been referred to the principle of non-contradiction, as it affects propositions regarded without the analytic dissection of the wholes of the common term. So long as we do not seek to apply the process to any use beyond the determination of the consequent, no deeper analysis is required.

But, when we have to consider the bearing of conversion on the syllogism, it will become imperatively necessary to look at the process from a more commanding station. Its true character, as being a transference of predication from extension to comprehension, or contrariwise, will then come out with irresistible force of evidence.

75. In the preceding treatment of the doctrine of immediate inference, no predicative forms are accepted as data, except the received propositions of inclusion and exclusion, from and to

Inferences from and to propositions of constitution.

¹ This cryptic process may be brought to the surface without I², but still more readily through it.

(1.) Let both A and I be given: "All the X's are some Y's," and "Some X's are some Y's." The I, "Some Y's are some X's," which we are required to accept as the converse of the former, is the full and genuine converse of the latter. Surely it will not be maintained that the subalternant can yield no wider inference than the subalternant. Our process implies our having first inferred an I from A by subalternation, and then simply converted the I. It is thus, in fact, that the conversion of A into I is justified by Boethius. (*Opera*, p. 575.)

(2.) If I² is taken into account, there emerges a relation of the propositions, which is disguised by the imperfection of the quantitative signs, yet is exactly conformable to admitted logical laws. I is virtually a subalternant of I², and is therefore inferrible from it. Given I²: "Some X's—are—all Y's (the only Y's)," we find I: "Some X's (fewer than the first 'some')—are—some Y's." If a part of the X's constitute a whole class Y, then, plainly, a part of that part of the X's must constitute a part of the class Y. When we compare our two propositions, we discover that our indeterminate particularity, though still indeterminate, has shrunk in the higher limit of its dimensions. The "some X's" of our I are only "some of the some X's" of our I². It is true that "Some mortal creatures are all (the only) human beings:" and what follows, on the principle of subalternation, is, that "Some of those some mortal creatures are some human beings."

The question raised by the assumed falsehood of A is here equally easy of decision. There is no inconsistency in our holding I² to be false (as it must be, if the convertend A is so), and in yet finding it impossible to determine whether the subalternant I be false or true. Our denying an assertion, made as to the whole of the first and larger part of our X's, does not give the slightest reason for denying the same assertion as to a part of that part.

In that aspect of the case which was first presented, the conversion of A into I was alleged to imply a subalternation followed by a conversion: in the other aspect, it has been alleged to imply a conversion followed by a subalternation. The two views, though the latter more directly than the other, conduct us to the same result. It is demonstrable, on grounds purely logical, that, when we accept, as a conversion of A, its transformation into an I, the inference covers a part of the subject-class, which, although indeterminate, is yet smaller, possibly or actually, and must necessarily be thought as smaller, than the part as to which the inference might have been drawn. If, therefore, in a process of reasoning, an A is one of our steps, and if, requiring to convert it, we content ourselves with I, we are indeed safe as to the subsequent progress of the argument; but we have narrowed our data in a way which may force a narrowing of our ultimate result.

do geometers prove both a theorem and its converse? Because the proposition which they (and all of us, sometimes, in common speech) call a converse, is not a logical converse. It has not either term the same with either term of the proposition which is nominally its *exposita*.

Doctrine of A, I, E, O. Nor has it been necessary to take account of inference. any other forms, unless in showing that I^2 gives the only full expression for the converse of A.

If the two propositions of constitution, A^2 and I^2 , are combined, first with each other, and afterwards with each of the four received forms, there appear nine pairs of predications, involving a new series of relations. These are singularly barren as grounds of immediate inference. The fact intimates, not only how seldom such assertions can enter into our ordinary trains of thinking; but likewise how little reason there is for hoping, that their incorporation with the received scheme would materially increase the applicabilities of logical science.

One striking point is this. No two of the new pairs of propositions would be formally contradictories: no two are so related, that the one must be true and the other false. We gain only relations corresponding to subalternation and contrariety, with one which resembles subcontrariety.

This supplementary scheme of inference, in short, is philosophically interesting rather than practically useful. The subjoined summary will indicate all the results that can here be dealt with.*

* The details may be gleaned from the table given (with warning that it "may not be quite accurate in details"), by Hamilton, *Discussions*, Appendix, ii., p. 637. In that table, a distinct separation is made, between the relations arising out of the two interpretations of the limitative sign, as "some at least," and "some at most;" both of which Sir W. Hamilton desires to introduce into the science. Neither of the interpretations seems to be excluded by Mr Thomson in his "Tables of Opposition of Judgments." (*Laws of Thought*, ed. 1854, p. 197.) Notice has already been given, that, in the present treatise, the received interpretation, "some at least," is steadily adhered to: if there be any deviation, it is an oversight.

1. The following four pairs of propositions are virtually contraries: A and I^2 , A^2 and E, A^2 and O, I^2 and E. On the assumption, that the "some" is "some at least," both cannot be true, but both may be false. We may infer, therefore, from the truth of either to the falsehood of the other, but not inversely.

2. On the same assumption, these two pairs are virtually subalterns: A^2 is subalternant, I is subalternate; I^2 is subalternant, I is subalternate. If the subalternant is true, the subalternate is true, and may be inferred from it. If "All X's are all Y's," it follows, that "Some X's are some Y's," the quantity of both terms is expressly limited. If, again, "Some X's are all Y's," it follows, that "Some X's are some Y's." The quantity of the predicate is expressly limited, but that of the subject also is limited in reality: the "some X's" which are identical with "some Y's," are not thought as being as extensive with, but as being possibly only a part of, the "some X's" which are identical with "all Y's."

In regard, however, to those six pairs of propositions, the opposite interpretation of the "some" would leave the relations unaffected. As to the other three pairs, the case stands quite otherwise.

3. In either view, I^2 and O approach the relation of subcontraries. (1.) If the "some" is "some at least," the two propositions stand thus:—If I^2 is true, O must be false; admitting I^2 , therefore, we may inferentially deny O. But, if O is true, I^2 may be either true or false. And both may be false. (2.) If the "some" is "some at most," then, since this excludes "all," I^2 being true, O is inferentially true likewise. If it be assumed as true (see Hamilton, p. 636), that "Some dogs (but not all) are all animals that bark," it must follow, as true, that "Some dogs (but not all) are not any animals that bark."

4. The two pairs still to be considered are, A^2 and A, A^2 and I^2 . The relations of both are troublesome. By Mr Thomson these pairs are described as "inconsistent," (that is, as affirmatives standing in the relation of contrariety). In Hamilton's table, the pairs are "inconsistent" on the assumption of "some at most:" on the other assumption, they are not marked at all; but neither is any inference stated as admissible from the one to the other. In other passages, however, Sir W. Hamilton seems to disallow the consistency of A^2 and A, from which doctrine would follow the inconsistency of the other pair.

(1.) If the "some" is "some at most," the pairs stand, plainly, in relations of contrariety; the causes of the inconsistency lying more or less deep according to the quantity of the terms. (2.) If the "some" is "some at least," it is not easy to discover sufficient reasons for refusing to classify the pairs with the other subalterns. Nor, in this view, in the first place, A is only an incomplete or

cautious assertion of A^2 , and may safely be inferred from it: if it is true that "All X's are all Y's," it must be true that "All X's are at least some of the Y's, and perhaps all of them." Or we might take the question thus: If the X's constitute the class Y, every individual X must be identical with some one or other of the Y's. This, perhaps, is the plainer case of the two. If, again, the limitation, which here falls on the predicate, were to be transferred to the subject, the A^2 would yield I^2 . "Some at least, and perhaps all, the X's, are all Y's." But as to this derivative assertion (I^2), even though we should be satisfied that it sustains the formal test, we cannot but see that it serves no use. The limitation of the predicate had given us, in the A, an assertion easily thinkable as contained under the admitted A^2 : but the limitation of the subject is virtually a thinking away of our A^2 , and the substituting, in its place, of a judgment which leaves the A^2 as doubted.

This glance towards the practical side, suggests yet a wider consideration. Using words in their ordinary meanings, no one would dream of inferring, from A^2 , either A or I^2 . But why? Because our spontaneous "some" is always "some at most, some not all." In any use, therefore, which is not guarded by technical rules, the pairs would do duty as contraries.

Still, it must be added (not without reluctance), the more cautious interpretation of the "some" is, in the first place, the only one that can be brought to bear on the received logical system. That system falls to pieces as soon as the other interpretation is let in. Inference, for instance, from subalternant to subalternate, with all its syllogistic applications, requires the former as a foundation. Again, it has not yet been made unquestionable, that the "some not all" is positively required, even for the new system which has been proposed as supplementary to the old. At all events, the dealing with it must be left to those by whom the thorough development of the new system may be undertaken.

CHAPTER III.

CATEGORICAL INFERENCE, MEDIATE OR SYLLOGISTIC.

DIVISION I.—THE FORMAL DOCTRINE OF THE SYLLOGISM.

ARTICLE I.—*The Form of the Syllogism.*

76. A simple Categorical Syllogism has three terms: the Major, the Minor, and the Middle.¹ Each of these occurs twice in the process. The minor and major terms are, respectively, the subject and the predicate of the consequent, and are often spoken of as the Extremes. The middle term is that which appears only in the antecedent. All the three names are significant. The middle term is introduced merely as a standard by which each of the other two may be measured: and, when an affirmative syllogism is reduced to its normal shape, this term is found to stand between the others, including the one, and being included in the other.² In a syllogism so reduced, the minor term is seen to be that term which is included in the middle, the major term to be that which includes it.

The syllogism, when fully set forth, has three propositions. Two of these, which together constitute the antecedent of the inference, are called the Premises: and this name is applicable, not merely because they are made to stand before the consequent when the argument is set down for logical analysis, but also because they are the data and presuppositions of the process. The third proposition is the consequent.

¹ This division of the chapter on the syllogism is designed to be an exposition of the received syllogistic scheme, embracing both the formal principles and all the special rules that have practical uses, and deviating as little as possible from the method followed in the standard books. Archbishop Whately's exposition, here as elsewhere, is admirable; and the details of processes are worked out with great exactness by Huyshe, *Treatise on Logic*, 1842. The doctrine is very instructively summed up from a higher point of view by Solly.

² The name "Argument," used commonly and conveniently to signify the process of inference as a whole, was currently applied by old logicians to the middle term. This meaning of the word has uses dialectical or rhetorical. The discovery of arguments, in proof of proposed conclusions, is resolvable into the discovery of middle terms.

Doctrine of inference.

The premise, whose two terms are the major and the middle, is called the Major Premise: the premise, whose two terms are the minor and the middle, is called the Minor Premise: the one proposition which is the consequent, and whose terms are the minor and the major, is called the Conclusion.¹

The order of the propositions is a matter indifferent to the character of the argument. If we propose the consequent, in the shape of a problem or question, to be solved or answered through the antecedent, the conclusion, when ascertained, may stand first; and the premises will then follow as a reason, introduced by causal particles, as "because." But, in logical treatment of arguments, we assume the premises as given, and place them first; and we add the conclusion, introducing it by illative particles, as "therefore."

The order of the premises, again, has been fixed differently in different logical schools. The real course of the argument is best seen when the minor premise is put before the major. Some points of incidental illustration will, even now, become clearest when this order is adopted: and, in the last stage of our dealing with the categorical syllogism, it will force itself on us continually. But, the purpose, in the meantime, being to lay down and explain the received rules, the other order must be adopted. All those scholastic rules and schemes, which depend on arrangement of the propositions, suppose them to stand in this order: Major Premise; Minor Premise; Conclusion.²

The figure and mood of the syllogism.

77. In the Conclusion, as we have seen, the function of each of the terms is fixed. The minor is the subject, the major the predicate. The fact which fixes it is, the rejection of all propositional forms except A, I, E, and O. If the other possible forms were admitted, the function of the terms in the conclusion would be indifferent.

The function of the terms is not fixed in the Premises. The Middle Term, occurring once in each of these, may have its function varied in any of four several ways; and each of these variations may, in certain circumstances, be adopted without invalidating the argument. Accordingly, there are four admissible variations of the function of the middle term; and these yield the Four Syllogistic Figures. The Figure of a syllogism is its structure with reference to the function of the middle term. Figure, accordingly, is determined exclusively by the premises.

In the First Figure, the middle term is the subject of the major premise, and the predicate of the minor; in the Second Figure, it is the predicate of both premises; in the Third Figure, it is the subject of both premises; in the Fourth Figure, it is the predicate of the major premise, and the subject of the minor.³

¹ Other designative names have been given to the premises severally, but with varieties of application. The major has been called the Proposition, and, by some of the Germans, the Rule (a name bearing on the first figure). The minor has been called the Assumption, a name fitter perhaps for the major. It has more aptly been called the Subsumption (= position of minor under middle); and this name, like so many others of the science, has found its way into the nomenclature of business: the word lingers, though with almost total loss of meaning, in the forms of Scottish law-writs. Hamilton calls the major premise the Sumption, the minor the Subsumption.

² Hamilton has summed up much information as to the order in which the premises have been arranged at different periods in the history of the science. (*Discussions*, p. 645; and note in Thomson's *Laws of Thought*, 1854; p. 224.)

³ The fourth figure emerges, necessarily, when we look at the syllogism in this unanalytic way, asking only whether the middle term is subject or predicate. But the figure falls away, as being a variation of the first, if, dissecting the premises, we inquire which term is contained in which. So examined, the syllogism gives three figures only: the first (covering the fourth), in which the middle term is between the extremes; the second, in which it stands above both; the third, in which it stands under both. Aristotle, adopting this deeper analysis, and fixing no order of premises, recognised

The subject being always understood to stand before the predicate, the following table exhibits the position of the terms in each of the four figures. Here, and afterwards, M denotes the middle term, S the minor, P the major.

	Figure I.	Figure II.	Figure III.	Figure IV.
Major Premise.....	M P	P M	M P	P M
Minor Premise.....	S M	S M	M S	M S
Conclusion.....	S P	S P	S P	S P

The structure of a syllogism, in reference to the quantity and quality of its propositions, is called its *Mood*. Those forms of predication only being taken into account which are denoted by A, E, I, and O, the moods arithmetically possible are sixty-four. For any one of the four forms might supposably be either major premise, minor premise, or conclusion; and each, appearing in any one proposition, might be accompanied in each of the other two propositions by any form of the four. But, as we shall immediately learn, a very large majority of the sixty-four moods would produce arguments totally invalid.

ARTICLE II.—The Principle of the First Syllogistic Figure.

78. By a large majority of logicians, the First Figure has been recognized as the normal form of the syllogism. In support of this opinion there is alleged the fact, that in this figure, and in it only, the middle term, the sign of the syllogistic thought through which the other two terms are united in one judgment in the conclusion, occupies its just place in relation to the other two: it includes the minor term, and is itself included either in the major term or in its contradictory. The character of the first syllogistic figure.

The terms are so related in the following syllogism of the first figure, in which, to exhibit the relation more clearly, the minor premise is placed before the major:—"All the S's are M's; all the M's are P's: therefore, all the S's are P's." "The minor is included in the middle; the middle is included in the major: therefore, the minor is included in the major."

So is it, too, though the syllogism have a negative conclusion; as thus: "All the S's are M's; the M's are not P's: therefore, the S's are not P's." For the argument may be analysed in this way:—"The minor is included in the middle; the middle is included in the contradictory of the major: therefore, the minor is included in the contradictory of the major."

Let us examine, generally, the character of an argument thus framed. In the first place, it bears on the face of it a reference, more direct than that made by any other form, to the principle of non-contradiction. It is an unmistakable passage from one identity or non-identity to another. It is a formula exemplifying a law: "things which are identical with the same thing are identical with each other." In our affirmative example, it was asserted that S is identical with a part of M, and the whole of M (including, of course, that part) with a part of P. Hence it was inferred, that S is identical with a part of P, or that the things called S are the same things which, with other things, are called P. To the negative example the same reasoning is applicable, with the substitution of Not-P for P.

In the next place, such an argument exhibits, in their natural order of sequence, the steps of a process of deduction. It is asserted that a given case is included in a class of cases, which are known to be governed by a law or principle assumed as already established. It is inferred that the given case is governed by that law or principle. "The

three figures only; and on this view we must in the end fall back. The source whence the schoolmen borrowed the fourth figure is doubtful. This figure has, by long tradition, been ascribed to Galen; but, after careful inspection of the fragmentary logical notices scattered through his medical writings, both Hamilton and Trendelenburg have failed to discover it.

Doctrine of given case S is included in the class of cases M; the whole inference. class of cases M is governed by the law P (or No P): therefore, the case S is governed by the law P (or Not-P)."

The dictum in its reference to the whole of extension.

79. Accordingly, there has been assigned, as the supreme and only original Law of the Syllogism, the maxim which, from one of its expressions, is called the *Dictum* (or *dicta*) *de omni et de nullo*. In all its shapes, it considers two of the terms as constituting an ordained series. But it is usually framed so as to interpret the ordination from the side of extension; seldomer so as to interpret it from the side of comprehension. It must be examined in both aspects.

(1.) The *dictum*, as it appears when the terms are read in extension, is most frequently enounced in such a shape as this: "Whatever is predicated (affirmatively or negatively) of a class, may be predicated in like manner (that is, affirmatively or negatively) of everything included in the class." A closer approximation to the scheme of the predicables is gained by this expression: "Whatever is predicated of a genus, is predicable also of a species included in the genus."¹

In the major premise: Of a class or genus M—there is affirmed or denied—some thing denoted by P.

In the minor premise: The species S—is affirmed to be —included in the genus M.

∴ In the conclusion: Of the species S—there is affirmed or denied—that which is denoted by P.

The terms directly ordained are the middle and the minor; the former is the genus, the latter an included species. The major term denotes an attribute, which is asserted to be possessed or not possessed by the genus, and which, therefore, through a double subalternation, is inferred to be possessed or not possessed by the species. "All the M's have the attribute P (and, consequently, some M's have it); but the S's are some M's: therefore the S's have the attribute P."

Again, in the dictum, as thus read, the major term is not expressly embraced in the ordination. It does not directly require to be so. In both of its appearances it is a predicate, interpretable as the name of an attribute; and therefore it does not necessarily receive a place in a series constituted by terms which are regarded as the names of classes, containing objects or substances. But its place, as the most extensive term in the ordination, is unavoidably implied: it is impossible to read, analytically, any syllogism exemplifying the dictum, without bringing this relation to light. The three propositions of a syllogism purely affirmative, are assertions of three successive and widening steps of inclusion: the propositions of a syllogism which introduces negatives are readily and correctly interpretable in the same way, if only we substitute for the major term its contradictory.

The completed ordination of the terms in extension, from narrowest to widest, is this: "S, M, P (or Not-P)." This gradation is explicated, step by step, when the syllogistic propositions are arranged thus: minor premise, major premise, conclusion. "All (or some) S's are in M; all M's are in P (or in Not-P): therefore all (or some) S's are in P (or in Not-P)."²

¹ Quidquid de omni valet, valet etiam de quibusdam et singulis (the "dictum de omni"); quidquid de nullo valet, valet nec de quibusdam nec de singulis (the "dictum de nullo").—Quidquid valet de genere, valet etiam de specie: quidquid repugnat generi, repugnat etiam speciei.

² This resolution of negative syllogisms into affirmatives is, evidently, through contraposition of the major premise and the conclusion. It is possible in the first figure, because in it the major term is always a predicate. Since, therefore, it is always competent thus to substitute, for a proposition of exclusion, its equipollent proposition of inclusion, the *dictum de nullo* might be dispensed with. But, though the contraposition is often convenient, and though, especially, it gives the clearest view over the ordination of the terms; yet it is not a safe operation where the validity of a chain of syllogisms is under scrutiny. If we were to contrapose a

Otherwise, indeed, syllogisms in which negatives are introduced might, easily, be traced back to a pre-ordination without displacement of the negations. The middle term and the major would, in this view, be taken as co-ordinates, which, by the law of the concept, must be denied of each other. The minor would then denote a species: the middle and major would denote two genera proximate to it, and mutually co-ordinate and exclusive. The ascending ordination would be: "S, M + P."¹

80. (2.) When the terms are read in comprehension, the dictum takes several forms, of which this is the most common: "The mark of a mark is a mark of a thing."² That is, an attribute of a second attribute is an attribute of any object or substance possessing the second attribute. The first attribute is the major term; the second attribute is the middle term; that which is regarded as a substance is the minor term. The negative expression of the maxim is needless, and tends to perplex: it is sufficient, as before, to substitute, when negation is introduced, the contradictory of the major term for that term itself. "If P (or Not-P) is a mark or attribute of M, and if M is a mark or attribute of the object or objects S, then P (or Not-P) is a mark or attribute of S."

The meaning of the rule in this shape is plain; and its truth, as a simple application of the law of identity, is self-evident. The use of it in testing syllogistic examples is troublesome; because it throws us on those abstract phrases, which, though distinctively-significative of the relation of comprehension, are unusual and unmanageable.

We are guided towards concrete phrases, by an expression of the dictum supplied to the schoolmen by Aristotle himself,—an expression which, while it is more readily applicable to comprehension than to extension, does not expressly allege either. It is the widest, and perhaps the most apt, of all the shapes in which the dictum can be couched. "That which is predicated of the predicate, may be predicated of the subject." That which (in the major premise) is predicated of the predicate (of the minor premise), may (in the conclusion) be predicated of the subject (of the minor premise).³

In the major premise: Of M—there is affirmed—the mark or attribute P (or Not-P).

In the minor premise: Of S—there is affirmed—the mark or attribute M.

∴ In the conclusion: Of S—there is affirmed—the mark or attribute P (or Not-P).

In the comprehensive form of the dictum, the terms directly ordained are the middle and the major. The major is in the comprehension of the middle, being a mark of it: the major is the less comprehensive, the middle the more comprehensive, of the two. The minor term denotes a substance or substances, an object or group of objects, which is asserted to possess the attribute denoted by the middle;

negative conclusion, we might, when it next emerges as a premise, require to re-contrapose.

¹ For a characteristically acute statement of difficulties, which the last two or three paragraphs, as well as similar resolutions elsewhere, are designed to meet, see Trendelenburg, *Logische Untersuchungen*, ii., 238, &c. His objections are two: first, that when the dictum is considered in extension, the major term falls out of the scale of subordination; secondly, that when one of the premises is negative, the subordination breaks down altogether.

² Nota notæ est etiam nota rei: (repugnans notæ repugnat rei).

³ Prædicatum prædicati est etiam prædicatum subjecti. "Ὅσα κατὰ τοῦ κατηγορουμένου λέγεται, πάντα καὶ κατὰ τοῦ ὑποκειμένου ῥηθήσονται. (Categ., cap. 5). In toto esse vel de omni prædicari dicitur, quoties non potest inveniri aliquid subjecti, ad quod illud quod prædicatur dici non possit. In toto vero non esse vel de nullo prædicari dicitur, quoties nihil subjecti poterit inveniri, ad quod illud quod prædicatur dici possit." (Boethius, *De Syllogismo Categorico*, Opera, p. 691).

Doctrine of inference.

and it is therefore inferred to possess the attribute denoted by the major, which is a part of the attribute denoted by the middle. "The attribute M comprehends the attribute P (or Not-P); the S's (all or some) possess the comprehending attribute M: therefore the S's (all or some) possess the comprehended attribute P (or Not-P)."

When the dictum was analysed extensively, the major term, being used only as an attributive name, did not require to be expressly referred to an ordination constituted by terms which were considered as names of substances. Now, when the dictum is analysed comprehensively, the minor term, which in both of its appearances is only a name denoting substance, does not require to be expressly referred to an ordination containing terms which are considered as names of attributes. But it may be so referred: and the presupposed series is not complete until the minor term is placed as one extreme of it.¹ The minor term, which was found to be the least extensive of the series, is necessarily the most comprehensive. The completed ordination of the terms in comprehension, from narrowest to widest, is this: "P (or Not-P), M, S." This gradation is, of course, explicated, when the propositions are arranged in the order opposite to that which exhibited the widening scale of extension: conclusion, major premise, minor premise. The retention of the negative predications might here, as in the other view, be justified through the assumption of co-ordination, and consequent exclusion, between the middle term and the major.

The special laws of the first figure inferred from the dictum.

81. The *dictum de omni et nullo*, in all its forms, is plainly nothing more than a corollary, or pair of corollaries, from the principle of predication through common terms. It is required only to accept two, at most, of the special laws deduced from that principle; and to explain their applicability to cases in which the antecedent is not one proposition but two. *The Law of Affirmation through Subalternation*, expressed so as to cover more degrees than two, guides us through all syllogisms purely affirmative: while, as it has been shown, the negations of a syllogism may be displaced, and this one law be applied to all. If given negations are retained, we have only to accept, along with the law of affirmation through subalternation, *the Law of Negation through Co-ordination*.

The first figure is subject to three Special Laws. These, though they are proveable, and will be proved, otherwise, are deducible, readily and instructively, from the dictum. The extensive form of the dictum is most conveniently available for the purpose.

(1.) The Minor premise must be Affirmative. In that premise, the minor term is subject, the middle is predicate. The rule therefore says, simply, that the minor term must be included in the middle, not excluded from it; that it must be describable (if it be a common term), as one of those species which the middle term, a genus, is supposed to contain. If it were not so included, so describable, nothing would be asserted to be "contained in the class," no species to be contained in the genus. Whether the major term were affirmable or deniable of the middle, there would be no data for determining whether it were affirmable or deniable of the minor. In a word, there would be wanting the lowest step of the ordination in extension, the step out of which all the others come.

The middle term signifies a class; the major signifies an attribute belonging to the class, or wanting in it. The minor signifies something which is placed in that class; and, being so placed, it must possess the class-attribute, or want an attribute not found in the class. The middle term is in-

roduced to be a link in thought between the minor and the major: it is clasped to both. But, if the minor is not in the middle, the hold on that side has snapped.

Doctrine of inference.

(2.) The Major premise must be Universal. In that premise, the middle term is subject, the major is predicate. Consequently, the rule alleges, that the whole class designated by the middle term must possess the attribute denoted by the major; or, in other words, that in this premise the middle term must be distributed. The reason stares us in the face. For the minor premise asserts, not that the minor term constitutes a class M, but only that it is in that class, or makes some part or other of it. If, then, it were only alleged, in the major premise, that some part or other of the class M possesses the attribute P (or Not-P), this might or might not be the same part which has been affirmed of S. The identity of S with a part of M possessing P, or its contradictory, cannot be made peremptory at any cheaper rate, than the assertion that the whole of M possesses P, or its contradictory.

But, it is to be observed, this necessity, for distribution of the middle term in the major premise, arises out of two features in the minor premise. *First*, That premise has an undistributed predicate (M): it affirms only that S is some part of the class M. *Secondly*, It affirms only that S is some undetermined part of M. Suppose that the part of M were there definitely identified; and that a part of M similarly identified were to become subject of the major premise. It might then be determinable, and signifiable through the form of expression, whether the part first named and that named second were one and the same, or two several parts. In the former case, the chain of identity would be unbroken: in the latter, it would be broken, and further progress from contained term to term containing would be impossible.

(3.) The Quality of the major premise determines the quality of the conclusion; the Quantity of the minor premise limits the quantity of the conclusion. This law, in both of its parts, is almost self-evident to every one who understands the character of the syllogism.

In the major premise it is asserted, either that the middle term has, or that it has not, the attribute denoted by the major term. If it has the attribute, the minor term also must have it, being a part of the middle: if the middle wants it, so must the minor. The minor premise, again, affirms, that either the whole class denotable by the minor term, or a part only of that class, is in the middle. If it has affirmed of the whole class, the predication in the conclusion may be made of the whole class (though, of course, we might hence subalternate to a part): if it has affirmed of a part only, it is of a part only that we can predicate in the conclusion.

ARTICLE III.—*Laws, Universal and Special, of the Syllogistic Figures.*

82. The *dictum* may be brought to bear on any syllogism whatever. For every syllogism of the second, third, or fourth figure, admits of being transformed into a syllogism of the first. But it is desired by those who hold the pre-eminence of the first figure, and insisted on by some of those who deny it, that we be enabled to test every syllogism as given, without questioning as to its figure, or making any change on its structure.

Such a test is supplied by two rules, the first justifying conclusions which are affirmative, the second those that are negative. They have been called the *Canons of the Syllogism*.

They are these: "Two terms which agree with the same third term, agree with each other. Two terms, whereof the one agrees and the other disagrees with the same third term, disagree with each other."

¹ Consult, again, for the questions raised here and in the last section, Trendelenburg, ii., 239. He there animadverts on the "*Nota nota*," (the form of the dictum adopted by Kant), which he rightly recognises as a reading of the dictum in comprehension.

¹ These expressions of the canons are, in substance, Aldrich's and

Doctrine of inference. Two terms are said by many logicians to "agree," or to be "congruent" or "consistent," when they may be the terms of an affirmative proposition. Two terms are said to "disagree," or to be "incongruous" or "inconsistent," when they can only be the terms of a negative proposition. This phraseology being adopted in the canons, agreement of terms in a given proposition is affirmation, disagreement is negation. The two terms first mentioned are the Minor and Major, the third term is the Middle.

The canons, accordingly, are interpretable by direct reference to the character of the copula in each of the three propositions of the syllogism. They might thus take the following shapes:—

First, "If there are given, as premises, two propositions, in which there is asserted, between M as one term, and S and P successively as the other term, a relation expressed by affirmation, there is implied, between S and P, a relation which must be expressed by affirmation in the conclusion."

Secondly, "If there are given, as premises, two propositions, in which, between M as one term, and S and P successively as the other term, there are asserted relations, which are expressed in either of the premises by affirmation and in the other by negation, there is implied, between S and P, a relation which must be expressed by negation in the conclusion."

So interpreted, the canons are evidently direct applications of the laws of identity and difference; for affirmation is the expression of identity, negation of difference.

The identities and differences are explicable in this way. 1. Two things, or groups of things, which are identical with a third thing, or group of things, must be identical with each other. If it be assumed that both S and P are identical with M, S and P must be identical with each other; or the names S and P are but two names for the same thing, or group of things. 2. If, of two things, or groups of things, the one is identical, the other non-identical, with a third thing, or group of things, the two must be non-identical with each other. If it be assumed either that S is identical, and P non-identical, with M; or that S is non-identical, and P identical, with M: S and P must be non-identical with each other; or the names S and P are names for two different things, or groups of things.

If we accept, and steadily keep hold of, the quantitative signs, "all, any, some," as integral parts of the terms, the applicability of the canons, as expressions of the two primary laws of predication, is thorough-going. It is plain, too, that the canons, in all their expressions, leave the function of each of the terms, as subject or predicate, completely open for all the three propositions. The only limitation is, the prohibition of all forms except A, E, I, and O.

The weakness of the canons lies, first, and positively, in their leaving the quantitative signs unaccounted for. The reasons which make these possible and necessary, do not emerge till we fall back on the dictum, and on those laws

Whately's. They are thus given by Burgersdyk, as bearing on syllogisms having a singular as middle term,—the "expository syllogisms" of the schools: "*Quæcunque uni tertio singulari conveniunt, ea quoque inter se conveniunt. Quorum unum alicui tertio singulari convenit, alterum non convenit, ea quoque inter se non conveniunt.*" Smiglecius carries them up directly to Identity and Difference: "*Quæ sunt eadem uni tertio, sunt eadem inter se. Quando est idem alicui, cui aliud non est idem, ipsa quoque non erunt idem inter se.*" (*Disputatio xiii., Quæstio 14.*) Keckermann unites the two, calling the complex law "The Principle of Proportion," that is, the principle in virtue of which the middle term becomes a measure of the other two: "*Quæcunque in uni tertio conveniunt, inter se conveniunt: quæ vero in uni tertio dissentiunt, inter se dissentiunt.*" (*Systematis Logici*, lib. iii., cap. 5.) This form requires a gloss: the agreement or difference "in" the middle term, is agreement or difference in the quality of the premises;—the reference of the syllogism to the canons, as universally superseding the dictum, was a step not taken till the latest times of scholasticism; and it has very frequently been protested against.

of common terms out of which it has grown. But it may even be questioned, whether the canons do not necessarily, —whenever the use of them requires interpretation of the quantitative signs,—presuppose the dictum, or the law of logical totality, from which the dictum itself springs.¹

83. The canons, then, enable us to consider every syllogism, whatever be its figure, as constituted by three assertions of identity or difference between the three terms, taken two and two. But, in order to determine positively what the objects are, which are asserted to be identical or different, we have to hold the quantitative sign of each term as being a part of it; and, in order to test decisively the question of identity or difference, we have to assume that "all" includes "some," or that a whole includes its part.

On this footing there are deducible from the canons six maxims, which are describable as Universal Rules of the Syllogism. Violations of these are, for mediate inference, the only Fallacies, or faults making an argument inconclusive, which logic can detect without extraneous aid.

(1.) A Syllogism has Three Terms. It is invalid if it has either fewer or more. A proof of this rule would be merely a repeated description of the nature of the syllogism; and, if the rule is accepted with presupposition of its reasons, the rules of quantity may be regarded as corollaries from it. The violation of any of them is resolvable into the introduction of a fourth term.

Fewer terms than three no syllogism is in any danger of having. But, seeming to have three only, it may really have more than three, through the ambiguity of words. This rule, indeed, is designed chiefly as a preliminary caution, against the fallacies which may insinuate themselves into reasoning by means of the fact, that there is no term, how-

¹ These two paragraphs may call for some illustration.

(1.) Given this syllogism in AII: "All M's are P's; some S's are M's: therefore some S's are P's." The data here are not the classes S, M, and P: the identity or non-identity of these classes as wholes is not put in question. The quantity of predicates being brought out, it appears that our terms are these: "some S's;" "all M's," ("some M's," however, being implied, and requiring to be explicated); "some P's." The assertions of identity are these: (1.) The objects called "all M's," are the same objects which are also called "some P's;" (2.) The objects called "some S's," are the same objects which are also called "some M's:" therefore (3.), the objects called "some S's," are the same objects which are also called "some P's."

(2.) Even when the quantitative signs are thus incorporated, there is still required, as the example shows, one interpretation of them. We cannot gain our inference, without assuming that "all" implies "some." If this assumption is refused us, we cannot show that the premises assert the identity of S and P with the same third term. But how do we come by the assumption? Can we do so without the idea of classification? Or can classification supply it, unless through the dictum or its principle?

If this doubt is well-founded, the canons are even weaker than the text has positively alleged them to be. They are sufficient, without the dictum, to justify syllogisms having a singular middle term. They cannot justify syllogisms whose middle is a common term, unless through a presupposition, of which the dictum, or the higher law of conceptive totality, is an element.

However, the assertion may be held to rest on the still wider truth, that a whole contains its part.

(3.) In spite of theoretical difficulties, the convenience of the canons is great. And, if the quantitative signs are taken as integral parts of the terms, and if, also, interpretation of these is admitted to the extent of the implication of "some" in "all," they do, as alleged in the text, carry us through syllogisms of any form. When, again, the conclusion is an E or an I, it is a matter of indifference to the application of the canons, which of the terms S and P is subject of the conclusion, and which predicate: the terms of E and I are reciprocal; and simple conversion yields a new E or I. But conclusions in A and O tie us down to S as subject, and P as predicate. A is convertible only into I², a form not received: O is not directly convertible at all. The fact that conversion would change the character of the predication in reference to the wholes of the concept, is not forced on our consideration when we test a syllogism by the canons.

Doctrine of inference. be capable of bearing more than one signification. If any name furnishes a term susceptible of two meanings, and if it bears one of these on its first appearance in a syllogism, and the other in its second, it has really furnished not one term, but two; a term denoting one set of objects, another term denoting a different set. The syllogism, therefore, has four terms, not three; and, at some point or other, the chain of comparison is broken. The middle term is, unquestionably, in greater danger of having two meanings, than either of the other terms is: and the intrusion of a fourth term in disguise is often described as the Fallacy of Ambiguous Middle. But the other terms likewise require to be watched.

(2.) The Middle term must be Distributed in one of the premises. The violation of this rule is the Fallacy of Undistributed Middle.

The rule is a consequence, following from the indefinite character of the part signified by the logical "some." M is introduced into the premises, in order that S and P may severally be compared with it. If it is twice undistributed, it may, for all we know, be double; and, if it is double, the syllogism has four terms. If S were compared with "some part or other" of M, and, again, P with "some part or other" of M, it would be left absolutely uncertain whether they have been compared with the same part, or with two parts that are different. No ground would have been laid down for determining their mutual difference or identity. But, if one of them is compared with the whole of M, and pronounced to be either the same or not the same with that whole, it is enough that the other should be compared with a part of the whole of M: since the first term, having been compared with the whole, must have been compared with this part. Accordingly, one distribution of the middle term is sufficient.¹

(3.) Neither the Minor term nor the Major must be Distributed in the Conclusion, if it was Undistributed in its Premise. Violation of this rule is an Illicit Process, and is, therefore, of two kinds: Illicit Process of the Minor, Illicit Process of the Major.

When we remember that the quantitative sign is a part of every term given in the process, we shall perceive at once that a breach of the rule would amount to the introduction of a fourth term. There is given in the premise a relation between M and "some S's" or "some P's." This gives us no right to infer, in the conclusion, anything in regard to "all S's," or "all P's."²

(4.) If both Premises are Affirmative, the Conclusion must be Affirmative.

This is evident, both from the words of the canons, and from their principle. The case is that which the first canon covers. Assertion of the identity of M both with S and with P, cannot, without self-contradiction, yield assertion of the non-identity of S and P with each other.

¹ In the first and second figures, the middle never is twice distributed. When it is so in other figures, the conclusion obtainable is exactly the same as it would have been if the middle had been distributed only once. The moods, in which the double distribution occurs, have premises needlessly wide for the conclusions.

² The two kinds of Illicit Process are not fallacies lying equally deep. In committing an illicit process of the minor, we have only inferred a universal, A or E, in a case where, if there be no other fallacy, we might have inferred a particular, I or O. The error is easily corrigible. But an illicit process of the major is, when it is the one fault, a fault that is incurable. It is forced on us by our having premises from which no inference at all could be drawn. It is possible only when the conclusion is negative, E or O; these conclusions only having a distributed major. In the premise, then, the major term, being by hypothesis undistributed, must have been either the subject of a particular, I or O, or the predicate of an affirmative, A or I. It will immediately appear, from the special rules of the figures, that, in such circumstances, inference is always impossible.

(5.) If either of the Premises is Negative, the Conclusion must be Negative. Doctrine of inference.

The case is covered by the second canon. If S (or P) is M, and if P (or S) is not M, S and P must be, not one thing, but two different things.

(6.) From Premises, both of which are Negative, no Conclusion can be inferred.

The case, not being covered by either of the canons, is thus virtually excluded; and it is self-evident that the exclusion is right. The assertion that both S and P are non-identical with M, leaves it utterly undetermined whether they are or are not identical with each other.

A violation of the first rule is a fallacy which throws the reasoning out of the very form of a syllogism. Violations of the second and third rules are fallacies of Quantity. Violations of the fourth, fifth, and sixth rules are fallacies of Quality. When the error does not flow from the most abundant of all sources, the ambiguity of terms, the fallacies most likely to occur are those of quantity; namely, undistributed middle and illicit process.¹

There are annexed a few examples, in which the Six Rules are palpably violated.²

¹ There have been laid down several other rules, all of which are truly derivative, either from the six above given, or from other obvious laws.

For example: When a universal Conclusion may be inferred there may be inferred also a Particular. This is nothing more than an assertion of the possibility of immediate inference, from the truth of the subalternant to the truth of the subalternate. But the point is worth observing; since it has a bearing on the scheme of the syllogistic moods.

Two of the scholastic rules deserve the subordinate place assigned to them by Whately. The violation of either of them warns us, that there must have been committed one or another of the fallacies of quantity. They may be numbered as supplementary to the six of the text.

(7.) When one of the premises is Particular, the conclusion must be Particular. The transgression of this rule is a symptom of illicit process of the minor.

This, and the fifth rule of the text, are combined by many of the old logicians into the one rule: That the conclusion, both in quality and in quantity, follows the Worse, or weaker, premise; "Conclusio sequitur partem deteriore." Negation is "worse" than affirmation, particularity than universality.

(8.) From premises, both of which are Particular, no Conclusion follows. The transgression of this rule is a symptom, either of undistributed middle, or of illicit process of the major, the two fallacies which arise out of bad premises.

Premises in OO, as being both negative, are condemned otherwise. Premises in II plainly give undistributed middle. Premises in IO (the major premise first), require O in the conclusion, and give illicit process of the major; while in Figure III. there will also be undistributed middle. Premises in OI give undistributed middle, when that term is subject of the major premise (that is, in Figures I. and III.): they give illicit process of the major, when that term is subject of the major premise (that is, in Figures II. and IV.).

* Breaches of the Six Syllogistic Rules.

Rule 1. Nettles are stinging plants; and fig-trees are nettles: therefore it must be true that fig-trees sting. "All M's—are—some P's; all S's—are—some M's: ∴ all S's—are—some P's" (Ambiguous middle, making four terms).—The fig belongs to a tribe of plants, the typical name of which (Lindley's "Urticales") is taken from the common nettle.

Rule 2. Since many plants are beautiful, and many plants are rare; may we not infer, that among the things that are rare, there are some that are beautiful? "Some M's—are—some P's; some M's—are—some S's: ∴ some S's—are—some P's" (Undistributed middle).

Rule 3. (1.) Interest attaches to all plants, and rarity may be asserted of many plants; is it therefore true that every thing rare is also interesting? "All M's—are—some P's; some M's—are—some S's: ∴ all S's—are—some P's." (Illicit process of minor).

(2.) We infer that there is no beauty in flower-beds; because grassy surfaces are beautiful, and flower-beds are not grassy surfaces. "All M's—are—some P's; any S's—are not—any M's: ∴ any S's—are not—any P's." (Illicit process of major).

Rule 4. Assuming that every exotic plant is interesting, but that not a few such plants are useless; should we be in any danger of

Doctrine of inference. Determination of the eleven valid moods.

84. When the sixty-four possible Moods of the syllogism are tested by the six rules, it is discovered that fifty-three of them do necessarily, whatever the figure may be, yield bad conclusions. None of them can violate the first rule: but all of them violate either rules of quality, or rules of quantity, or rules of both kinds. Accordingly, no more than *eleven* of the sixty-four can ever be valid.¹

First, There are thirty-two moods which appear, on the face of them, to involve fallacies of quality. Our fourth rule is transgressed by AAE, AAO, AIO, IAO; our fifth by AEA, AEI, AOA, AOI, EAA, EAI, EIA, EII, IEA, IEL, OAA, OAI; our sixth by EEA, EEE, EEI, EEO, EOA, EOE, EOI, EOO, OEA, OEE, OEI, OEO, OOA, OOE, OOI, OOO.

Secondly, There are twenty-one moods which, when the distribution of the terms is examined, are found to involve fallacies of quantity.

inferring that few things which are useless are also interesting? "All M's—are—some P's; sothe M's—are—some S's: ∴ some S's—are not—any P's." (Both premises affirmative; conclusion negative).

Rule 5. If all imperfect plants want true flowers, and if true flowers grow on all trees; we are surely not tempted to infer that trees are imperfect plants. "Any P's—are not—any M's; all S's—are—some M's: ∴ all S's—are—Some P's." (One premise negative; conclusion affirmative).

Rule 6. If we wish to determine whether the potatoe-plant is or is not a nightshade (*Solanum*), we shall hardly suppose ourselves to have sufficient data, though we know that neither any potato, nor any nightshade, produces fruit which can safely be eaten. "Any P's—are not—any M's; any S's—are not—any M's." (Both premises negative; no conclusion possible).

In a preceding article of the Encyclopædia [FALLACY], the principal sources of inconclusiveness in argumentation were described in outline. The topic is hardly anywhere treated so thoroughly, and nowhere so practically, as in Whately's dissertation, "Of Fallacies."

Fallacy may have place, either in the *form* of an argument, or in its *matter*. If it is formal, the conclusion does not follow from the premises; and the logical rules expose the flaw. If it is material, the conclusion does follow from the premises; and logical rules have no bearing; but, here, the fault may be, either in the premises, or in the conclusion. Accordingly, all the kinds of fallacy may be distributed in the following way. Either they are *Fallacies of Inference*, which are formal, but may be either *patent* or *latent*; or they are *Fallacies of Assumption* or of *Exposition*, both of which are material. Not infrequently, an argument combines fallacies of more kinds than one.

(1.) A fallacy of inference is patent, when the logical rules detect it without interpretation of terms. It is latent, when interpretation of terms must precede logical analysis. The latency of formal fallacies arises always from the *ambiguity of words*; and the treatises on fallacies, which are so full in many logical works, are chiefly occupied in explaining the causes and kinds of ambiguity. (2.) A fallacy of assumption consists in arguing from one or more premises which are not true or not admitted. It is most frequently latent; the faulty premise being virtually, but not obviously, either identical with the conclusion or dependent on it. This latency is the case of "petitio principii" or "quæsti," the begging of the question; and the name "arguing in a circle" should mean a repetition of this error, by inferring back to something which was really a preceding premise. (3.) A fallacy of exposition is a mis-statement of the question which is at issue. Its scholastic name is "ignoratio elenchi," the ignoring or shunning of the conclusion which would contradict the position of the adversary: the argument has as its result an "irrelevant conclusion," a conclusion different from that which ought to have been proved. This fallacy is signified by the common expression of "shifting the ground." A union of it with ambiguity of terms is perhaps the most frequent of all flaws in reasoning. To it are referable instances in which any principle, rightly pleasurable in some cases, is applied to a case which it does not cover. This is exemplified by the "argumentum ad verecundiam," the appeal to authority; and by the "argumentum ad hominem," the attempt to show that an opponent's position is taxable with inconsistency: and in a similar predicament are illegitimate endeavours to influence judgment through emotion.

¹ Henceforth, in this division, the common order of the premises, as being that which is taken for granted in the received doctrine of mood and figure, must be steadily adhered to. The major premise precedes the minor.

(1.) The supplementary rule, numbered as our seventh, Doctrine of inference. gives notice that the third rule is violated by AIA, AIE, AOE, EIE, IAA, IAE, IEE, OAE.

(2.) The supplementary rule, numbered as our eighth, gives notice that either the second rule or the third must be violated by IIA, IIE, III, IIO, IOA, IOE, IOI, IOO, OIA, OIE, OII, OIO.

(3.) The mood IEO necessarily violates the third rule through illicit process of the major. The major term is distributed in the conclusion; while it cannot, whether as subject or as predicate, have been distributed in its premise.

Not a few of the moods thus excluded, violate evidently more rules than one.

The other moods, which only can ever yield a valid inference, are these eleven: four moods having affirmative conclusions, AAA, AAI, AII, IAI; seven moods having negative conclusions, AEE, AEO, AOO, EAE, EAO, EIO, OAO.¹

85. It must now be considered how the relation of Mood Determination is affected by the relation of Figure.

We see that there are no more than eleven combinations of propositions, which can, in any figure, stand the test of the syllogistic rules. Further, the functions imposed on the terms, as subject or predicate, in the premises of the Four Figures, vary far enough to make us expect, before minute inspection, that a mood may be valid in one figure yet invalid in others. And the fact is so.

The moods are not applicable to use, unless through the adoption of one or another of those modes of constructing premises which constitute the figures. Accordingly, we may henceforth understand, by a mood, a Mood in a given Figure. Of the eleven valid moods, each of the figures admits six: whence, of Moods in Figure, there are in all Twenty-Four. Five of these, however, noted in the following list by italic letters, are unused, as giving particular conclusions where the premises allow the conclusions to be universal. These particular conclusions, indeed, may always be held to have been reached through subaltern inference from the universals.

Figure I. has these moods; AAA, *AAI*, EAE, *EAO*, AII, EIO.
Figure II. EAE, *EAO*, AEE, *AEO*, EIO, AOO.
Figure III. AAI, IAI, AII, EAO, EIO, OAO.
Figure IV. AAI, AEE, *AEO*, IAI, EAO, EIO.*

¹ The moods might be scrutinized, also, in another and quicker way. The exclusion of the bad moods is gained, by far most readily, through this question: How many pairs of premises are there, which, as being neither both negative nor both particular, may yield some conclusion or other? There are nine such pairs; but one of them, IE, breaks down when closely handled. Therefore the valid pairs of premises are only eight: AA, AE, and EA, both universals; AI, IA, AO, EI, OA, of which the one is universal, the other particular. Each of the three pairs of universals admits two conclusions, a universal and a particular: each of the others is tied down to one particular conclusion. The conclusions being supplied, we have the same eleven moods which had been discovered through the more cumbrous process.

* This table allows a comparison of the figures, in reference both to the structure of their syllogisms, and to the forms of propositions which are attainable as conclusions through them. Of many considerations which suggest themselves, the following are the most important:—

I. Of the eleven moods, there are only two which distribute their terms widely enough to sustain, without lapsing into fallacies of quantity, all the changes of structure which the variation of figure causes in premises. These, as we should expect, are negative moods; they are EAO and EIO. But, though these moods are good in all the four figures, the former is useless in two of them. Still, the fact stands, that, in all figures, EA, and even EI, are good premises.

II. The figures differ widely, in respect of the range of their conclusions.

(1.) The pre-eminent power of the First Figure is shown in two features. It is the only figure in which we can prove a universal

Doctrine of
inference.
The special
rules of the
four fi-
gures.

86. These twenty-four valid Moods in Figure are easily ascertained, through application of the six universal rules of the syllogism to those modifications of the functions of the terms in premises, which severally constitute the four syllogistic figures. The limitations which the six rules impose on the character, both qualitative and quantitative, of the propositions admissible to constitute a syllogism in each of the figures, might be gathered from the table, just set down, of the moods in figure. But some uses are served by the generalizing of those limitations into Special Rules of the Figures, and by a brief deduction of these from the six universal rules.¹

Figure I.

The three special rules of the First Figure have already been proved through the dictum. They are proveable, also, through the canons and the deduced universal rules; not with so close a reference to principles, but much more briefly than in the other way.

(1.) The Minor premise must be Affirmative. Suppose it negative: the major premise must then, by the sixth rule, be affirmative; and the major term, being its predicate, will be undistributed. But, by the fifth rule, the conclusion must be negative, and will accordingly have its predicate, the major term, distributed. Therefore, a breach of this special rule would cause the incurable fallacy of an illicit process of the major.

(2.) The Major premise must be Universal. Let it be particular; in other words, let its subject, the middle term, be undistributed. By the special rule just proved, the minor premise must be affirmative, and will not distribute its predicate, the middle term. Therefore, a breach of this rule produces the incurable fallacy of undistributed middle.

(3.) The Quality of the major premise determines the quality of the conclusion; the Quantity of the minor premise limits the quantity of the conclusion. (1.) If the major premise were negative, and the conclusion affirmative, the fifth rule would be violated: if the minor premise were affirmative, and the conclusion negative, then (besides the qualitative fallacy caused by the two affirmative premises), the major, being predicate of both propositions, would suffer illicit process. (2.) The minor term, being subject both of the minor premise and of the conclusion, would suffer illicit process if it were undistributed in the former, and distributed in the latter. If the minor premise is universal, the conclusion may be so: and subalternation would thence yield a particular.

Figure II.

The special rules of the Second Figure are three.

affirmative; and it is the only figure in which we can prove conclusions having all the four forms, A, E, I, and O.

(2.) The Second Figure allows no conclusions but negatives.

(3.) The Third Figure allows no conclusions but particulars.

(4.) While the Fourth Figure allows all forms of conclusion except A, its weakness is shown by this fact, among others: that in it we can prove an I only, from the same premises which, by being merely transposed, would fall into the first figure, and give a conclusion in A.

III. The several pairs of premises are very unequally applicable to the proof of conclusions belonging to the four several kinds. The data sufficient for establishing propositions Particular, or Negative, are, in a humbling degree, more various than those that are required for establishing Universals, or Affirmatives. The five subalternated conclusions being thrown out of account, the reckoning for the other nineteen stands as follows:—

(1.) The moods proving universal conclusions are five; those proving particulars are fourteen.

(2.) The moods proving affirmatives are seven; those proving negatives are twelve.

(3.) A is proveable by one mood; E by four moods; I by six; and O by eight.

¹ Among the neatest demonstrations of the Special Rules of Figure from the six rules, are those of Huyshé. The third rule of the first figure is not given in the English books.

(1.) One of the Premises must be Negative. The middle term, being the predicate of both premises, would be twice undistributed if both were affirmative. The Doctrine of inference.

(2.) The Conclusion must be Negative. One of the premises being negative, the conclusion also must be so, by the fifth rule.

(3.) The Major premise must be Universal. It must be so on pain of illicit process of the major term. The conclusion, being negative, distributes that term: consequently, it must be distributed in its premise, of which it is the subject.

Figure III.

The special rules of the Third Figure are two.

(1.) The Minor premise must be Affirmative. If it were negative, the major premise must, by the sixth rule, be affirmative, and would not distribute its predicate, the major term. But, by the fifth rule, the conclusion must be negative, by reason of the negative premise: consequently, the major term would here be distributed; in other words, there would be committed an illicit process of the major.

(2.) The Conclusion must be Particular. By the rule just proved, the minor premise is affirmative; and the minor term, being its predicate, is undistributed: consequently, if that term were distributed in the conclusion, there would be an illicit process of the minor.

Figure IV.

The awkwardness of the Fourth Figure is never more striking, than when the attempt is made to lay down special rules for its construction. The three following are the most comprehensive of those that have been applied to it:—

(1.) If the Major premise is Affirmative, the Minor premise must be Universal. The middle term, being the predicate of the major premise, is undistributed when that premise is affirmative. If, then, the minor premise were particular, the middle, being subject, would be again undistributed. The rule must be obeyed, for the avoidance of undistributed middle.

(2.) If one premise is Negative, the Major premise must be Universal. If the major premise were particular, the major term, being its subject, would be undistributed. But, by the hypothesis and the fifth rule, the conclusion must be negative, and the major term must there be distributed. The penalty for breach of the rule is illicit process of the major.

(3.) If the Minor premise is Affirmative, the Conclusion must be Particular. The minor term, being predicate of its premise, is, by the hypothesis, undistributed: consequently, it cannot be distributed in the conclusion. The rule is fenced by illicit process of the minor. It is this limitation that makes premises in AA so much less valuable in this figure, than they are when transposed into the first, where the term which was subject of the conclusion becomes predicate, and is, therefore, left undistributed without harm.¹

87. Those logicians who maintain the pre-eminent validity of the first figure, describe syllogisms in it as Perfect and Direct; syllogisms in the other three figures as Imperfect and Indirect.² All syllogisms of the indirect figures The reduction of syllogisms.

¹ These are the rules of the Fourth Figure assigned in the Port-Royal Logic, and by several of the German logicians, as Höffbauer and Bachmann. Huyshé's rules are these three: 1. The Major premise must not be O, else there is an illicit process of the major; 2. The Minor premise must not be O, else there is an undistributed middle; 3. The Conclusion must not be A, else there is an illicit process of the minor.

² In some of the more complex of the old systems, the name of "Indirect" is given to certain moods, of which there are not here recognized any, except such as slip in under the disguise of the

Doctrine of admit of being transformed into syllogisms of the first inference. figure. The process of transformation is called Reduction.

The method which must chiefly be available is evidently the conversion of one or both of the premises. In reducing from the second figure, where the middle term has already its right place in the minor premise, the conversion of the major premise would seem to be sufficient. For the third figure we should require conversion of the minor premise; for the fourth figure, conversion of both.

But, conversion having been performed, we should sometimes have gained premises which, though good in the given figure, are not so in the first. Thus AE, valid data in the second figure, would, in the first, yield an illicit process of the major. EA, however, are good premises in the first figure: therefore the remedy is found in the transposition of the premises, which, also, in some cases, supersedes conversion of them.

Finally, if the premises are transposed, the major and minor terms have exchanged functions. Effect must be given to this exchange by the conversion of the conclusion.

There are required, accordingly, for reduction, all the three methods: conversion of one or both premises, as a step to be taken almost always; transposition of the premises, when they would otherwise be bad; conversion of the conclusion, when the premises have been transposed.

The conclusion of the given indirect syllogism, when it has not been converted in the reduction, is proved directly by the new syllogism in the first figure. If it has been converted, there is proved, in the new syllogism, a conclusion from which the given one may be inferred by re-conversion.

With these alternatives open, reduction is possible and easy for all the indirect moods except two; AOO in the second figure, OAO in the third. The difficulty with these lies in the impossibility of directly converting O. The obstacle may be cleared away through contraposition. But an indirect reduction of another kind is also available.

The Rules of Reduction for all the indirect moods, and the relations between them and the moods of the first figure, were abbreviated by the schoolmen into clumsy names, in which certain of the letters have conventional meanings. For further aid to the memory, the names were cast into five halting hexameters, in several readings, of which the following is one:—

- I. *bArbArA, cElArEnt, prima, dArII, fErIOque*;
- II. *cEsArE, cAmEstrEs, fEsInO, bArOcO, secunde*;
- III. *tertia dArAptI, dIsAmIs, dAtIsI, fElAptOn,*
fErIsO, bOcArO, habet: quarta insuper addit
- IV. *brAmAntIp, cAmEnEs, dImArIs, fEsApO, frEsIsOn.*

Of the twenty-four valid moods in figure, the scheme rejects the five which have subalternated conclusions; and these, when they have to be referred to, may be described as Nameless Moods. The Named Moods, denoted by the leading words in the verses, are thus nineteen.

The First Figure has four named moods. Its admissible number of six is completed by two nameless moods, AAI and EAO, whose conclusions are severally subalternated from those of *Barbara* and *Celarent*.

The Second Figure has four named moods. It has two nameless moods, EAO, and AEO, standing respectively under *Cesare* and *Camestres*.

The Third Figure has six named moods. Its conclusions, being all particulars, cannot have subalternates.

The Fourth Figure has five named moods. Its one nameless mood is AEO, under *Camenes*.

fourth figure. The received moods yield to them the premises without change, and the conclusion by conversion.

The names given to the moods in the "Barbara" lines signify the rules of reduction in this way:—The vowels mark, self-evidently, the quantity and quality of the propositions constituting each mood. Of the consonants, those only are significant which are printed in italics. (1.) The *b, c, d,* and *f,* the initial letters of the four names in figure first, are the only initials used for any of the other names. An indirect mood is thus signified to be reducible to that direct mood, whose name begins with the same letter. (2.) The other significant consonants are four: *s* directs Simple Conversion; *p* Conversion *per accidens*; *m* Transposition of Premises (*metathesis* or *mutatio*); *c* Reduction through Contradiction. The proposition to be operated on through *s, p,* or *c,* is that which is symbolized by the vowel immediately preceding the consonant: the place of *m* in the name is indifferent. The process of reduction is illustrated in the second of the annexed notes.

NOTE I.

EXAMPLES OF THE NINETEEN NAMED MOODS.

Each of the moods is here exemplified twice: first, by a formula framed with symbolic terms, each of which receives the signature of quantity; next, by an argument in significant terms. The matter of all the arguments is gathered from the Preface to Bishop Butler's *Sermons*. There might have been found, probably, apter instances than several of them; but brevity of expression has had to be studied.

FIGURE I.

1. *Barbara*.

A. All M's—are—some P's.

A. All S's—are—some M's.

∴ A. All S's—are—some P's.

A. All beings who on reflection approve virtue—are—beings conscious of obligation to act virtuously.

A. All men—are—beings who on reflection approve virtue.

∴ A. All men—are—beings conscious of obligation to act virtuously.

2. *Celarent*.

E. Any M's—are not—any P's.

A. All S's—are—some M's.

∴ E. Any S's—are not—any P's.

E. Beings conscious of law—are not—beings entitled to disobey law.

A. All men—are—beings conscious of law.

∴ E. Men—are not—beings entitled to disobey law.

3. *Darii*.

A. All M's—are—some P's.

I. Some S's—are—some M's.

∴ I. Some S's—are—some P's.

A. All beings conscious of law—are—beings liable to punishment.

I. Some living creatures—are—beings conscious of law.

∴ I. Some living creatures—are—beings liable to punishment.

4. *Ferio*.

E. Any M's—are not—any P's.

I. Some S's—are—some M's.

∴ O. Some S's—are not—any P's.

E. Beings conscious of law—are not—beings exempt from punishment.

I. Some living creatures—are—beings conscious of law.

∴ O. Some living creatures—are not—beings exempt from punishment.

FIGURE II.

1. *Cesare*.

E. Any P's—are not—any M's.

A. All S's—are—some M's.

∴ E. Any S's—are not—any P's.

E. Parts wanting mutual relation—are not—means conducing to one end.

A. All parts of a system—are—means conducing to one end.

∴ E. Parts of a system—are not—parts wanting mutual relation.

2. *Camestres*.

A. All P's—are—some M's.

E. Any S's—are not—any M's.

∴ E. Any S's—are not—any P's.

Doctrine of inference. A. All parts of a system—are—means conducing to one end.
E. Parts wanting mutual relation—are not—means conducing to one end.
∴ E. Parts wanting mutual relation—are not—Parts of a system.

3. *Festino*.

E. Any P's—are not—any M's.
I. Some S's—are—some M's.
∴ O. Some S's—are not—any P's.
E. Parts of a system—are not—things without a bearing on one design.
I. Some parts of a whole—are—things without a bearing on one design.
∴ O. Some parts of a whole—are not—parts of a system.

4. *Baroco*.

A. All P's—are—some M's.
O. Some S's—are not—any M's.
∴ O. Some S's—are not—any P's.
A. All systems—are—things presupposing mutual relation of parts.
O. Some wholes—are not—things presupposing mutual relation of parts.
∴ O. Some wholes—are not—systems.

FIGURE III.

1. *Darapti*.

A. All M's—are—some P's.
A. All M's—are—some S's.
∴ I. Some S's—are—some P's.
A. All beings obeying the supreme law of their nature—are—beings acting rightly.
A. All beings obeying the supreme law of their nature—are—beings acting naturally.
∴ I. Some beings acting naturally—are—beings acting rightly.

2. *Disamis*.

I. Some M's—are—some P's.
A. All M's—are—some S's.
∴ I. Some S's—are—some P's.
I. Some laws of being—are—laws of supreme obligation.
A. All laws of being—are—laws sanctioned by a penalty.
∴ I. Some laws sanctioned by a penalty—are—laws of supreme obligation.

3. *Datisi*.

A. All M's—are—some P's.
I. Some M's—are—some S's.
∴ I. Some S's—are—some P's.
A. All judgments of reflection—are—laws superior in obligation to mere propensions.
I. Some judgments of reflection—are—judgments of conscience.
∴ I. Some judgments of conscience—are—laws superior in obligation to mere propensions.

(The truth asserted in the minor premise might have been alleged in I². The conversion of the I² into A would throw the argument into the First Figure, and justify a conclusion in A.)

4. *Felapton*.

E. Any M's—are not—any P's.
A. All M's—are—some S's.
∴ O. Some S's—are not—any P's.
E. Judgments of conscience—are not—laws affecting the individual only.
A. All judgments of conscience—are—judgments of reflection.
∴ O. Some judgments of reflection—are not—laws affecting the individual only.

5. *Feriso*.

E. Any M's—are not—any P's.
I. Some M's—are—some S's.
∴ O. Some S's—are not—any P's.
E. Beings obeying laws of their nature—are not—beings acting unnaturally.
I. Some beings obeying laws of their nature—are—beings acting rightly.
∴ O. Some beings acting rightly—are not—beings acting unnaturally.

(Here, again, the datum of the minor premise would justify an I², and enable us to reach, in the First Figure, a conclusion in E.)

6. *Bocardo*.

O. Some M's—are not—any P's.
A. All M's—are—some S's.
∴ O. Some S's—are not—any P's.
O. Some beings obeying laws of their nature—are not—beings acting rightly.
A. All beings obeying laws of their nature—are—beings acting naturally.
∴ O. Some beings acting naturally—are not—beings acting rightly.

FIGURE IV.

(The examples in this Figure are purposely constructed with materials already used for the First).

1. *Bramantip*.

A. All P's—are—some M's.
A. All M's—are—some S's.
∴ I. Some S's—are—some P's.
(The Premises justify the conclusion, in I², "Some S's—are—all P's." See, in the next note, the last of the paragraphs dealing with this mood.)
A. All men—are—beings who approve virtue.
A. All beings who approve virtue—are—beings conscious of obligation to virtue.
∴ I. Some beings conscious of obligation to virtue—are—men.

2. *Camenec*.

A. All P's—are—some M's.
E. Any M's—are not—any S's.
∴ E. Any S's—are not—any P's.
A. All men—are—beings conscious of law.
E. Beings conscious of law—are not—beings entitled to disobey law.
∴ E. Beings entitled to disobey law—are not—men.

3. *Dimaris*.

I. Some P's—are—some M's.
A. All M's—are—some S's.
∴ I. Some S's—are—some P's.
I. Some living creatures—are—beings conscious of law.
A. All beings conscious of law—are—beings liable to punishment.
∴ I. Some beings liable to punishment—are—living creatures.

4. *Fesapo*.

E. Any P's—are not—any M's.
A. All M's—are—some S's.
∴ O. Some S's—are not—any P's.
E. Beings exempt from punishment—are not—beings conscious of law.
A. All beings conscious of law—are—living creatures.
∴ O. Some living creatures—are not—beings exempt from punishment.

5. *Fresiso*.

E. Any P's—are not—any M's.
I. Some M's—are—some S's.
∴ O. Some S's—are not—any P's.
E. Beings exempt from punishment—are not—beings conscious of law.
I. Some beings conscious of law—are—living creatures.
∴ O. Some living creatures—are not—beings exempt from punishment.

NOTE II.

ILLUSTRATIONS OF SYLLOGISTIC REDUCTION.

1. *Extensive or Direct Reduction*.

1. The application of all the rules, except that indicated for two of the moods by c, is obvious and easy. A very few moods will suffice as examples.

FIGURE II.

The structure of this figure is such, that conversion of its major premise throws it into Figure first. That premise, being for Cesare an E, may be converted simply. We thus gain premises which, continuing to be in EA, are good for proving, in Celarent, the E of the *reducens*.

Cesare	Reduced to	Celarent.
The P's—are not—any M's—E.	The M's—are not—any P's—E.	
All the S's—are—some M's—A.	All the S's—are—some M's—A.	
∴ The S's—are not—any P's—E.	∴ The S's—are not—any P's—E.	

Camestres, similarly, would fall into Figure first, if the major premise were converted. But, that premise being an A, its converse would be an I; and the resulting mood would be IE, involving illicit process of the major. If, however, the given pre-

Doctrine of inference.

Doctrine of mises are transposed, they become EA; and the premise which is inference. now the major admits simple conversion into E. The conversion being performed, we have EA, the premises of Celarent. But the terms of the given conclusion have in these premises exchanged functions: therefore, our new conclusion must be the converse of the given one; and the new conclusion may be an E. The process, in fact, is equivalent to the transforming of Camestres into Cesare, followed by the reduction of Cesare to Celarent.

Camestres	Reduced to	Celarent.
All the P's—are—some M's—A. The S's—are not—any M's—E. ∴ The S's—are not—any P's—E.		The M's—are not—any S's—E. All the P's—are—some M's—A. ∴ The P's—are not—any S's—E.

FIGURE III.

Disamis is in the same predicament with Camestres; only that, the Figure being the third, the premise which would suggest itself for conversion is the minor. There would emerge bad premises in II. The remedy is found by reversing the premises, converting the I which has thus become the minor, and giving effect to the reversal by conversion of the given conclusion. The same result would follow, if Datisi were first formed from the given Disamis, and then reduced to Darii by simple conversion of the minor premise.

Disamis	Reduced to	Darii.
Some M's—are—some P's—I. All M's—are—some S's—A. ∴ Some S's—are—some P's—I.		All M's—are—some S's—A. Some P's—are—some M's—I. ∴ Some P's—are—some S's—I.

FIGURE IV.

Fresison has premises which, by simple conversion of both, become EI in Figure first. Therefore it is manageable by this, the process which would naturally be first thought of.

Fresison	Reduced to	Ferio.
The P's—are not—any M's—E. Some M's—are—some S's—I. ∴ Some S's—are not—any P's—O.		The M's—are not—any P's—E. Some M's—are—some M's—I. ∴ Some S's—are not—any P's—O.

Camenes, on the other hand, if so treated, would give premises in II, yielding no conclusion. But Figure first would be gained, also, by transposition of the premises, which would then be those of Celarent. This, with the consequent conversion of the conclusion, is the method ordered.

Camenes	Reduced to	Celarent.
All P's—are—some M's—A. The M's—are not—any S's—E. ∴ The S's—are not—any P's—E.		The M's—are not—any S's—E. All P's—are—some M's—A. ∴ The P's—are not—any S's—E.

Those old logicians, who framed the name Bramantip, followed Boethius in admitting, under the name of Conversion *per accidens*, all conversions in which the *matter* allowed change of quantity, whether by particularizing or by universalizing. When we admit, as we should, no conversions but such as are correct formally, the name is deceptive: its *p* orders an operation which is impracticable. If the given conclusion is to be dealt with at one sweep, what has to be done is the conversion of I, illogically, into A. The rationale of the process (in the more obvious view of it) is this:—The premises, being transposed, become AA in Figure first. They yield, in the nameless mood AAI, a conclusion which is the simple converse of the given one. But they yield also, in Barbara, a conclusion in A. We may adopt the conclusion in A, not as holding it to be a good converse of our I, but because it follows from the premises. We do adopt it, in obedience to the principle of the scheme, that of always inferring, from premises, the widest conclusion they permit. If we still wish for the I, we may earn it lawfully by subalternation from the A.

Bramantip	Reduced to	Barbara (or AAI).
All P's—are—some M's—A. All M's—are—some S's—A. ∴ Some S's—are—some P's—I.		All M's—are—some S's—A. All P's—are—some M's—A. ∴ All P's—are—some S's—A. (∴ Some P's—are—some S's—I.)

But Bramantip should be looked into more closely. Its premises justify a conclusion, not in I merely, but in I²: "Some S's—are— all P's." The simple converse of this is, "All P's—are—some S's," being the A which we have just gained in Barbara. When we conclude in I from the premises of this mood, we are really inferring a subalternate of the conclusion to which we were entitled. Bramantip, however, is the only mood of the nineteen, the analysis of which requires, for its completion, any propositional form besides the received four.

2. Indirect Reduction.

2. The moods Baroco and Bocardo are, in the syllogistic doctrine, the *crux logicorum*. Their inflexibility arises from the double occurrence of O. The character of the conclusion compels us to look for reduction into Ferio; and this mood is not approachable through any of the methods *s, p, m*.

Those who named the two unmanageable moods, were logicians who refused to allow the conversion of O through contraposition. On this footing, it is impossible to transform either of the two into any other syllogism that shall yield, either the given conclusion, or an equivalent of it. We cannot, in the first figure, prove, from the data, that the given conclusion must be true if the premises are so. In short, that which is called ostensive reduction is impossible. But the syllogism may be reduced indirectly. We can prove, not properly in, but only through, the First Figure, that, if the premises are true, the given conclusion cannot be false.

This manner of arguing is founded on the doctrine of contradictory propositions; the two which come into play being O and A, the given conclusion and its contradictory. It is proved that, if the premises of the given syllogism are assumed to be true, the A must be false: whence, by the rule of contradictories, it is inferred that the O must be true. The only assumptions required are two, which are involved in the nature of all inference: first, that the premises of a syllogism are admitted, or are assumed to be true; secondly, that, if the conclusion of a valid syllogism be false, one or both of the premises must be false. The process of which these are the principles is called Indirect Reduction—Reduction *ad impossibile* or *absurdum*, or *ex impossibili* or *absurdo*.

The steps are the following:—The premise denoted by the vowel preceding the *c* is thrown aside; and there is substituted for it the contradictory of the given conclusion. From this new premise (an A), and the retained premise (another A), there is inferred an A in Barbara. The reduction is thus completed, according to the rules symbolized in the name.—But, if we stop here, we have proved nothing to the purpose. Our new conclusion in A has not even the same terms with the given conclusion in O. We have promoted our given middle term to the rank of major in dealing with Baroco, to that of minor in dealing with Bocardo. In effect, the syllogism in Barbara has merely supplied one datum for a process of inference through contradiction, in which the essential part of the operation lies.

The A which is the conclusion in Barbara is found, on comparison, to be the contradictory of the O which was the premise elided from the given syllogism. But this O, as a datum, must be assumed to be true: therefore the A must be false. Now, the A has been inferred validly from its premises: therefore, one or both of these must be false. The premise borrowed from the given syllogism must, as a datum, be true: therefore the falsity must lie in the premise which we constructed for ourselves. But this premise is the contradictory of our given conclusion; and, the contradictory being false (having been proved to be inconsistent with the original data), the given conclusion must be true. Q. E. D.

Baroco	Reduced to	Barbara.
All P's—are—some M's—A. Some S's—are not—any M's—O. ∴ Some S's—are not—any P's—O.		All P's—are—some M's—A. All S's—are—some P's—A. ∴ All S's—are—some M's—A.

A, the conclusion in Barbara, is the contradictory of O, the rejected premise in Baroco: the O being assumed as true, the A must be false. Consequently, one or both of the premises of the Barbara must be false. Its major premise must be assumed as true, having been a premise in the given Baroco: therefore the minor premise must be false. But this minor premise is the contradictory of the given conclusion: therefore the given conclusion must be true.

Bocardo	Reduced to	Barbara.
Some M's—are not—any P's—O. All M's—are—some S's—A. ∴ Some S's—are not—any P's—O.		All S's—are—some P's—A. All M's—are—some P's—A. ∴ All M's—are—some S's—A.

The subsequent inferences proceed, step by step, as for Baroco.

3. The demonstration that a proposed conclusion must be true, because it is impossible that it can be false, is not only always cumbrous, but also, in many instances, slow in generating conviction. It is never used, by logicians or by others, when it can be escaped from. Yet it is of common use and very wide application. Even axioms, whether popular or philosophical, may have their meaning, if not their truth, brought out more clearly, when it is shown that the denial of them must lead to consequences which are absurd. In controversy, demonstration through impossibility lies at the root of the argument *ad hominem*: an opponent denying a conclusion of ours, we endeavour to prove that his denial is contradictory of propositions which he himself admits. In geometry, indirect demonstration is familiar; and the name, *Reductio ad absurdum*, which mathematicians are wont to give it, comes from its syllogistic application, and is needlessly retained when reduction is not aimed at.

It may be worth while to observe two points of difference, between the logical uses of indirect demonstration on the one hand, and the scientific and popular uses of it on the other.

First, In the search for propositions whose truth is inconsistent with the falsity of a proposition to be proved, an expounder of the

Doctrine of inference. exact sciences has before him a field of choice broadening with every truth he has already been able to prove. The impossibility of the falsehood of a theorem is demonstrable through the inconsistency of the falsehood with any of the truths which, whether as axioms or as propositions proved, have previously received a place in the system. Even in questions involving contingent truths the position of a reasoner is not dissimilar to this.—Contrariwise, in the indirect reduction of a syllogism, the logician can assume nothing except his two premises. But, as we have learned, nothing else is necessary. The logical procedure is, in fact, with the one exception of its working towards the first figure, the very same process which is and must be followed, in all demonstrations through contradiction. The search for data is only a gathering of the materials, out of which is woven a chain of reasoning, every link of which depends on the law of contradiction, and is transmutable into the strictest logical forms.

Secondly, In mathematics always, in other kinds of matter not seldom, the inconsistency founded on lies between propositions logically describable, not as contradictories, but only as contraries: that is, it lies between E and A. Why, it may be asked, is this sufficient? For plain reasons, indicating very frequent cases. In the first place, contraries cannot both be true: if we can hold the one to be true, we may infer the falsity of the other. Again, in the exact sciences, it is evident that no propositions are particular: all are either universal or singular. Therefore the law of contradiction presses from all sides on the contraries, with the same force as on contradictories when they are possible. This remark might be stretched very far indeed beyond the bounds of the sciences treating number and quantity. All philosophical doctrines, whether of mind or of matter, are strictly universals. But the illustration of this point would lead us much out of our way.

3. Reduction through Contraposition.

4. Contraposition, and Conversion of the Contraposita, being allowed for O and A, Baroco and Bocardo may be reduced directly or ostensively.

The principle of the process appears most clearly, when we suppose the contraposition to be first completed, to the effect of throwing the syllogism into another mood in the same figure. In the second figure, our negative conclusion must be retained: therefore, for Baroco, we must transform the AO of the premises into EI. The syllogism thus passes into Festino. Indeed, in framing a syllogism from given materials, it is often a matter of indifference which of these two moods we throw it into. The relation between Baroco and Festino is paralleled, in the third figure, by that between Bocardo and Disamis: the transformation is here effected by transforming each of the O's into an I. The syllogisms thus framed, in Festino and Disamis, are then subject to the ordinary rules of Ostensive Reduction.

Some of the logicians who admit this method, have emulated the schoolmen in the fabrication of names, designed to intimate, like the old ones, the manner of performing the process at one step. In these names, the *c* denotes conversion, through contraposition, of the preceding proposition: *m* denotes transposition of premises as before. In this way, Baroco is represented by Facoro, and Bocardo by Docamo. But these names, though adopted by Whately, fail to point out all the steps. If we must have names, exactness would require such as these still more whimsical ones—Facoco, Docamoc.

Baroco, thus treated, gives a syllogism in Ferio, proving the given conclusion. Bocardo gives a syllogism in Darii, proving the converse of the contraposita of the given conclusion.

The reduction, whether taken at one step or in two, requires no illustration beyond the examples.

BAROCO—Reduced (through Festino) to—FERIO.

1. Baroco.

All P's—are—some M's—A. The P's—are not—any things—not M's—E.
Some S's—are not—any M's—O. Some S's—are not—any things—not M's—E.
∴ Some S's—are not—any P's—O. ∴ Some S's—are not—any P's—O.

2. Festino.

The P's—are not—any things—not M's—E.
Some S's—are not—any things—not M's—E.
∴ Some S's—are not—any P's—O.

3. Ferio.

Things not M's—are not—any P's—E.
Some S's—are—some things not M's—I.
∴ Some S's—are not—any P's—O.

BOCARDO—Reduced (through Disamis) to—DARII.

1. Bocardo.

Some M's—are not—any P's—O. Some M's—are—some things not P's—I.
All M's—are—some S's—A. All M's—are—some S's—A.
∴ Some S's—are not—any P's—O. ∴ Some S's—are—some things not P's—I.

2. Disamis.

Some M's—are—some things not P's—I.
All M's—are—some S's—A.
∴ Some S's—are—some things not P's—I.

3. Darii.

All M's—are—some S's—A.
Some things not P's—are—some M's—I.
∴ Some things not P's—are—some S's—I.
∴ Some S's—are—some things not P's—I.
∴ Some S's—are not—any P's—O.

4. Wider Applicabilities of Reduction.

5. If the Reduction of syllogisms were merely a game to be played at (and sometimes it has been elaborated till the practical sinks out of sight), the ball might evidently be tossed from any of the four quarters of the field, and pass from any one hand into any other. It would be difficult to exhaust, for any given syllogism, the possibilities of metamorphosis through such operations as the rules of reduction allow.

In transferring imperfect syllogisms to the first figure, the quality of the propositions would raise no very strong barrier between the affirmative moods and the negative: the quantity of the terms would fix the only peremptory limit. Reduction *ex impossibili* is as apt, and as easy, for any other moods, as for the two which have a monopoly of it; although, for some of them, we should have to be content with arguing from the contrary instead of the contradictory. Further, moods of any figure might be changed into moods of any other.

The scrutiny of syllogisms for such purposes as this, does, in more instances than one, point to curious relations between moods, all of them traceable ultimately to the fundamental laws. The inquiry might be made, in logical teaching, a useful discipline of sagacity and exactness; and it might also draw the study of the syllogism away from that mechanical reliance on rules, into which the very symmetry and completeness of the scholastic system are apt to make it degenerate.

But the results have no claim to reception in an outline of logical science.

DIVISION II.—THE SYLLOGISM ANALYSED IN EXTENSION AND COMPREHENSION.

88. If we were to be content with possessing a set of The bearing of the wholes of predication on the structure of the syllogism. rules enabling us to test, easily and infallibly, the conclusiveness of every argument that could be proposed, the syllogism would have been dissected deeply enough, when it had yielded the two canons, and the corollaries flowing from them. Differences of figure would have no importance: the process of reduction and its principle might, with equal safety, have been left unexamined. If, again, seeking for a higher law, we still aimed only at forcing the indirect moods into the precinct over which the *dictum* bears sway, the end would have been attained when the study of the scholastic scheme had put it in our power to transform every imperfect syllogism into one of the perfect forms which are to be found in the first figure.

But, while the canons, and the rules of reduction, have each a substantive logical value, the syllogism is most incompletely understood, if it is studied only through either of those media, or even through both. The former, taken alone, would leave us where we should be left, in biological science, if we had qualified ourselves only for distinguishing and describing a part of the animal body, without having learned anything as to the physiological relations between the given object and others. By the latter method, on the other hand, we should, indeed, begin the study of functions; but we should drop it before having gone further than the collection of data: our position would be that of the anatomist, who, after having microscopically determined the structure of the animal tissues, should refrain from asking how that structure affects the action of the organs which the tissues constitute.

Reasoning through common terms has pre-formed classifications as its data. It is merely an explication, an evolution into the form of judgments and propositions, of relations implied in a presupposed ordination of the concepts and terms.

What the ordination is, that is presupposed in a given process of mediate inference, we ascertain at a glance when the syllogism is in the first figure. In that figure we infer, in regular descent of extension, from term containing to term contained; from the major, through the middle, to the minor. This order of the terms is necessarily, for the first figure, the order of extension assumed in the pre-formed series of terms. The order of comprehension is, of course, that order reversed.

Doctrine of inference.

Doctrine of inference. What the presupposed ordination of terms is, in a syllogism in any of the indirect moods, is learned through the relation of that mood to a mood in the first figure. That relation has been exhibited to us, for all the indirect moods, in the Rules of Reduction. Though reduction should in itself be held worthless, its rules are invaluable, as facilitating progress to something beyond them. They are premises, regularly and completely arranged, from which may be inferred, more easily by far than if we wanted them, the true relations of the several syllogistic figures, the truths in virtue of which each of the figures has a place, though not all a place equally high, in the actual system of human intelligence.

The rules bridge over, for occasional passage, the gap which yawns between the first figure and the others. Where their foundations are dug into, modes of thought are laid bare, which unite all the figures into one symmetrical formation.¹

¹ The principle which it is here attempted to bring to bear on the syllogism, is that whose positive applicability to such a use may fairly be said to have been undreamt of till it was declared by Sir William Hamilton, and which has hitherto been so applied by him alone. (See Note to Section 33.) Those students of the science (and they do seem to be as yet few) who, in their inspection of Hamilton's logical system, have advanced, from his doctrine of quantification, to this deeper-lying section of his theory, will perceive already, that the purpose for which the principle is here used is different from his;—if, indeed, those scanty notices, which only have hitherto been made public, entitle us to judge precisely as to his views of the ultimate bearing of the principle.

Both in the *New Analytic*, and in Hamilton's own Appendix to the *Discussions*, the point which comes out most prominently is, the reducibility of all the three receivable syllogistic figures under one law. The characteristic differences of the three figures, as traceable to the wholes in which their propositions severally predicate, are, indeed, exhibited to demonstration; but reduction of the second and third figures to the first seems to be condemned, as a process both needless and unscientific. The opinion which has forced itself on the present writer is this: that the first figure, as founded on the ordained hierarchy of the three terms, while the others are not so, must retain its Aristotelic pre-eminence; that the functions of the other figures, as expressions for processes of thought, do not appear clearly unless through comparison with the first figure; that reduction by the common rules gives the only means of such a comparison; and that the view here taken of conversion, as a transference of predication from whole to whole, reconciles reduction completely to the true theory of the relation between extension and comprehension.

Trendelenburg, it was already observed, asserts peremptorily the necessity for considering both wholes, if we are to have a philosophical theory of the syllogism. But he treats the question quite generally, and also (it may rightly be said) no more than negatively. Even here, he stands much closer to Schleiermacher than to Hamilton. He maintains the insufficiency of the analysis in extension: but, taking his position as an out-and-out adversary of the Formal Logic, he abstains from all attempts at positive application of the principle to the formal syllogistic scheme. Indeed, his comparison of the wholes leads him, at once, on to that objective ground, on which he aspires to founding logical science. That the distance between his point of view and Hamilton's may be the more clearly seen, there are here set down, from his *Logische Untersuchungen* (sect. xvi., vol. ii.), a few of those passages in which his opinions appear with the smallest admixture of the metaphysical element.

After having observed that the usual form of the "Dictum" contemplates extension, and that the "Nota notæ" contemplates comprehension, he proceeds thus: "The syllogism emerges out of the reciprocal reference of comprehension and extension. If the comprehension of a concept (the positive or negative law) is applied to its extension, there arises the *categorical* syllogism. The comprehension (major term) of a concept (middle term) governs its extension (any of the species, minor term). If, on the other hand, the same law is expressed for all the species, and if, out of this content (or comprehension) of the extension, the comprehension of the containing universal is collected, there arises the *disjunctive* syllogism. The species constitute the middle term, or concept, whose comprehension becomes the comprehension of the genus." (Pp. 239, 240). . . . "Comprehension and extension, in the relation of Law and Phenomenon, constitute the essential elements (*Seiten*) of the concept; and their reciprocal relation constitutes

89. Two preliminary points require to be considered, for enabling us to extricate, out of the received syllogistic doctrines, all the relations of the syllogism, both to the extension and to the comprehension of its three terms. The differences in the character of predication between the first figure and the other three.

In the first place, the forms of predication, on the analysis of which the received system rests, are those in which the terms are concrete, not abstract. It is, in fact, all but impossible, as we have already seen, to express intelligibly differences of quantity, when abstract terms are adopted throughout; while, likewise, the union of concrete terms with abstract, both betrays and causes confusion of thought. Concrete terms, however, point directly to predication in extension; and this is one of several reasons why the relation of comprehension has been so much overlooked.

Secondly, the conversion of a proposition is nothing else or more than the transference of predication from the one whole into the other. When this doctrine is called to mind, it becomes evident how thoroughly the relations of the figures to the wholes are implied in the rules of reduction.

These considerations being premised, it is the easiest thing in the world to mark, for all syllogisms whose propositions are either A, E, I, or O, the whole in which every one of the propositions predicates.

Considered without reference to the wholes of predication, the three receivable figures severally exhibit the three terms as formally ordained in this way. In figure first, the middle stands between the minor and the major; in figure second, the middle stands above both of them, the one being predicated in, the other out of it; in figure third, the middle stands below both of them, being predicated in both, or in the one and out of the other. When we have discovered in which of the wholes it is that each of the predications takes place, we have discovered also how it is, that, in the second and third figures, the middle term has come to hold a position different from that which should belong to it, as being the connecting link of thought between the minor and the major.

I. In the first figure, each of the three propositions is a Predication in Extension. The minor term is placed in the extension of the middle, the middle in the extension of the major, or of its contradictory; and, consequently, the minor is placed in the extension of the major, or of its contradictory.

Clearly, too, by converting all the three propositions, we should gain three propositions in comprehension. If, indeed, we are prohibited from adopting any propositional forms except the received four, the syllogism formed must be bad. But if the conversion were made thorough, through additional forms, the new syllogism would not violate, either the law of mediate inference, or any of the common rules. This view, however, is neglected in the books.

its life." (P. 241). . . . "What vouches, then, for the completeness of the forms of the syllogism? The comprehension is referred to the extension; and out of the extension the comprehension is determined, and that both positively and negatively." (P. 248). . . . "Must the syllogism, then, be nothing but a subjective function without a real counterpart? No. The comprehension, representing the law of the extension, contains the possibility of the syllogism; and therein also is its objective value intimated. To the *genetic* universal, which rests on an original community of thought and existence, there corresponds the *quantitative* universal. The necessary ground (reason) hence clothes itself in the expression of a universal fact, and becomes, in this form, the middle concept of an objective syllogism. That which, in the real, is the ground (reason), becomes, in the logical, the middle term of the syllogism. Aristotle himself acutely pointed out this parallelism. (*Analyt. Post.* ii., 2, 11, 12; *De Anima*, ii., 2: compare Trendelenburg's *Elementa Logices Aristotelicae*, § 58, &c.) But the formal logic, which would have nothing to do with the real, allowed this profound suggestion to lie unused." (P. 280).

Doctrine of inference. whole. In a word, the first figure predicates exclusively in one whole.

II. None of the other three figures predicates exclusively in one whole. In each of them, two of the propositions are predications in the one whole; while the third is a predication in the other.

The several indirect moods stand in two several relations to the first figure, indicated respectively by their requiring or not requiring, in reduction, transposition of premises, and consequent conversion of the conclusion. This difference makes it impossible to lay down, for syllogisms expressible through the four received forms of predication, laws systematically distinguishing each of the indirect figures from the others. But an approach is made to such laws in the following statement:—

Figure II.

In *Cesare*, *Festino*, and *Baroco*, the major premise predicates in comprehension; the minor and the conclusion predicate in extension. In *Camestres*, whose premises in this order are bad for the first figure, the major premise predicates in extension; the minor and the conclusion predicate in comprehension. In this figure, for all moods, the whole in which the minor premise predicates, determines the whole predicated in by the conclusion.

Figure III.

In *Darapti*, *Datisi*, *Felapton*, and *Feriso*, the minor premise predicates in comprehension; the major and the conclusion predicate in extension. In *Disamis* and *Bocardo*, whose premises (equivalents through contraposition) are in this order bad for the first figure, the minor premise predicates in extension; the major and the conclusion predicate in comprehension. In this figure, for all moods, the whole in which the major premise predicates, determines the whole for the conclusion.

Figure IV.

In *Bramantip*, *Camenes*, and *Dimaris*, both premises predicate in extension; the conclusion predicates in comprehension. In *Fesapo* and *Fresison*, both premises predicate in comprehension; the conclusion predicates in extension. In the moods whose premises must be transposed to pass into the first figure, the conclusion is in comprehension; in those whose premises do not require transposition, the conclusion is in extension.

The predications of the first figure analysed in extension.

90. The general character of the First Figure has already come out so clearly, as to call, now, for no special explanation.

It is distinctively the form of Deductive Thinking. It presupposes the classification of objects in the progressive order of generalization; and, starting from the widest class, it infers, through a class intermediate, the inclusion of a lowest class within the sphere of the highest.

A principle or law, assumed as already established, is inferred to govern or not to govern a given case, because it is asserted that the given case is included in a class of cases which are known to be governed or not to be governed by the assumed law or principle. The given case S is included in the class of cases M; the whole class of cases M is governed by the law P or Not-P: therefore the case S is governed by the law P or Not-P. Or, otherwise, for negatives, the case S is included in the class of cases M; the whole class of cases M is excluded from the cases governed by the law P: therefore the case S is excluded from the class of cases governed by the law P. The ordination of terms is, always, from most to least extensive, P (or Not-P), M, S.

There thus appears, first of all, the distinction between the two Affirmative moods of the figure, *Barbara* and

Darii, and the two Negative moods, *Celarent* and *Ferio*. Doctrine of inference. The difference arises wholly out of the quality of the assumption made in the major premise. That premise determines the conclusion to affirmation or to negation. When it is affirmative, the inclusion of the terms is direct in all its three steps. When it is negative, the inclusion in the second step, and, consequently, that in the third, may still be held to be a direct inclusion in the contradictory of the major. But the laws of ordination would allow us, also, for negatives, to hold the second step as being an exclusion of co-ordinates (M excluded from the extension of P), and the third step, consequently, as an exclusion of a subordinate from a co-ordinate of its superordinate (S excluded from the extension of P).

Next appears the distinction between the two Universal moods, *Barbara* and *Celarent*, and the two Particular moods, *Darii* and *Ferio*. This difference arises wholly out of the quantity of the subsumption made in the minor premise. According as all of the S's, or only some of them, are placed in the middle term, so all, or only some, are inferred to be in, or out of, the major. The difference may, in effect, be considered as accidental: it arises properly out of our poverty in class-names. The objects designated by our minor term are for us a whole: they are a whole which we are not compelled to regard as constituted by parts: they are our lowest datum, which must pass, through the middle term, into or out of the major, without change or analysis. In this figure, indeed, the minor term may be a singular, without any impinging either on principle or on form. If we give to the minor term the signature "some," this is only because we have not a name narrow enough to yield "all:" we cannot specificate the objects more exactly than by saying, that they are "some" of the objects constituting the class S. If we were to describe them as "All the objects which are called some S's," we should have ground for a universal conclusion: and this suggestion may help to show how these particular moods are really inessential variations of the universal ones.¹

91. The mutual dependence of comprehension and extension makes inference to be possible, though the deductive sequence of the terms is departed from. But the departure imposes limitations, either on the quality of the conclusion or on its quantity.

When the sequence is deserted in the premise which either is the *major* as given, or would be the major if the sequence were obeyed, the conclusion is made *negative*. This is the predicament of the Second Figure. Its characteristic shortcoming, when looked at from the objective side, lies in this. While it asserts, in its lowest step, the minor premise, that S is one of the class of cases M, it does not assert, in the major premise, either that the class of cases M is included under, or excluded from, the operation of the law P. Hence there are no data for affirmation: and it is only indirectly that even negation is justified.

I. The normal character of the figure is exhibited by *Cesare*, and its subalternate mood *Festino*. In the minor premise of these, the foundation is laid for a deductive argument. The minor is placed in the extension of the middle. But there does not follow a major premise, which shall place

The predications of the second figure in both wholes.

¹ This universalizing of the minor term would be useful, also, if we were to attempt expressing *Ferio* in comprehension. It would enable us to dispense altogether with Hamilton's partial negatives. It serves the same use in the second and third figures, for moods which have the conclusion in O. For the universalizing may be used, in the indirect figures, not indeed always for the minor term, but always for the term which would be the minor if the syllogism were reduced to Figure first. *Festino* is thus manageable directly, *Baroco* through it, but not otherwise; *Felapton* and *Feriso* directly. *Bocardo* cannot discard the partial negatives in comprehension, unless by being transformed into the affirmative mood *Disamis*: *Fesapo* is independent of them, without being universalized.

Doctrine of the middle term either in or out of the extension of the inference. major. We turn abruptly round, and predicate in comprehension. The placing of the major in the comprehension of the middle would plainly determine nothing, the middle having in the other premise been considered only in part. Therefore we exclude the major term from the comprehension of the middle.

II. The necessity of transforming *Baroco* into *Festino*, through contraposition, if it is to exhibit the ordination of terms in any workable shape, is prognosticated by its initial step. Its minor premise excludes the minor from the extension of the middle, and thus seems to bar all further progress.

III. *Camestres* is merely *Cesare*, with the premises misplaced, and with the legitimate functions of the minor and major terms consequently interchanged.

The predications of the third figure in both wholes.

92. The position of the Third Figure is this. It deserts the sequence of deduction in its initial step: its *minor* premise, or that which is the minor when the deductive sequence is established, predicates in comprehension. The consequent limitation of the result falls on the quantity: the conclusion is necessarily *particular*.

The root of the restriction lies in the opposite quarter from that which made the second figure negative. The compass of the law P is here definitively fixed, either positively or negatively; but the cases to be placed within the law, or out of it, are assumed as being only a part of S. The reason is, that, in our lowest step, we want the clue to the ordination. We are not able to assert, in our minor premise, that the S's, or any of them, are in the class of cases M: we are able to assert, only, that the cases M, or some of them, possess the attribute S; and, not holding ourselves entitled to aver that they are in exclusive possession of that attribute, we say only that the M's, or some of them, are some of the S's. Accordingly, when, in our major premise, all the M's have been asserted to be under, or free from, the law P, it is only of some of the S's that we can infer the subjection to the law, or freedom from it.

The moods of this figure, when they are examined with reference to the deductive sequence of terms, and the consequent relations to the first figure, are found to fall into three classes. In scrutinising all of these, we must remember that, as a consequence of the imperfection of knowledge implied in the lower of the premises, the minor term must pass through the syllogism unchanged, as "some S's."

I. The character of the figure appears most purely in *Datisi*, and the parallel negative, *Feriso*. The particularity of the minor term being kept in view, the terms appear as rising by steps, each of which is a part only of the higher. Our "some S's" are a part of the class M; the whole class M is a part of the class P (or Not-P): consequently the "some S's" are a part of the class P (or Not-P). The data do not exceed the minimum required for justifying the result.

II. In *Darapti*, and its negative *Felapton*, the data do exceed the minimum; for, though the subsumption is wider than in the first two moods, the conclusion is not so. When all the propositions have been made predications in extension, their import, quantities being fully expressed, is this: "Some S's are all M's; all M's are some P's (or Not-P's): therefore some S's are some P's (or Not-P's)." The class which, for want of a more precise name, we call "some S's," is not, as before, a part of the class M: it is identical with that class, or constitutes the whole of it. The subordination of the minor term to the middle is merely formal; and even the appearance of subordination vanishes when the minor premise is fully converted. The ordination presupposed is not genuine. "Some S's" and "all M's" are equipollent terms, identical both in extension and in comprehension.

III. *Disamis*, and its negative *Bocardo*, are in the same situation as *Camestres*. *Disamis* takes a circuitous path to reach the conclusion of *Datisi*: and *Bocardo*, going still further astray, by starting from a negation in its lower premise, cannot be brought to exhibit the deductive relations of its terms, otherwise than by a process which is equivalent to its passage through *Disamis*.

Doctrine of inference.

93. The rules for reduction exposed the Fourth Figure, as being a deformed variety of the first. Inspection of the wholes of predication at once renders the reason of the rules, and shows the source of the clumsiness.

The five moods fall obviously into two classes, differing diametrically in the character of their deviations from the deductive progress.

The predications of the fourth figure in both wholes.

I. In *Bramantip*, *Camenes*, and *Dimaris*, we have received good premises for *Barbara*, *Celarent*, and *Darii*: and we retain these as predications in extension. But we misplace them; or, without misplacing, we mistake the functions of the major and minor terms. From our premises in extension, we draw, by a sudden inversion, a conclusion in comprehension.

II. In *Fesapo* and *Fresison*, both premises predicate in comprehension. These would yield, also, in comprehension, good conclusions, but only in $\frac{1}{2}E$, unless we were to universalize the minor term. The conclusions which we do infer are predications in extension. *Fesapo*, again, is, in respect of ordination, situated similarly to *Felapton*.

It is plain that, in neither of the classes, does the character of the premises present any feature entitling the figure to be ranked as natural or independent. In the moods of the first class, we have simply misused premises which are good for the first figure, and which are expressed in a form fitting them for convenient use. In the moods of the second class, the difficulty of managing the given predications in comprehension does make it more difficult, but still not impossible, to reach the pure deductive sequence. If the figure had any claim to a place in the legitimate system, it could only be in respect of these two moods, or rather in respect of *Fresison* alone.

94. A Proposition must be a Predication in one Whole. But every proposition may, through conversion, become a predication in the whole opposite to that in which it was given. Consequently, every one of the nineteen or twenty-four syllogisms of the scholastic scheme might be made to assume a new form, by having each of its three propositions converted.

The transformatibility of all syllogisms by exhaustive conversion.

The new syllogisms, however, would correctly represent the old, on this condition only, that the conversion should everywhere be not only safe but exhaustive. Not only must no term be distributed in the converse, which was undistributed in the convertend; but, also, no term must be undistributed in the converse which was distributed in the convertend. Clearly, if this requirement were not complied with, the converted syllogisms might, through failure of distribution, contain fallacies of quantity not committed in the syllogisms from which they had been formed.

The condition, however, cannot be fulfilled through methods of conversion obeying the common rules, or confined to the four propositional forms A, E, I, O.

Ordinary speech, like ordinary thinking, proceeds by preference in the whole of extension: we never do, continuously or systematically, either think or speak in comprehension. The received doctrine of predication, and the syllogistic theory which assumes it, are alike accommodated to this universal tendency. The four propositional forms are designed, and are adequate, to express processes of thought, which are conducted explicitly in extension, comprehension being only silently implied. The mediæval theory of the categorical

Doctrine of
inference.

sylogism, in which the doctrine of predication receives its highest development, takes for granted predication in extension only. Accepting the first figure as the norm, it lays down, indeed, general principles, which are correctly applicable to propositions expressed in either whole: but its whole array of specific rules is worked out on the supposition, that the propositions of that figure predicate in extension, and not otherwise.

In every one of the indirect moods there are, as we have discovered, propositions which, extension being accepted as the form of the first figure, must be interpreted as predications in comprehension, in virtue of that ordination of terms, of which the first figure is an explication. No serious difficulty arises hence, so long as we rest satisfied with treating syllogisms in the scholastic fashion. Almost all those propositions in comprehension, which appear in any of the indirect moods, are expressible in one or another of the four established forms: indeed, the genuine conclusion of *Bramantip* is the only exception. Even though we pass to reduction, those forms are sufficient for exhaustive conversions in all cases, except the minor premises of the three anomalous moods, *Darapti*, *Felapton*, and *Fesapo*.

If, however, we aim at a conversion of *all* the propositions of a syllogism, there is not found, among the fourteen named moods of the three genuine figures, any one for which the A, E, I, O are sufficient. The I² is peremptorily called for as expressing the only thorough converse of A. Even the $\frac{1}{2}$ E, too, would have to be taken as the converse of O if conversion of it were insisted on. This weak form is indeed avoidable, through universalizing of minor terms, for all moods except *Baroco* and *Bocardo*: but for these it is inevitable, unless we hold (as we ought) that they are not directly expressible through conversion.

To a series of syllogisms thus made up almost all the specific rules of the common system would clearly be inapplicable. But it is a test of the soundness of the orthodox system, so far as it goes, that all the principles on which its rules are founded tell on the transformed syllogisms with undeviating exactness.

The predi-
cations of
the first
figure ana-
lyzed in
compre-
hension.

95. The possibility of thus setting forth any syllogism of the common scheme in each of two convertible shapes, is a point of doctrine for which we cannot be too thankful. It is at once a decisive proof, and an instructive illustration, of that theory of the counter-relations connecting the wholes of a concept, without which the laws of the syllogism are left destitute of a firm philosophical foundation.

But nothing of a practical applicability seems to be attainable through the exhaustive transformation of the received moods. It is enough, at all events, for the purpose here in view, that the process be exemplified by exhibition of the forms which the Named Moods of the First Figure put on, through exhaustive conversion of all their propositions.

The premises in extension are here set down in the usual order. For expression of the syllogism in comprehension, they must of course be transposed; since the conversion of the conclusion makes its terms exchange functions.

BARBARA.

1. In Extension.

Major Premise All M's—are—Some P's (A).
Minor Premise All S's—are—Some M's (A).
Conclusion ∴ All S's—are—Some P's (A).

2. In Comprehension.

Major Premise Some M's—are—All S's (I²).
Minor Premise Some P's—are—All M's (I²).
Conclusion ∴ Some P's—are—All S's (I²).

CELARENT.

1. In Extension.

Major Premise Any M's—are not—Any P's (E).
Minor Premise All S's—are—some M's (A).
Conclusion ∴ Any S's—are not—any P's (E).

2. In Comprehension.

Major Premise Some M's—are—all S's (I²).
Minor Premise Any P's—are not—any M's (E).
Conclusion ∴ Any P's—are not—any S's (E).

DARII.

1. In Extension.

Major Premise All M's—are—some P's (A).
Minor Premise Some S's—are—some M's (I).
Conclusion ∴ Some S's—are—some P's (I).

2. In Comprehension.

Major Premise Some M's—are—some S's (I).
Minor Premise Some P's—are—all M's (I²).
Conclusion ∴ Some P's—are—some S's (I).

FERIO.

1. In Extension.

Major Premise Any M's—are not—any P's (E).
Minor Premise Some S's—are—some M's (I).
Conclusion ∴ Some S's—are not—any P's (O).

2. In Comprehension.

Major Premise Some M's—are—some S's (I).
Minor Premise Any I's—are not—any M's (E).
Conclusion ∴ Any P's—are not—some S's ($\frac{1}{2}$ E).¹

¹ The Toto-Partial Negative in *Ferio* is avoidable, if, adopting a hint already thrown out, we read the mood as *Celarent*, by interpreting the minor term as distributed: "All the things we call some S's." Its transference to comprehension then yields again I²EE.

If, throwing aside figure fourth, we do thoroughly convert all the propositions of all the fourteen named moods in the others, we double our list of admissible moods. The twenty-eight thus appearing are just so many of Mr Thomson's or of Sir William Hamilton's. It may be convenient, both for students of those systems, and for any who may wish to test minutely the suggestions here offered, that the twenty-eight be summarily identified with the corresponding moods of those authors. Mr Thomson (p. 248), has tabularized all Sir W. Hamilton's moods, translating the names into his own symbolic letters. A, E, I, O, retain their old significations: our A², Hamilton's toto-total affirmative, is Thomson's U; our I², the parti-total affirmative, is his Y; our $\frac{1}{2}$ E, the toto-partial negative, is η ; our $\frac{1}{2}$ O, the parti-partial negative, is ϵ . Our own symbols, here to be repeated, are easily interpretable into either of the other sets.

The formal outline of Hamilton's scheme is this. The first three figures only are admitted. The eight possible forms of predication being accepted, there are, in each figure, twelve valid affirmative moods. Each of these yields in each figure two negative moods: No. 1, by making the major premise negative; No. 2, by making the minor premise negative. There are thus, in each of the three figures, 36 moods: 12 Affirmative, and 24 Negative. Sir W. Hamilton's moods are, accordingly, 108 in all. Mr Thomson reduces the number to 63, by rejecting 45 moods, which introduce $\frac{1}{2}$ E or $\frac{1}{2}$ O, or both.

In identifying the moods, we must bear in mind certain consequences of the conversion. By converting the conclusions, we make transposition of premises necessary for all the three admitted figures. The conversion, also, throws the Second Figure into the Third, and the Third into the Second.

In the Fourth Figure, conversion of all propositions would only displace one anomaly to make room for another. Not recognised in the new scheme, it can be treated only by having all its predications thrown into the same whole, and the premises arranged for the first figure. If they are all expressed in extension, we gain, except for one mood, named syllogisms of the common scheme; and its moods, so treated, may then be transferred, if we will, to comprehension.

In the following summary, the Named Moods, and their converse equivalents, are referred to the numbers which the Affirmatives bear in Mr Thomson's table, from i. to xii., the Negatives under each being noted as 1 and 2.

Doctrine of inference.

19. FRESISON.....EIO — Unacknowledged.

2. Re-arranged Form; yielding Figure I. in Extension.

15. BRAMANTIP...AAA — No. iii. (=Barbara).
16. CAMENES.....EAE — From No. ix., Neg. 1: (=Celarent).
17. DIMARIS.....AII — No. v. (=Darii).
18. FESAPO.....EI²O — From No. viii., A²I²I²: Neg. 1.
19. FRESISON.....EIO — From No. xi., Neg. 1: (=Ferio).

When *Fesapo*, as thus thrown into the first figure, is transferred from extension to comprehension, it gives AB $\frac{1}{2}$ E, from No. viii., AA²A, Neg. 2. The readings of the other moods of the fourth figure in comprehension, are supplied by the named moods of the first figure.

DIVISION III.—THE FUNCTIONS OF THE SYLLOGISM AND OF THE SYLLOGISTIC FIGURES.

Abbreviations of thought, and sup-pression of steps in reasoning.

96. Thought is more rapid than speech, by an excess which hardly can be over-estimated. Of the characteristics common to all languages, as well as of those which are peculiar to each, an immense proportion are, as it has justly been said, nothing else than expedients devised for the purpose of abbreviation. The inequality of the race causes diversity in the kinds of motion. Thought may proceed by steps; language, in the endeavour to keep

up with it, must and does advance by leaps. When we throw our thinking into words, though it be only in self-communing, we continually pass, with a bound, over those steps which, for ourselves, are plainly and necessarily implied: when we aim at imparting our thoughts to others, we suppress similarly everything which it seems safe to leave in implication.

The desire of compression becomes especially active when concepts are the elements; for here we are forced on words, on common terms, as well in silent thought as in utterance. This is one of the causes why, although imagination may dart from object to object with the swiftness of the telegraphic flash, reasoning, burdened by its weight of words, must travel from truth to truth with comparative slowness. But we strive incessantly to expedite the journey.

Thus, as has already been observed, propositions, after having been distinctly thought, are made to yield complex terms, which supply their place: "This man is amiable," is substantially preserved in the form, "This amiable man." Such abbreviation gives, among other products, the means of substituting, for the cumbersome form of hypothetical reasoning, the simpler form of reasoning categorically. In the meantime, dealing with the latter species of thinking, we have to note the fact, that mediate inference brings the abbreviative tendency to light in another shape. In a large majority of actual instances, such inference assumes an appearance which disguises its real character. We have reached the utmost limits of direct abridgment: we strive towards the same end by having recourse to suppression. Not merely when we impart thought, but also very often when we think without communication, we evolve to ourselves, we extricate in explicit judgments and propositions, those steps only of our reasoning which the state of our knowledge causes to need explication.

We suppress one of the two premises of a syllogism: often we throw the whole of it into one complex assertion: "The X's are Y's, therefore they are Z's"; or, "The X's, being Y's, are Z's." A syllogism expressed thus incompletely is technically called an *enthymeme*.¹

The state of things may be best observed through the First Figure. This figure, when considered as to its matter, is a process in which a given principle or law, the compass of which is known, is applied to a given case, or cases. The major premise asserts that certain cases M are governed by the law P; the minor premise asserts that the given case S is one of those certain cases M; the conclusion asserts that the given case S is governed by the law P.

Now, in solitary thinking, it can happen but seldom,—in the transference of thought from mind to mind it will not happen very often,—that both of the antecedent truths shall demand to be explicitly brought up to the surface. In most instances, the premise which we wish to present clearly, to ourselves or to others, is the minor, asserting the identity of the given case S with one of the cases M. We follow this assertion immediately, by inferring that the case S is governed by the law P. The implied assertion of the major premise, that all the cases M are governed by the law P, may safely be left unexplicated if two conditions concur: first, that it shall be undeniable; secondly, that it shall necessarily be suggested by the two express assertions. The suppression of the minor premise may have place when our position is reversed. But that of the major is by far the more common: we leave the compass of the law unexpressed; we affirm only the inclusion of the given case in that compass.

¹ This is the scholastic meaning of the word: but, as Hamilton has shown, it had, in its Aristotelic acceptation, no reference to form. Aristotle's *enthymeme* was an inference in matter necessary; his *enthymeme* was an inference in matter probable. (See also Bachmann, p. 260.)

Doctrine of inference.

97. The necessity of the suppressed premise, as one of the steps in mediate inference, is demonstrable indirectly, through the supposition of its being either supplied wrongly or denied.

The logical necessity of explicating suppressed premises.

Let the terms be symbols of indeterminate meaning: "All Y's are X's; therefore all Y's are Z's." Evidently there is here an argument, on the validity of which a person unfamiliar with logical analysis might be puzzled to decide. Every one would perceive that some assertion is implied: many might supply the deficiency wrongly. "All Z's are X's" might suggest itself to some, and would vitiate the argument. The right premise wanted, the major, is, "All X's are Z's." Let that premise be denied, and any one would pronounce the reasoning inconclusive.

When the terms are determinately significant, our previous knowledge, and our practice in reasoning, concur to make it very unlikely that we shall catch up a wrong premise instead of the missing one. But we shall always discover the necessity for supplying something. "This theory is a novelty in science; therefore it is dangerous." The required major is the assertion, that "All scientific novelties are dangerous." Those who admit this major must admit the conclusion: those who deny it are entitled to assert that the conclusion is unproved. "All Mr M.'s opinions deserve great deference: therefore the opinion that we can infer from one premise deserves great deference." Palpably, there is here implied a minor premise, asserting that the opinion inferred of is an opinion of Mr M.'s. It being admitted, the reasoning is good: if it be denied, the reasoning goes for nothing.

To the argument thus raised, no sufficient answer has been given, by any of those who have maintained the inessentiality of the suppressed premise. They have not been able to show how we could dispense with the *major* premise. Its suppression indicates, only, that the compass of the law which founds the argument is supposed to be so evident, and so directly suggested, as to make the statement of it unnecessary.¹

Supposed suppression of the minor syllogistic premise.

98. With the suppression, much less usual, of the *minor* premise, the objectors have dealt less closely. But one argument referable to this premise brings out a distinction, which disposes of many very plausible instances urged as difficulties.

"A naturalist finds the remains of a horned quadruped, and pronounces that it was a ruminant animal. The reasoning here, if considered as class-reasoning, is perfectly expressed by a single premise with the conclusion. All

horned quadrupeds are ruminant; therefore this horned quadruped was ruminant. A logician may say, 'Yes; but you here comprise in the conclusion two facts or propositions; and when these are separated, you obtain a regular syllogism. All horned quadrupeds are ruminant; this quadruped had horns: therefore it was ruminant.' The introduction of a separate proposition, nevertheless, is obviously forced; it adds no strength to the inference, and represents no separate mental operation."¹

The introduction of it would, at all events, be in many cases quite needless. Not a few of the stereotyped logical examples are in the same predicament with this, of seeking to expand into a syllogism an inference which may be regarded as not really syllogistic,—as being, not mediate, but really immediate. It has appeared already that a syllogism in the first figure is a process of double subalternation. When we can safely infer from the subalternant directly to a subalternate, we always do so; but, if we cannot, we may still be able to infer, from the subalternant, through a proximate subalternate, to the still lower subalternate in which we are interested. In the former case, we have an Immediate inference; in the latter, we have an Inference Mediate or Syllogistic. In which of the two forms we shall either think or speak, is a question which we decide by considering the circumstances in which we are, or suppose ourselves to be. In the first form of the example quoted, the subalternate term, "this horned quadruped," expresses a complex idea, which is supposed to have been antecedently extricated from the proposition, "This animal is a horned quadruped." It is assumed, in short (as in an instance so simple it safely may be), that the fact of the animal being a horned quadruped is not worth explication into a proposition; and, on this assumption, our inference is immediate. But, if we were anxious to invite to that fact the attention either of ourselves or of others, we should require to explicate it: and the inference would become mediate. The minor premise would certainly, in this alternative, be expressed; and, further, if the compass of the law were doubtful (if, for example, we addressed ourselves to persons unfamiliar with zoology), the major premise would have to be expressed also.

In a word, arguments, where the minor premise seems to be suppressed, are really, in a majority of instances, as in this, cases of simple subalternation. There is no spell in the triplicity of the syllogism; and an inference not requiring expansion into the syllogistic shape, should never be violently stretched into it.

99. In every argument, then, which is actually thought to be a mediate inference, two premises are necessary as the Antecedent; although, not in communication only, but also in uncommunicated thought, one of the two may be unevolved when the argument first presents itself, and may remain unevolved unless a call arises for analysis. The accusation made against the syllogism, of representing, as embraced in mediate inference, more steps than those which it really contains, cannot be entertained.

The alternative charge, that the conclusion of a syllogism is virtually implied in its two premises together, is true; and the admission will be estimated very lightly, by those who have a just insight into the close limitations which shut in human reasoning on all sides.² Every original or primitive truth is individual, and is gained, not by reasoning, but by observation of our own thoughts or of the world around us.

¹ There is felt, it must be confessed, a difficulty, seemingly insurmountable, in seeing how Mr Mill's acute and instructive theory of the syllogism affects the major premise farther than by throwing it a step out of the way, while requiring also its being brought back, when required, for the thorough testing of the argument. "All inference is from particulars to particulars: general propositions are merely registers of such inferences already made, and short formulæ for making more. The major premise of a syllogism, consequently, is a formula of this description; and the conclusion is not an inference drawn from the formula, but an inference drawn according to the formula; the real logical antecedent or premises being the particular facts from which the general proposition was collected by induction. These facts, and the individual instances which supplied them, may have been forgotten; but a record remains, not indeed descriptive of the facts themselves, but showing how those cases may be distinguished, respecting which the facts, when known, were considered to warrant a given inference. According to the indications of this record we draw our conclusion, which is, to all intents and purposes, a conclusion from the forgotten facts. For this it is essential that we should read the record correctly; and the rules of the syllogism are a set of precautions to ensure our doing so." (*System of Logic*, book ii, chap. 3, sect. 4.) That the universal proposition, which is the major premise of the first figure, must, if it is a derivative truth (not otherwise), have been gained through antecedent induction, is a truth which cannot be too pressingly insisted on.

² Bailey, *Theory of Reasoning* (1851), page 81; a treatise whose objections to the received theory of the syllogism imply several very valuable suggestions.

³ "The general principle of the syllogism is formal identity; that is, identity between the antecedent and the consequent. One of the premises must contain the conclusion: the other must declare that the conclusion is there contained." (Galluppi, *Lezioni di Logica e Metafisica*, ed. 1854, i. 306.)

The function of the syllogism considered generally.

Doctrine of Inference. Even one such truth cannot be generalized, that is, it cannot be asserted to be a truth in more instances than one, unless through processes which are derivative thinking of one kind or another,—processes which must be inferences, either directly from one judgment to another, or indirectly from one judgment to another, through a third. The necessity of the truth revealed in a presentative cognition finds its normal expression in “this must.” It is not till we have reflectively thought out the possibilities of generalization, that the same truth is expressible as necessary through “all are.” Still more evidently is it impossible that, otherwise than through inference, such generalized truths can be brought to bear on cases, their application to which had not been directly observed.

Knowledge is digested through the two processes thus described: the ascent from this and that observed object to the generalized law of the class; the descent from the law to objects known only as included in the class. The processes are Induction and Deduction. Both are merely the disentanglement of relations given in complication, the distribution of known facts in masses as exponents of discovered laws. They yield systems in which our knowledge is symmetrically arranged, by induction according to the principle which rules its development into a whole, by deduction according to the principle which guides the determination of its several parts. That, by neither method of procedure, can any truth be discovered which is really different from the truths that lay at the root, is a fact which, while it springs necessarily from the limited character of human thought, does still leave to both methods their inestimable value. Between unreasoned knowledge, and knowledge systematically reasoned, there lies the world-wide distance between confusion and distinctness, between thick mist and brilliant sunshine, between the inert lifelessness of chaos and the rejoicing animation of the peopled earth.

On the operations which thus bring light out of darkness, logical laws merely keep a watch. They are guide-posts marking the track, topographical maps signalizing the points of the journey where thought is in danger of going astray. They are nothing more. Those laws of logical analysis, which require the throwing of the results of the operations into certain shapes, are only the alphabet through which we must read the inscriptions by the way-side, the key to the cypher which notes the facts discovered by the local survey.

This is the function discharged by all laws of Inference, from those of the simplest to those of the most complex kinds. It is emphatically the function of the laws ruling the Categorical Syllogism, a process which is the central point of all derivative thinking, rising above and passing beyond immediate inference on the one side, and standing on the other as the basis of all those more complex reasonings which take the more difficult syllogistic forms.

any exception, because of an occasion presenting some Doctrine of fact or facts, whose subjection or non-subjection to a inference. known law is not immediately obvious. We know the law; and we know its compass: there is thus matter for a major premise: all facts of a certain kind are either covered by the law, or are beyond the sphere of its operation. We know, likewise, that the fact about which we wish to reason is one of the facts which thus stand within or without the domain of the law; and this knowledge supplies a minor premise. Our data having thus been placed in exact relations to each other, there follows, inevitably, the judgment, that the narrower fact is subject or not subject to the law. The inference has been set in a form making it both clear and readily testable: and this formal setting forth of it has been made possible, by our having already arranged the three terms in a scale of ordination.

Perfect as a form of inference, the first figure is, just because of the regular sequence of gradation which it assumes, less likely to occur in ordinary thinking, whether with or without expression of both premises, than either of the other figures. In many actual cases, if not in most, the consequent is attainable through an immediate subalternation. Its uses are scientific oftener than popular. It is invaluable as exhibiting the principle on which mediate inference must ultimately rest; and as thus being, directly or indirectly, the most decisive instrument for testing the validity of arguments that are either disputed or not distinctly wrought out.¹

101. The Second Figure expresses a knowledge deficient by one step only, but that a step so important as seriously to cripple the inference. The special functions of the second figure.

The thinking which it expresses is indistinct, in the wider of the two judgments which supply the premises. In the *major* premise, as it has been shown, we turn aside from the route of deduction. We do not directly think the compass of the law, either positively or negatively: we do not explicitly place our intermediate cases either within the law or out of it. We start from the thought of the law itself and predicate of it that it lies out of all the intermediate cases. Doubtless, this assertion implies that the cases are out of the operation of the law; but it does not clearly express the thought of this second assertion. The difference of form or expression is symptomatic of a real difference in thinking: the source of the difference lies in our not having systematically ordinated the thoughts denoted by the three terms; and we suffer for the shortcoming, by being tied down to a negative major premise. The inclusion of our given narrowest case among the intermediate cases, yields a minor premise; but the exclusion of that case from the law is the only consequent attainable.

If, however, a negative conclusion only is aimed at, this figure is equally available with the first; and, when the

The special functions of the first figure.

100. The specific uses of the Syllogism vary with the several figures. Enough has been seen already to show that none of the first three, which only deserve scientific recognition, can be without applicability. We gain a bird's-eye prospect of the relation between the syllogistic figures, in the course of that coasting voyage which we pursue under the pilotage of the scholastic rules; but the system of stratification, which contains the wealth of the gold-region, lies concealed, until, having mastered the doctrine of the Wholes of Predication, we travel into the heart of the country, to survey it as mining engineers.

The First Figure is the characteristic expression of knowledge already systematized, of *deduction* from principles accepted as ruling within a certain sphere.

When, for the explication of such knowledge, mediate inference is requisite, it is almost always, if not without

¹ To the first figure is applicable, one might even say exclusively, Mr Mill's description of the function of the syllogism (note to section 97), as being a code of rules for the interpretation of that abbreviated record of knowledge, which is embodied in universal propositions.

The protest of Ramus, against the speculative tendencies of the Aristotelians, guided him and his followers to some instructive views as to the functions of the several syllogistic figures. They declared the third figure to be (oftenest in an enthymematic form), the first and most natural mode of dialectic or discursive thinking. Dividing, as usual, by dichotomy, they placed over against it a class containing the other two figures. But, in that class, the second figure, as having the simpler formal relation between the middle and the extremes, stood before the first. “The figure which Aristotle calls the first, is in the order of nature the last.” This remark is Milton's, whose logical treatise illustrates very ingeniously the Ramist system of dialectics. (Compare Ramus, *Institutiones Dialecticæ*, lib. ii., capp. 10, 11, 12; with Milton, *Artis Logicæ Plenior Institutio*, in his Prose Works by Birch, ii. 545-551.)

Doctrine of major is the suppressed premise, it will be filled up for either figure, according to the greater or less distinctness with which the thinker has classified his knowledge of the matter handled. Where, indeed, the aim is the detection of differences, while positive attributes, as clearly known, are not attended to, our familiar deductions are likely to fall into the second figure rather than into the first. For the law of identity and non-identity, which glimmers out from afar, above all our thinking, as the twin star by which it must always steer, has its most obvious bearing when the middle term has the same function in both premises.

The consideration last hinted at is applicable with peculiar force to the remaining figure, which, as having distinctive uses infinitely wider than the second, must receive much closer attention.

The special functions of the third figure. 102. The practical uses of the Third Figure are both more various, and more firmly marked, than those served by either of the others.

It is distinctively the *exceptive* figure. A law being asserted as universal, the exhibition of any instance (our middle term) in which it is violated, entitles us to deny the universality in our conclusion. Both positively and negatively, also, it is the form by far most natural for *exemplification*: the middle term is set forth as being, in a given class of objects, an instance in which a law is either obeyed or not obeyed; and hence we infer that there are instances in which the law either holds or does not. Further, both exception and example are sufficient, though there be but one instance of the sort. Hence our middle term is often a singular. This figure lends itself easily to the reception of such a middle, while no other will: and even uninstructed thought, guided by a twinkling suspicion of the ultimate laws of thinking, throws such reasonings into a shape in which the third figure is involved. In all applications such as those just described, the argument proceeds safely, and needs little or nothing either of warning or of guidance.

But the fact stands differently in regard to the most important of all the uses to which the figure may be applied; a use, indeed, towards which the others are only the first steps. The third is distinctively the *Inductive Figure*: and its character, as applicable to this purpose, must be looked at with all the closeness which our opportunities permit.

When we reason in the third figure, we start, as in the second, from a knowledge which is, at one point, incompletely systematized. If it now the cloud overhangs the opposite quarter of our horizon.

We possess the law; and we know its compass, either positively or negatively. The major premise asserts, of its two terms, the relation which they would be found to bear if our terms were thought in their just ordination: our intermediate class of cases is governed by the law, or disobeys it. It is in the *minor* premise that the clue of the deductive maze has been lost. We cannot there assert, that the case or cases as to which we desire to infer, or any of them, are included in the intermediate class; we can assert only that the intermediate class, or some part of it, is included among the cases about which we are directly concerned.

Our position is seductively promising. The intermediate class, denoted by our middle term, is pronounced to be, wholly or partly, either identical with both of the classes denoted by our other terms, or identical with the one of the two, and non-identical with the other. But, in the step signified by our minor premise, we have turned aside from the deductive sequence; and the penalty must be paid. Our conclusion is valid only as to a part of the class of cases about which we aimed at inference. We are not secured against disappointment unless, being forewarned of the limitation, we have in the beginning narrowed our sphere to a part of that class. If, not having thus pro-

tected ourselves, we draw an universal conclusion, we have stumbled into an illicit process of the minor term. Doctrine of inference.

The process which has thus been described, from the objective side, is that which bears the name of Induction. Our universal affirmative propositions, those which express the whole compass of laws, and which become available as the major and confining premises for processes of deduction, have, if they are truths derived from others, been antecedently gained, by us or for us, through induction. Further, those inductions, as actually performed, proceed from data no wider than those explained here, and in the formal scrutiny of the third figure. Yet induction takes place, naturally and usually, in forms which, when completely and exactly set forth, fall into the third figure: while, if it be, in certain circumstances, referable directly to the first, its mood is inevitably one of the two which authorize only particular conclusions. Consequently, an incalculably large proportion of the universal affirmatives, from which, in deduction, we travel downwards, have been reached by a method whose prohibitory laws have been disobeyed. Our ordinary inductions, having conclusions universal instead of particular, are logically inconclusive. Some logicians have rightly called them Imperfect Inductions. There is, indeed, a possible process, describable as a Perfect Induction. As deduction is valid only from a whole to any of its parts, from a genus to any of its species; so induction is valid or perfect only from all the parts to the whole, from all the species to the genus. If, being able to assume only that a law governs some of the species, we hence infer that it governs the genus, our induction is imperfect, and our inference fallacious. If, being able to assume that a law governs all the species, we were hence to infer that it governs the genus, our induction would be perfect, and our inference valid.¹ But the data for such a process are never extant when they are most wanted: our common procedure does never, in the most favourable circumstances, supply them completely. All these truths must be resolutely faced.

103. The Third Figure, while it may, doubtless, like the second, be adopted needlessly, is yet the only form which inference can naturally assume when we are bent, not on determining or specifying universal truths already known, but on enlarging our knowledge, by widening our sphere of generalization. In deduction we argue from the subalternant to the subalternate, from a given class to something contained in it. "Because all are, some are:" the inference is good. In the imperfect induction we argue from the subalternate to the subalternant, from something given as contained in a class to the class itself. Our inference is bad, as passing beyond the sphere of our immediate premises: whether we conclude, peremptorily, that, because some are, all are; or only that, because some known objects of the class are, therefore some unexamined objects of it must be also.

It is because of the logical weakness, which thus per-

¹ The Perfect Induction is dealt with by Joannes Major, in one of the passages already quoted from (note 2 to section 39). Derodon exemplifies it by the following syllogism, which is really in AA²A of the third figure: "Ignis, aer, aqua, et terra, sunt corpora; sed ignis, aer, aqua, et terra, sunt omne elementum: ergo omne elementum est corpus." (*Logica Restituta*, 1659, p. 602.)

The following are the two formulæ of perfect induction proposed by Sir William Hamilton in 1833:—

X, Y, Z, are A :	A contains X, Y, Z.
X, Y, Z, are (whole) B :	or, X, Y, Z, constitute B.
∴ B is A.	∴ A contains B.

See his *Discussions*, p. 161; and compare Baynes, *New Analytic*, pp. 71, &c. Consult also Mansel, *Prolegomena Logica*, pp. 207–211; Trendelenburg, *Logische Untersuchungen*, ii., pp. 261–3; Drobnich, *Neue Darstellung*, §§ 140–146. On the objective side, see Whately, *Elements of Logic*, book iv., chap. i., § 1.

Doctrine of inference. vades all ordinary inductions, that arguments from experience, analogy, or example, in questions relating to human character and conduct, are so apt to be delusive, and require to be scrutinized with so much jealousy. It is because of the same weakness, that arguments of the same type, when used as instruments in the construction of scientific systems, are felt to need fencing round by an array of checks and counter-checks. Such an array constitutes the code of laws which is usually called the Philosophy of Induction; a code diversely promulgated by diverse lawgivers, and admittedly susceptible, in all its editions, both of improvement and of enlargement.

Perhaps the simplest view which can be taken, of the design aimed at in the inductive laws, is this. The imperfect induction leads to a conclusion, which, if stated as universal, involves a logical error: it is required to reduce that error to as narrow a limit as possible; and it is an end not only desirable, but in many cases attainable, that the error shall be narrowed to a minimum which is practically inappreciable. If, the conclusion being stated as a universal ("all are" or "all are not"), the attempt is yet made to give warning of its amount, that amount might be indicated, in the predicate, through the degrees of a modal scale, loosely indicable thus: "Perhaps, probably, very probably, probably in a very high degree, probably in the highest degree thinkable below demonstrative certainty." If, on the other hand, it were attempted to intimate the amount of the error through the subject of the conclusion, the notice might be given through a corresponding scale of quantitative symbols: as, "A few, many, very many, almost all, all that there is any reason for believing to exist." The raising of the inductive conclusion to the highest of these degrees, whether of qualitative probability, or of quantitative inclusion, may be said to be the end aimed at through the inductive laws; such laws, for instance, as those which Mr Mill proposes under his four "Methods of Experimental Inquiry," the methods of Agreement, Difference, Residues, and Concomitant Variations.

How are any such laws effectual? And how is truth attainable through a process which, so far as we have yet examined it, appears to leave open the chance of error?

Laws are applicable to the case, truth is attainable through the process, by reason of this fact. The explicative process is and must be, at one stage or another, amplified by an assumption not implied in the data. Further, that which is assumed must be a necessary and universal truth; it must be a truth which thus lies above the universe of experience, but which becomes known to us only through our experience of individual facts, while it is expressible only by reference to the relations under which those facts became objects of cognition. When regarded in its most concrete and complex aspect, the principle is spoken of by such phrases as "The uniformity of nature." Specified from a higher point of view, it yields the assertion that "Every fact or phenomenon is governed by a law or laws:" and, when we look down on it from a station yet more elevated, it resolves itself into the doctrine, that "Like causes produce like effects."

This principle rules human activity quite as sternly as it rules the passivity of corporeal matter. But the laws, the causes, are not the same. Will, indeed, predominates over both regions; that all-directing and sustaining Will, in the thought of which is found the last solution of the problem raised, when we trace law and cause upwards into pre-formed purpose or design. That universal energy, however, being reverently taken for granted, we see that mind exercises volition of its own, that it acts, or exercises its powers, in virtue of will; while body merely obeys the universal laws of its nature, whether left to itself, or influenced, in conformity with these, by the will of man. Hence it is that the generalization of reasonings about mind is, and must always

continue to be, so much more hesitating and precarious than similar generalization about things corporeal. Given a cause, that is, given all the elements of a cause; it must always be possible to prognosticate the effect. But we may know all the causes which immediately influence body: we never do or can know all the causes which immediately influence mind; and this impotence imposes a limit on the certainty, both of a generalized law, and of its application to an individual fact.

Doctrine of inference.

104. Though the fourth figure is certainly useless, it is clear that both the second and the third represent forms of reasoning, which are not only actual but frequent; while the third, likewise, is the natural form of our common generalizations. The uses of syllogistic reduction.

Reduction of syllogisms, then, to the first figure, cannot well be maintained to be necessary on a ground which has been hinted at by one great philosopher, and regularly developed by another.¹ The imperfect moods, it has been said, are really Mixed Inferences: each of them implies one or more immediate inferences by conversion: and it is from these implied premises, not from the expressed ones, that the conclusion is mediately inferred. The substituting of the implied propositions for the expressed ones, is the reduction of the syllogism.

The process of thought supposed by this theory, is not that which actually takes place. When an argument is expressible as a syllogism in a mood of any indirect figure, we have really thought in that figure, not in the first.

But reduction, though it does not show what the given inference really was, does show what it might have been: and herein is its usefulness to be found. We had fallen into the given figure, because, whether through imperfect knowledge or through want of reflection, we had not distinctly thought the three concepts of our reasoning, in the relations which they must bear to each other as members in a classified series. Reduction brings those relations to light, exhibiting the three terms as being, successively, contained, containing and contained, and containing. Now, likewise, there becomes directly applicable to our argument the law of subalternation, the highest concrete principle by which reasoning through common terms admits of being tested.

Accordingly, the transformation of Indirect syllogisms into Direct, should be considered as being only a valuable means of analysing, to the furthest possible point, the elements of a given argument. Every indirect syllogism may, with immediate reference to its conclusion, be held to be a genuine form of thought, resting on a foundation which, though neither the widest nor the deepest of those that underlie it, is yet perfectly strong enough for its support.

Now, therefore, when our study of the simple categorical syllogism is completed, not only may we ask, whether the attempt has been made to propound any laws governing, indifferently, syllogisms of every form; but we may also collect some of those many codes of maxims, in which it has been attempted to draw to a point the functions and formal rules of the several figures.

105. The question as to universal laws of the syllogism reminds us of the two Syllogistic Canons. These, the oldest laws of the sort, were sufficiently examined in a previous section. Specimens of proposed syllogistic canons.

¹ The hint is Aristotle's: *Analytica Priora*, lib. I., cap. 1; *sub finem*. It is developed by Kant, in one of his minor treatises: *Die falsche Spitzfindigkeit der Figuren*. By him, and those who have followed him most closely in the application of his doctrines to logic, such as Kiesewetter, the indirect syllogisms are called Mixed or Hybrid. Schulze calls them syllogisms Extraordinary or Transposed: *Grundsätze der allgemeinen Logik*, ed. 1831, p. 118. Kant's view had been virtually anticipated by the paradoxically acute Derodon: *Logica Restituta*, p. 647.

ceding division of the present chapter. But emphatic commemoration is here deserved by that resolution of the canons into the laws of identity and difference, which was then quoted from Smiglecius.¹ Somewhat later than his time, the same reference was carried yet farther. "For all syllogisms," says Derodon, "whether affirmative or negative, this one principle is sufficient; that things which are the same with a third thing are the same with each other. The principle requires no limitation whatever."²

In the logical systems of the modern Germans, the ultimate dependence of the syllogistic rules on the laws of identity and difference, is generally insisted on, and more or less satisfactorily traced. But we do not encounter, among them, more than a solitary attempt to deduce, for the syllogism, one universal canon, exhibiting the application of the two axioms to the concept. These logicians, however, are very lavish in generalizations of the rules and characteristics of the several figures; and some of the doctrines they have proposed may usefully be cited.

In the First Figure, says Lambert, the middle term is a ground or reason; in the Second it is a difference; in the Third it is an example; in the Fourth it is a ground of reciprocity. "I. The law of the First Figure is the *Dictum de omni et nullo*: What is predicated of all A's, may be predicated of every A. II. The law of the Second Figure is the *Dictum de diverso*: Things which are different, cannot be predicated of each other. III. The law of the Third Figure is the *Dictum de exemplo*: When we find things A which are B's, there are A's which are B's. IV. The law of the Fourth Figure is the *Dictum de reciproco*. (1.) If no M is B, no B is this or that M. (2.) If C is or is not this or that B, there are B's which are or are not C's."

By the same close analyst, the functions of the four figures are otherwise distinguished in this way:—"(1.) The First Figure appropriates to the thing what we know of its attribute. It infers from the genus to the species. (2.) The Second Figure leads to the difference of things, and removes confusion of concepts. (3.) The Third Figure gives examples and exceptions for propositions which appear universal. (4.) The Fourth Figure finds species for the genus, in *Bramantip* and *Dimaris* it shows that the species does not exhaust the genus, in *Fesapo* and *Fresiso*; and it denies the species of that, whereof the genus is denied, in *Camenes*."³ We shall not again find mention of the fourth figure.

Consideration is called for by a generalization wider than this. Herbart distributes the three figures into two classes. The First and Second are called Syllogisms of Subsumption, in respect that in each of them the minor term is subsumed or subordinated under the middle: the Third Figure is said to have Syllogisms of Substitution, their character consisting, it is alleged, in the substitution of one term for another.

One of the most acute thinkers of Herbart's philosophical school, while dissenting in part from the distribution, has expressed the laws of the three figures with pregnant brevity. "The First Figure," says Drobisch, "may be said to reach its conclusion through subsumption, the Second

through opposition, the Third through substitution."⁴ He assigns both a universal law of the syllogism and special laws for the three figures, in the following propositions. In the first of these, M denotes the middle term, A and B the terms of the conclusion; the functions of all these terms, as subject or predicate, being left unfixed.

"A conclusion will always be yielded, when it can be shown, that the whole or a part of the sphere of A, through its relation to the sphere of M, and the relation of M to the sphere of B, is either contained in the sphere of B, or excluded from it.—I. For obtaining syllogisms of the first figure in conformity with this universal principle, the application of the two following laws is sufficient: (1.) In that, wherein the whole is contained, there is contained also its part; (2.) From that, wherefrom the whole is excluded, there is excluded also its part.—II. Syllogisms in the second figure are yielded through application of these two laws: (1.) The part of a whole is excluded from that which is excluded from the whole; (2.) That which is excluded from the whole is also excluded from its part.—III. Syllogisms in the third figure are yielded through application of this law: Identical determinations of a concept may be substituted for each other."

Twisten gives thus the laws of the three figures. "I. In the First Figure, we infer from the genus to that which is under it, by the so-called *Dictum de omni et nullo*. It may be regarded as a widened subalternation. II. In the Second Figure, from the opposite relation of two concepts to a third, we infer to their own opposition. It may be regarded as a widened opposition. III. We may consider the Third Figure as an application of the analytic [explicative] law, that there is given, with a concept, the agreement of its marks. The procedure in it is according to this principle: Concepts which may be predicated of the same subject, may be predicated of each other, though only with limited quantity or modality; concepts, on the contrary, of which the one, but not the other, may be predicated of a certain subject, may be denied of each other, under the same limitation as before."

106. The only other shape of the laws calling for citation, is that in which they have most recently appeared, and in which they are designed to cover, not only the current syllogistic scheme, but likewise all the new moods proposed by their author.

The form in which Sir William Hamilton expresses his one universal canon of the syllogism is this. "What worse relation of subject and predicate subsists between either of two terms and a common third term, with which both are related, and one at least positively so: that relation subsists between those two terms themselves." The same law is given by Mr Thomson, in a form bringing it nearer to being a combination of the two received canons. "The agreement or disagreement of one conception with another, is ascertained by a third conception; inasmuch as this, wholly or by the same part, agrees with both, or with only one, of the conceptions compared."

To the work last quoted from, the author of the universal canon furnished also the following specified applications of it to the several figures:—

¹ Section 82; and its second note.

² *Logica Restituta*, pp. 642, 644. Negative syllogisms he brings under the law of affirmation by contraposition. The absolute identity of the objects denoted by the extremes he maintains chiefly on metaphysical grounds, similar to those urged by Smiglecius: but one section in his argument shows him to have apprehended (not very distinctly) the doctrine, that the quantitative signs are integral parts of the terms.

³ Lambert, *Neues Organon*, 1764, vol. i., pp. 136–143; "Disaioic logie," section iv. Mr Thomson has traced the substance of Lambert's laws, except that for the fourth figure, to Keckermann; and perhaps they are still older. (Thomson, *Laws of Thought*, p. 228; Keckermann, *Systema Logicae [Plenius]*, ed. 1614, lib. iii., capp. 5, 6, 8, 9, pp. 748, 756, 757.)

⁴ Herbart, *Einleitung in die Philosophie*, ed. 1850, p. 111. Drobisch, *Neue Darstellung der Logik*, ed. 1851, sections 81–88. The distinction between Darapti and Felapton on the one side, Datisi and Feriso on the other, was not overlooked by Herbart. But, followed by Drobisch, he uses it by founding on the double distribution of the middle in the first two of those moods, and taking them as the norms of his "substitutive inferences." Surely, however, the character of the third figure is very loosely apprehended when it is said to rest on substitution.

⁵ Twisten, *Die Logik, insbesondere die Analytik*, 1825, §§ 105–109.

Doctrines of inference. *Figure I.*—In as far as two notions are related, either both positively, or the one positively and the other negatively, to a third notion, to which the one is subject and the other predicate; they are related, positively or negatively, to each other as subject and predicate.

Figure II.—In as far as two notions, both subjects, are, either each positively, or the one positively and the other negatively, related to a common predicate-notion; in so far as those notions, positively or negatively, subject and predicate of each other.

Figure III.—In as far as two notions, both predicates, are, either each positively, or the one positively and the other negatively, related to a common subject-notion; in so far as those notions, positively or negatively, subject and predicate of each other.¹

The propositions which have been cited, in this section and the last, may suggest more reflections than one. Each of the codes of laws struggles towards one principle, and is clearly intelligible when that principle is understood and remembered: we are led, everywhere, to look back on the law of non-contradiction, with a beckoning, more or less emphatic, towards the character of concepts as the objects on which the law is brought to bear. Each of the codes, again, is, for those who have mastered the received rules of the syllogism, easily interpretable, as being nothing else than a generalization of them. But, on the other hand, the bolder the generalization is, the more difficult does it become to descend again to the received rules; if, indeed, we have not, at one or two points, been guided completely beyond sight of them.²

CHAPTER IV.

COMPLEX MODES OF INFERENCE.

DIVISION I.—INFERENCE BY COMBINATION OF CATEGORICAL WITH NON-CATEGORICAL PREMISES.

The character of conjunctive propositions.

107. We assert and reason categorically, through assumption of the relations between terms. This is the form which judgment naturally and spontaneously takes when its data are positively assumed; and no long series of judgments deviates steadily from it. That we may be able to adopt it, we continually throw into the shape of complex ideas and terms the judgments which we desire to develop further. To this form, likewise, thought must be reduced, before the primary logical laws can be made to bear directly on it.

But there are propositional forms which are not categorical. Such may be said to be all those with which, under

the name of "Exponible" or "Compound" prepositions, we have already made up a passing acquaintance.¹ These are formally distinguished from categoricals by their complexity: each of them is constituted by two or more propositions that are categorical. Each of them, again, may be analyzed into its constitutive categoricals. Further, most of the kinds of exposables do not become rightly available as data for inference, till that analysis has been performed. The inferences then issuing from such propositions are traceable immediately to the relations of the terms, and consequently are ruled directly by the laws of categoricals.

This limitation of use, however, does not affect all exposables. The exception which has place is indicated by a difference in form. While, in most kinds, certain of the constitutive propositions are only implied, there are two of the kinds in which all the constitutive propositions are explicitly set forth. Propositions of those two kinds may be inferred from, without being subjected to an analysis deep enough to lay bare the implied relations of the terms. In inferring from them, we may content ourselves with assuming a relation, explicated in our complex proposition, between the propositions which constitute it. The peculiar character of the relation so assumed, impresses a peculiar form on the inference for which it becomes a datum.

The two kinds of complex propositions, which are susceptible of being thus dealt with, may have their common character indicated if they are called *Conjunctives*.

A *Conjunctive Proposition* neither affirms nor denies any of the constitutive propositions: it merely asserts a relation between them. It is either an *Hypothetical* (or *Conditional*) proposition, or a *Disjunctive*.²

An *Hypothetical proposition* is constituted by two categoricals; and it asserts that, on the hypothesis or condition that one of the constitutive propositions is true, the other is true also. "If X is Y. (then) Y is Z:" or, "If X is Y,

¹ Note II. to Part III., Chapter I.: *Interpretation of Propositions*.

² The name *Conjunctive*, for the genus, is that of the Port-Royal Logic, as well as of earlier works. There is an awkwardness, obvious and undeniable, in adopting this as a generic name, while the name *disjunctive* is applied to one of the two species. But the fault seems to be less than that of the terminology adopted by Whately, and others, from Aldrich, Sanderson, and most of the older English logicians. These give to the genus the name "hypothetical;" and they designate the two species as "conditional" and "disjunctive." But the words "hypothetical" and "conditional" are palpably synonyms: nor is the name "hypothetical" very apt for disjunctives.

In their treatment of the complex modes of inference, the German logicians, almost to a man, are elaborately and most ingeniously minute; but, alike in nomenclature, in method, and in resulting theory, they are as discordant as the extreme difficulty of the problems would make one expect to find them. Most of them cling, more or less closely, to the remarkably subtle analysis of Lambert. From him, likewise, one or two English writers have taken some of the mnemonic names ("Saccapa, Caspida," &c.), by which, emulating the "Barbara" verses, he sought to symbolize the rules of those complexly-complex inferences, a few of which are touched on in the third division of the present chapter. It is but a very small part of those speculations that can be put to use in the summary here attempted.

Fries's distribution of judgments and propositions (*System*, p. 102), is worth notice for its bearing on complex inferences. Judgments fall, in respect of relation, into three classes. The relation of subject and predicate gives the *Categorical Judgment*; the relation of reason and consequent gives the *Hypothetical*; the relation of co-ordinates to the containing whole gives the *Divisive*. The *divisives*, again, are of two species: the *Conjunctive*, which is the "copulative" of many old logicians; the *Disjunctive*, which is the proposition commonly bearing that name. Copulatives, however, as was already observed, are really categoricals (Note II. to Part III., chap. I.); and, besides, they give but imperfect expression to that divisive relation, which is adequately set forth by disjunctives (compare section 56). The same remarks are applicable to the propositions which Drobisch calls "*Divisive*," as "*B is partly X, partly Y, partly Z.*"

¹ Baynes, *New Analytic*, p. 53. Thomson, *Outline of the Laws of Thought*, pp. 214-230. We have it not now to learn that particularity is a "worse" relation than universality, negation than affirmation. For the full development of Sir W. Hamilton's scheme, however, it has to be remembered, that in extension the subject is "worse" than the predicate, being thought as quantitatively a part of it; that in comprehension, for the same reason, the predicate is "worse" than the subject.

² The following works may be referred to, for other comparisons of the figures:—Melanchthon, *De Dialectica*, lib. iii.; *La Logique* (de Port-Royal), *partie iii.*, chaps. 5, 6, 7; Wolf, *Philosophia Rationalis*, 1728, pp. 311, 317, 320; Wyttenbach, *Procepta Philosophiæ Logicæ*, part iii., chap. 6, § 13; Maass, *Grundriss der Logik*, ed. 1806, p. 222—(the only one of the recent German logicians, so far as we know, that has attempted to generalize the rules of the fourth figure); Hoffbauer, *Anfangsgründe der Logik*, ed. 1810, pp. 164, &c.; Kiesewetter, *Grundriss einer allgemeinen Logik*, ed. 1824, vol. i., pp. (109), 403, 405, &c.; Fries, *System der Logik*, ed. 1837, p. 165; Kidd, *Primary Principles of Reasoning*, 1856, chap. v., sect. 4. For Mr Mill's reading of the law of the first figure, see his *System of Logic*, book ii., chap. 2., §§ 3, 4; and Mr Kidd's observations on the passage in chap. iii., § 1.

Doctrine of inference. (then) Y is not Z." The conditioning proposition is called the Antecedent, the proposition conditioned is the Consequent. The two propositions, accordingly, have functions corresponding, severally, to those discharged by the two terms of a categorical. A function parallel to that of the copula belongs to the "Consequence;" that is, the words "if" and "then," which express the relation between the constitutive propositions. Through these words (or more commonly, in our language, through the former alone), there is denoted the affirmation of the consequent, on condition of the affirmation of the antecedent.

A Disjunctive proposition is constituted by two or more categoricals: it asserts that one or another of these must be true, and the others false. "Either B is X, or B is Y, or B is Z;" or, "Either B is X, or C is X, or D is X." In almost every actual case, one of the terms (simple or complex) is, as in these examples, common to all the constitutive propositions; and, when the fact is so, the disjunctive is conveniently abridged into a form which would make it useable as a categorical having one term alternatively complex. "B is either X, or Y, or Z: Either B, or C, or D, is X." The place of the categorical copula is taken by the "Alternative" words "either" and "or." The import of these is double: they denote the affirmation of one or another of the constitutive propositions, and the denial of all the others. The constitutive propositions, again, represent the categorical terms; but none of them is tied down, as in hypotheticals, to the function of antecedent or consequent. For the character of the disjunctive relation involves an inconsistency, absolutely reciprocal, between any one of them singly, and each and all of the others.¹

Conjunctive propositions as antecedents of inference. 108. When conjunctive propositions are considered as premises or antecedents of inference, three points come to light.

First: The only inferences affected by the conjunctive character are mediate. The conjunctive proposition is one premise: a second proposition must be supplied as the other.

Secondly: A conjunctive proposition of either kind may, with another premise of the same kind, yield a conclusion also of the same kind. But such syllogisms, purely hypothetical or disjunctive, neither evolve, nor depend on, the assumed relations of the constitutive propositions: they are genuine categorical syllogisms, hidden under a disguise, which is thrown over them by the uncertainty of the thinker as to the legitimacy of the assumptions they postulate. The pure hypothetical inference springs from doubt as to the truth of the premises: the pure disjunctive inference springs from doubt as to the extension or comprehension of the terms.

The only syllogisms which do depend on and evolve the relations of the constitutive propositions, are those mixed ones in which the conclusion is categorical. The major premise is, for both kinds, the given conjunctive proposition. But, for both kinds, the minor premise must be categorical. In other words, the conditional or disjunctive relation is evolved, by being brought to bear on an unconditional and positive assertion of fact. In mixed hypothetical syllogisms, the minor premise is categorical, both formally and in substance. In mixed disjunctive syllogisms,

¹ Propositions disjunctive by negation are such as the following: "B is neither X, nor Y, nor Z: Neither B, nor C, nor D, is X." Evidently, however, these fall short, by more features than one, of the character assigned in the text to the disjunctive proper. Indeed, they may rightly be treated as affirmative categoricals, having one term negatively complex: "B—is—something which is neither X, nor Y, nor Z: That which is neither B, nor C, nor D—is—X." The introduction of such a proposition as a premise, when the other premise is categorical, would leave the syllogism directly amenable to the categorical laws.

the minor premise has often the disjunctive form; but it is always in substance categorical, an unqualified assertion of identity or difference between its subject and its predicate.

Thirdly: There appears a point, which, for the theory of these inferences, is the most important of all. The validity of categorical inference, from premises one of which is conjunctive, rests on this postulate: that the conjunctive premise shall be accepted as an affirmation of the result of certain antecedent processes. These processes have, for the two kinds, different characters, and rest on different principles.

(1.) An hypothetical proposition affirms the validity of an antecedent inference. It asserts that, the antecedent being admitted, the consequent must be inferred from it. The necessity of the inference may appear on the face of the hypothetical proposition; but much more frequently it does not. In either case, the proposition merely asserts that the inference is valid, while it presupposes the process by which the validity is established. It thus depends on one or more of the laws of inference, and is traceable through them to the axioms of identity and difference.¹

(2.) A disjunctive proposition affirms the completeness and accuracy of an antecedent process, which either is a logical division, or is ruled by the same principles as it. It asserts that the constitutive propositions set forth all the dividing members of the whole, and that these members exclude each other. It thus depends on the axiom of excluded middle.

This analysis of disjunctives covers all the actual cases. First: None of the constitutive propositions may have any of their terms identical: "Either B is X, or C is Y, or D is Z." Such a proposition is easily referable to a division having a very wide divisum: "All possible cases are cases, either of B being X, or of C being Y, or of D being Z." Secondly: Each of the constitutive propositions repeating one term, the disjunctive proposition may have singular terms only, and will thus assert, alternatively, individual identities only. In this unusual case, the assertion depends, obviously as well as directly, on the law of excluded middle. Thirdly: When its terms are common, one of them occurring in each of the constitutive propositions, the same dependence holds through the law of the concept. In such cases, a disjunctive proposition, in its abridged form, really asserts, of one of its terms (usually, but not necessarily, the subject), that its extension is constituted by the terms constituting the predicate. The predicate is an enumeration of co-ordinate terms, which are parts, and all the parts, of the extension of the subject. The proposition (if held to be a categorical, as it may be), is an A¹; and it affirms, or implies, a logical division carried down to one step only. It is so expressed as to signify, both the mutual exclusion of the parts, and the equivalence of their sum to the whole. Thus, the assertion that "All the B's are either X's, or Y's, or Z's," is interpretable as, or out of, this assertion; that the class B is constituted in extension by the three sub-classes X, Y, and Z. Categorical inference from such a premise is not possible, unless the members of the division are both mutually exclusive, and in their combination exhaustive.

109. From the description of the hypothetical proposition, there come at once the two laws of the Categorical and Hypothetical Syllogism, which is oftenest described simply as Hypothetical. Each governs one of its two moods,—the

The structure and rules of the hypothetical syllogism.

¹ Kant, and many other foreign logicians, place the hypothetical proposition by itself, alleging that it requires, for its justification, the doctrine of the "sufficient reason." But it was maintained, in a preceding note (section 15), that this doctrine, if understood as the assertion of a law purely formal, is resolvable into the axioms of identity and difference.

Doctrine of inference.

Constructive or Positive mood, and the Destructive or Amotive.¹

(1.) The Mood of Position rests directly on the principle of inference: if the antecedent is admitted, the consequent may be inferred. The minor premise, therefore, is an affirmation of the antecedent, the conclusion an affirmation of the consequent. "If X is Y, Y is Z; but X is Y: therefore Y is Z." "If every X is Y, no X is Z; but every X is Y: therefore no X is Z."

(2.) The Mood of Amotion rests on an immediate corollary of the principle, the same which is used for indirect demonstration. The inference expressed in the major premise being assumed to be valid, its consequent cannot be false, unless because its antecedent is so: if the consequent is false, the antecedent must be so likewise. Thus we gain the law of the mood, which is this: If the consequent is denied, there may be inferred the contradictory of the antecedent. The minor premise, therefore, is any proposition expressing an absolute denial of the consequent: the conclusion is any proposition expressing an absolute denial of the antecedent. In applying these rules to common terms, we have to bear in mind the rules of opposition. "If X is Y, X is Z; but X is not Z: therefore X is not Y." "If no X's are Y's, all X's are Z's; but some X's are not Z's: therefore some X's are Y's." "If some X's are Y's, some B's are Z's; but no B's are Z's: therefore no X's are Y's."

(3.) No conclusion can be drawn, with any minor premise, from either of the other two assumptions which are possible; the affirmation of the consequent, the denial of the antecedent. Neither of these assertions would affect the character of the major premise as an inference.

(4.) All hypothetical syllogisms may be reduced to categorical. The positive mood falls directly into the first figure, the amotive mood into the second. Our second example in the first mood might easily be resolved, thus, into *Celarent*: "Any X's which are Y's are not any Z's; but all X's are some X's which are Y's: therefore no X's are any Z's." Often, however, the categorical expression of the major premise becomes extremely unwieldy. In these cases the books, both English and foreign, advise the substitution of such unanalytic forms as those adopted in the following reduction, into *Camestres*, for the last example under the second mood: "All cases in which some X's are Y's, are some cases in which some B's are Z's; the present case is not any case in which some B's are Z's: therefore the present case is not any case in which some X's are Y's."

Analysis of the hypothetical syllogism.

110. Lastly, however, the frequency of such difficulties, in the reduction of hypotheticals, points significantly to inadequacy of the merely formal analysis. Other circumstances strengthen the suspicion.

The two syllogisms last treated exemplify an instructive distinction.

In the former of these, the conjunctive premise is, in effect, an *enthymeme*; and if for it there were substituted the missing premise, our given minor and conclusion would form with it a simple categorical syllogism: "No Y's are Z's; all X's are Y's: therefore no X's are Z's." But this is nothing more than explicating fully the conjunctive premise itself. There is no difference, logically appreciable, between the argument just set down, and this other: "If no Y's are Z's, and if all X's are Y's, no X's are Z's." Indeed, if we take up our ground very firmly, it may become probable to us that the latter form, as enunciating merely the relation of antecedent and consequent, is the precise and proper logical expression of the argument; that the former ex-

presses too much, in respect that it seems to assert the truth of the antecedent, an assertion which does not logically come into question. In truth, as has already been shown, categorical predication and inference rest on presuppositions. In actual thinking, we have, or endeavour to find, positive reasons, justifying the throwing of our thoughts into the categorical form. But logic is indifferent to these reasons: it accepts the assumptions as given; and it traces them to their consequences at the risk of those who give them.

But, again, the last of our examples exhibits another relation. The terms of the conjunctive premise are four; the inference which it alleges must be a complex inference, for the explication of which materials are not given. Some logicians are inclined to refuse to such propositions the character of genuine hypotheticals; but this denial rests on a narrow view of the process.¹ It is quite conceivable that we should make such an assertion as this: "If all good actions are self-rewarding, there are men who are independent of worldly honours;" and, if the relation between the antecedent and the consequent is admitted, we may argue from this premise, either by position or by amotion. But the relation must be admitted, if the argument is to have any force, or even any meaning; and the character of the data makes it impossible for us to verify the relation, unless we amplify our reasoning by assuming premises which are not given, and which have terms wanting also in our data.

In both of our examples, however, presuppositions are absolutely required. The cases differ only in the amount and kind of these. In neither of them is the hypothetical proposition, as given, sufficient to determine the validity of the inference: it must be assisted, for both, by assumptions throwing us back on categorical forms and categorical laws.

All the doubts converge on one question, suggesting an answer that may be challenged as a paradox. Is there, in a categorico-hypothetical syllogism, any actual inference whatever? Is it really any thing more than the statement of a categorical inference, followed by an assertion (involving no inference at all), that there is an actual case on which that inference bears?

111. As, in hypothetical propositions, the validity of the asserted inference must be assumed; so, in Disjunctives, it must be assumed, first, that the alternatives exclude each other; secondly, that the alternatives given are the only alternatives possible. If either of these assumptions is withheld, we are in the same position as we should be placed in by denying the validity of the hypothetical inference. No conclusion could be drawn from the disjunctive, whatever premise might be taken with it.

Categorico-Disjunctive Syllogisms (oftenest called simply Disjunctive) have two moods, which may be named, with explanation, like those which we have from hypotheticals. The mood in which the conclusion is affirmative may be called the Constructive, or the Mood of Position; that in which the conclusion is negative may be called the Destructive, or the Mood of Amotion. But the introduction of negation into the disjunctive premise, through the alternative, creates a contrariety of relation between the minor premise and the conclusion. When the conclusion is affirmative, the minor premise must be negative; when the conclusion is negative, the minor premise must be affirmative.²

¹ See Mansel, *Prolegomena Logica*, pp. 216, 217. Drobisch (p. 51) holds all hypothetical judgments, and also all disjunctives, to be truly synthetic; and his principle lies at the root of the view here taken of both.

² Hence, as it has correctly been observed, the scholastic names of the disjunctive moods, "*Modus ponens*," and "*Modus tollens*," have not the same aptness as in their other application. The first is properly the "*Modus tollendo-ponens*;" the second the "*Modus ponendo-tollens*."

¹ Mood of Position, the "*Modus ponens*, a positione antecedentis ad positionem consequentis;" Mood of Amotion, the "*Modus tollens*, ab amotione, remotione, vel eversione consequentis ad amotionem antecedentis."

Doctrine of
inference.

All alternatives but one being denied in the minor premise, the remaining alternative must be categorically affirmed in the conclusion: all alternatives but one being affirmed in the minor premise, the remaining alternative must be categorically denied in the conclusion. These assertions are, for the two moods, rules governing all cases in which the conclusion can be categorical. If the affirmations or denials of the minor premise were to fall short of exhausting all the alternatives but one, the conclusion must be disjunctive; and the argument would thus be taken out of the class of inferences here in question.

The rules are easily traceable to the law of non-contradiction, in its application to the simplest case that can yield real inference. Let there be given two names of thinkable objects, B and C. There is then possible the disjunctive assertion: "Either B is C, or B is not C." Since B cannot be both C and Not-C, it follows, first, that, if B is not Not-C, it must be C; next, that, if B is C, it is not Not-C. The introduction of a third object would give a positive term, as D, which must be thought as equivalent to Not-C, that is, as being contradictory of C. "B is either C or D: if B is not C, it must be D: if B is C, it cannot be D." When the given alternatives are more than two, the principle must still be strictly adhered to. Any one alternative, or group of alternatives, being affirmed or denied in the minor premise, all the others must be held as together constituting the contradictory of that alternative or group. All the varieties of combination which many alternatives make possible, must be treated in the same way. Thus, let the given major premise be this: "B is either C, or D, or E." For categorical conclusions, we must fix on some one alternative, and exclude from it all the rest. Affirmatively we may conclude "B is neither C nor D; therefore B is E." negatively, "B is either C or D; therefore B is not E."

Analysis
of the dis-
junctive
syllogism.

112. The books do not attempt the reduction of disjunctive syllogisms into categoricals, unless by first reducing them to hypotheticals, through change of the disjunctive premise. The change to be made on it is dictated by the character of the other premise. Thus, for the first example just given, the major premise would pass into the hypothetical proposition, "If B is neither C nor D, it is E:" for the second example, it would take this shape: "If B is either C or D, it is not E."

This reduction, through hypotheticals, not only leads us back towards categorical forms, but likewise exhibits clearly the principle of the reasoning. It exposes, further, the character of the antecedent process through which, when the terms are common terms (the only case deserving minute inspection), the disjunctive proposition has come into existence. Our last proposition of the sort is equivalent to the assertion, that the class B is constituted by the sub-classes C, D, and E; that "all" the objects we call B are contained in three sub-classes, to which, severally and exclusively of each other, we give the names C, D, and E. What, in this view, is the minor premise? More particularly, what is its subject? Its subject is, "Some or certain B's;" or, "the B's we are thinking of." If the premise is affirmative, it is a direct subalternate of the major premise. It affirms that the B's in question are contained in one of the sub-classes, as C; or, alternatively, that they are included either in one or another of them, as C or D. It follows, inevitably, in the conclusion, that the B's in question are excluded from one and all of the sub-classes co-ordinate to those in which those B's have been included. If, again, the minor premise is negative, the conclusion is gained on the same principle. The B's in question, being excluded from certain of the sub-classes, must be included in some one of the others;

tionem:" the second is the "Modus ponendo-tollens; a positionem ad motionem."

and, if they have been excluded from all the sub-classes but one, they must be included in that one.

Doctrine of
inference.

In short, the disjunctive syllogism, like the hypothetical, sets forth, in its major premise, the result of an antecedent process; and it adds to this, in the minor premise, an assertion of fact. The hypothetical sets forth a pre-formed inference; the disjunctive sets forth a pre-formed ordination of terms, issuing in a logical division. But the latter goes further than the former: it does seem to be a real inference. It silently assumes a premise which is formulated in the expression of the law of excluded middle ("B is either C or Not-C, and cannot be both"); or in the rule of predication thence derived, that co-ordinate terms must be denied of each other. Thus, the ordination and division explicated in the major premise being presupposed, our last two examples are analyzable into these categorical forms: (1.) All B's which are neither C's nor D's are E's; certain B's are B's which are neither C's nor D's: therefore certain B's are E's (*Barbara* or *Darii*). (2.) B's which are either C's or D's are not E's; certain B's are B's which are either C's or D's: therefore certain B's are not E's (*Celarent* or *Ferio*).

DIVISION II.—INFERENCE FROM PREMISES INVOLVING ULTRA-SYLOGISTIC SUBSUMPTIONS.

113. The name *Sorites* is given to a complex argument, The structure and rules of the *Sorites* are resolvable, by expression of steps implied, into a series of simple syllogisms, in which the conclusion of each but the last becomes a premise in the next following.¹ It is needless to examine any of its kinds, except that in which all the propositions are categorical.

The *sorites* may take, by two several arrangements of the propositions, either of two forms. The one is the Direct, common, or Aristotelian; the other the Reversed, or Goclenian.² The rules of either are readily gained from those of the other. The first of the two may serve as our model: it is both the more commonly treated, and by much the more natural.

The following argument exemplifies the Direct *Sorites*: "A is M; M is N; N is P; P is Q; Q is B: therefore A is B." The last proposition is the only one presented as a conclusion: all the others appear as premises. The predicate of each premise, except the last, becomes the subject of the next premise: the conclusion has for its subject the subject of the first premise, for its predicate the predicate of the last.

The *sorites* is resolvable into a number of simple syllogisms, less by one than the number of its premises. Thus, our example, having five premises, yields four syllogisms. Of these, again, the *sorites* expresses no conclusion, except that of the very last, which becomes the conclusion of the *sorites* itself: it expresses no minor premise, except that

¹ *Sorites* (from *σώρξ*, a heap), cumulative argument. "Quemadmodum Soriti resistas? quem, si necesse sit, Latino verbo liceat *Acervalem* appellare: sed nihil opus est." (Cicero, *De Divinatione*, lib. ii., cap. 2.) The Germans call it the "chain-syllogism" (*Kettenschluss*). Most of them, also, give the name of "syllogistic-chain" (*Schlusskette*) to a form of argument which requires only a passing notice, that which the old logicians usually called the *Epicheirema*. It is a syllogism in which one or both of the premises are enthymemes; as this: "M is P (because M is C): S is M (because S is D): therefore S is P." The parenthetical assertions evidently exercise no influence on the conclusion: they are given only as reasons for admitting the premises. If a complete explication of the argument were required, we should have to construct two other syllogisms by supplying the missing premises, "C is P" and "D is M." These "prosyllogisms" being set down side by side, there might be placed below them, as "episyllogism," the given syllogism, with its premises freed from their enthymematic supplement.

² From Goclen or Goclenius of Marburg, who, about the end of the sixteenth century, first analyzed it.

Doctrine of the first syllogism, which is the first proposition of the inference. sorites: all the other premises are majors.

The extricated syllogisms of our example are the following; and in these it is observable, that the subject of the conclusion passes on as the subject of each minor premise.

1. M is N; A is M: (∴ A is N.)	2. N is P; (A is N): (∴ A is P.)	3. P is Q; (A is P): (∴ A is Q.)	4. Q is B; (A is Q): ∴ A is B.
---	---	---	---

The rules of the sorites are readily deducible from this analysis.

(1.) All the constitutive syllogisms must be in the First Figure.¹ When the conclusion is negative, the second figure is reachable, but only through conversions; and when the conclusion is in A, all the indirect figures are plainly inapplicable.

(2.) Only one Premise can be Particular; and that must be the first of the expressed series. The reason is evident. All the others are major premises; and, in the first figure, the major must be universal.

(3.) Only one Premise can be Negative; and that must be the last of the expressed series. If any other were negative, the suppressed conclusion of its syllogism must be negative. But this conclusion becomes the suppressed minor premise of the next syllogism; and that premise must, in the first figure, be affirmative.

(4.) The Conclusion of the sorites may be an A, when all the premises are A: it may be an I, when the first premise is I, and all the others A: it may be an E, when the last premise is E, and all the others A: it may be an O, when the first premise is I, the last E, and all the others A.

The Reversed Sorites differs from the Direct in the order of the premises only, which is exactly transposed. The same example, so treated, stands thus: "Q is B; P is Q; N is P; M is N; A is M: therefore A is B." Here the subject of each premise but the last becomes the predicate of the next; the conclusion takes its subject from the last premise, its predicate from the first. The premises now expressed are the minors of the constitutive syllogisms, excepting the first premise, which is a major. The only changes which the rules of the common sorites undergo are these; that the premise which may be particular is the last, that which may be negative the first.

The extricated syllogisms are the following. The series is necessarily different from that yielded by the other form; and the predicate of the conclusion does duty as predicate of each major premise.

1. Q is B; P is Q: (∴ P is B.)	2. (P is B); N is P: (∴ N is B.)	3. (N is B); M is N: (∴ M is B.)	4. (M is B); A is M: ∴ A is B.
---	---	---	---

Analysis of the categorical sorites.

114. The dissection of the sorites into simple syllogisms is not necessary. If it is accepted as given, the force of the reasoning is quite as evident as the dissection could make it; while the process may still more easily be referred to a higher principle.

Suppose (and the case is supposable, though not more), that, in an argument as complex as that in the example, all the terms are singulars. Each affirmation is then an assertion, that subject and predicate are but two names for one and the same individual object. Quantity not being in question, the quality of the propositions is the only point to be considered. Evidently the rule of the direct sorites holds: negation is admissible only at the last step. If it intruded earlier, the chain of identities would be broken; and any further assertions of identity would have no bearing on those that had preceded.

If the terms are common terms, the same principle is applicable, with this limitation only: that our affirmations are now assertions of inclusion, ("All A's are some M's"); while our negations are assertions of exclusion, ("The Q's are not any B's"). The antecedent of our thinking, the term whose relations are in question, is A, the subject of the conclusion. The common sorites (in this, as in most other points, an apter development of the argument than the other), deals with this term by a regular process of generalization. It begins by asserting the inclusion of A in the class M, that is, its identity with some of the M's: it next includes this class M in the wider class N; N in the wider class P; P in the wider class Q; and Q in the wider class B. Hence follows necessarily the inclusion of A in B, the widest of all the classes, that is, the identity of A with some of the B's.

The affirmative sorites does, in fact, nothing else than explicate, step by step, the affirmations implied in a series of terms positively pre-ordinated in extension thus, from highest to lowest: B, Q, P, N, M, A. Of each subordinate term, its superordinate may be affirmed universally: of the lowest of all the terms, A, the highest, B, may be so affirmed. The syllogisms, evolvable out of the common sorites, trace the A, stage by stage, from lower class to higher. But the case is parallel to that, already observed on, of the supposed suppression of the minor premise in a simple syllogism: the evidence which supports the reasoning is in as little need of the minute explication here as there.

The rules show themselves spontaneously, when the argument is regarded in the aspect just described. If our antecedent is "some A's," then of "some A's" only, throughout the process, can either affirmation or denial take place: the first premise is particular; so must be the conclusion. It is equally manifest that no premise but the first can be particular. The inclusion of a term in a class would avail us nothing, unless we were able, in our next step, to include the whole of that class in the next higher. Again, if negation is introduced at any step before the last, the chain of the positive ordination has snapped. In asserting, for instance, not that "the N's are P's," but that "the N's are not P's," we should pass from the series of terms with which we began, A, M, N, into a new series, P, Q, B, of whose relations to the first series we know nothing. At our last step the crossing of the frontier is safe; because our journey is at an end. Instead of asserting that "the Q's are B's," we might assert that "the Q's are not B's;" whence it would follow that the A's, already identified with some of the Q's, are not B's.

The clue thus furnished would make the scrutiny of the Reversed Sorites very instructive. Its assertions proceed in the order of specification; but they necessarily oscillate. They must do so in order that,—while they began by asserting something of Q, the highest of the subordinate terms,—each lower term in its turn may, through a higher, be directly connected with the superordinate B, till the lowest specification is reached, and A brought into relation with B.

The evolved syllogisms of the two forms bring up curiously, too, the bearings of the two wholes of the concept. The direct sorites is evolved through repeated dealing with A, as an object or objects to be referred to classes till it reaches B. The reversed sorites is evolved through repeated dealing with B, as an attribute to be predicated of object after object, till at last it becomes possible to predicate it of A. The former proceeds in extension, the latter in comprehension.

DIVISION III.—INFERENCE BY COMBINATION OF COMPLEX MODES.

115. The complex forms of predication and reasoning

The mixed sorites and the dilemma.

¹ See, however, as to this question, Lambert, *Neues Organon*, i., p. 188-190; Twisten, *Logik*, pp. 133, 138; Bachmann, *Logik*, p. 254; Drobisch, *Neue Darstellung*, pp. 116-124.

Doctrine of which have now been examined, admit various combinations, inference. which have been, by many logicians, scrutinized with great patience and sagacity. But the theory of them cannot be said to be perfect; and they are certainly curious rather than useful. All of them carry us, by a greater or less distance, still further away from that direct comparison of terms, which, as expressed in categorical propositions, we have had to accept as the normal form of explicative thinking.

It must here suffice to point out, very generally, some of the most prominent among those complexly complicated shapes of reasoning.

I. A Sorites may be constructed with propositions all of which are Hypothetical. Or all its premises may be Hypothetical, except the last: this premise being Categorical, so will be the conclusion.—To the Disjunctive Sorites, almost all logicians have refused admission; and rightly. It is quite possible; but, yielding nothing except a growing congeries of alternatives, it expresses only a deeper and deeper plunging into doubts.

II. The very complex argument, called the Dilemma, has a celebrity which claims for it somewhat closer attention. When expressed so as to bring out all its elements, it is describable as being an Hypothetico-Disjunctive Syllogism. Its major premise is an hypothetical proposition, one of whose constitutive propositions (either antecedent or consequent) is categorical, the other disjunctive. The minor premise is in form disjunctive, and may be either affirmative or negative. (1.) The minor premise may affirm, exhaustively, the disjunctive proposition of the major; and, in this case, the conclusion affirms the categorical proposition of the major. But this inference is valid only when the major premise has its categorical proposition as consequent. (2.) The minor premise may deny, exhaustively, the disjunctive proposition of the major; and in this case the conclusion denies the categorical proposition of the major. This inference is valid only when the major premise has its categorical proposition as antecedent. In short, there are thus two moods, corresponding in character to the constructive and destructive moods in hypotheticals. The argument may be analyzed and tested as an hypothetical.

The following are examples.—1. (*Major*) If either A is B, or E is F, then C is D; (*Minor*) Either A is B, or E is F: (*Conclusion*) Therefore C is D.—2. If A is B, then either C is D, or E is F; but neither C is D, nor E is F: therefore A is not B.¹

¹ Thomson, *Laws of Thought*, p. 267; Fries, *System*, p. 61. The name of Dilemma is by some logicians used more widely than here: by others it is perversely limited to the sophistical arguments spoken of in the next paragraph. The name was most probably applied to this kind of inference, to intimate the compound character of the disjunctive assumption (ἀντίθεσις). The argument was also called by the Latins the “*syllogismus cornutus*,” whence the phrase of “placing one on, or between, the horns of a dilemma.” The word Dilemma supposes two alternatives only: if the alternatives are more than two, the argument is properly a Trilemma or Polylemma. There are three alternatives in the first of the following examples. “A chess-player may argue thus: Whether I move my king, or cover him, or take the piece which has given him check, I must be checkmated at the next move; but I must do one or another of the three things: therefore I must be checkmated at the next move.” (Drobisch, p. 111.) “If man is incapable of

The Greek dialecticians prided themselves on the exhibition of dilemmas which they alleged to be insoluble. These were arguments so framed, that it is necessary to admit both the affirmative minor premise and the negative, and thus to reach both of two contradictory conclusions. All such arguments must, of course, have a fallacy somewhere. Several of the ancient examples are constructed so dexterously, that the detection of the flaw is difficult; but it is always possible, while often there are more flaws than one.—In the first place, the arguments are sometimes not given in the form just described; and, when their propositions are examined, it is found that they cannot be thrown into that form, or into any other that guarantees any conclusion. In such cases, the fallacy is formal, and logically discoverable. Next, if a genuine form is given or attainable, the admission of the conclusion, as a logical consequent of the premises, leaves the argument worthless, unless there have concurred three conditions, all material or extralogical. (1.) The disjunctive proposition of the major must be a genuine disjunctive: its alternatives must be both exclusive and exhaustive. Here, more probably than elsewhere, will be found the weakness of a sophistical dilemma: either it ignores some alternative thinkable under the terms; or it asserts, as mutually exclusive, cases which are reconcilable. (2.) The inference, hypothetically stated in the major, must be valid, either *ex facie* or through extraneous suppositions. (3.) The assertion of fact made in the minor premise must be admitted as true.¹ (W. S.)

improvement, he must be either a divinity or a brute; but man is neither the one nor the other: therefore man is not incapable of improvement.” (Troxler, ii. 103.)

¹ It may be worth while to illustrate, by two of the most famous among the ancient examples, the complications through which it was attempted to veil the weak points of sophistical dilemmas.

The first is known as the “*Syllogismus Crocodilinus*.”—A crocodile, having seized an infant, promises to give it back if the mother will say truly what is to happen to it. She, perhaps rashly, asserts, “You will not give it back.” Thereupon both parties play the sophist. The crocodile argues thus: “If you have spoken truly, I cannot give back the child without contradicting your assertion; if you have spoken falsely, I cannot give it back, because you have not fulfilled the agreement: therefore I cannot give it back, whether you speak truly or falsely.” The mother replies: “If I have spoken truly, you must give back the child in terms of the agreement; if I speak falsely, this can only be because you have given back the child: therefore, in either view, the child must be given back.”

The other example is the “*Sophism of Euathlus*,” which might have been named, quite as fairly, from the other party to the dispute. Neither of them is represented as having been more successful than the crocodile or the mother, in discovering, for the division on which the disjunctive rests, a foundation justly applicable to the facts of the case.—Euathlus had received lessons from Protagoras, the rhetorician, on condition that the fee should be paid if the pupil were successful in the first cause he pleaded. Euathlus delaying to undertake any cause, Protagoras sues him; and this is consequently the young man’s first law-suit. The master argues in this way: “If I am successful in the cause, you must pay me in virtue of the sentence; if I am unsuccessful, you must pay me in fulfilment of the contract.” The pupil retorts: “If I am successful, I am free by the sentence; if I am unsuccessful, I am free by the contract.”

Logrono
||
Loire.

LOGRONO, a walled town of Spain, capital of the province of the same name, stands on the right bank of the Ebro, here crossed by a handsome stone bridge, 65 miles E. by N. from Burgos. It is a well-built town, having a number of churches, convents, and hospitals, a Jesuit college, theatre, and orphan asylum. The chief manufactures are leather, hats, soap, and brandy. Pop. 6843.

LOHEIA, a seaport-town of Arabia, Yemen, on the Red Sea, in N. Lat. 15. 42., E. Long. 42. 43. A few of the houses are built of stone, but the majority of them are mere mud huts covered with grass. The harbour is capacious, but is so shallow that vessels cannot approach within some distance of the town. A considerable trade is carried on in coffee, which, however, is of inferior quality to that of Mocha or Hodeida. Pop. about 4000.

LOIR-ET-CHER, a central department of France, formed from a part of the old province of Orléanais, is bounded on the N. by the department of Eure-et-Loir, on the E. by those of Loiret and Cher, on the S. by that of Indre, and on the W. by those of Indre-et-Loire and Sarthe. It is situate between N. Lat. 47. 12. and 48. 8., and between W. Long. 0. 40. and 2. 15., and has an area of 2389 square miles. This department is divided into two nearly equal parts by the Loire, and is named from its affluents the Loir and Cher, which water it in the N. and S. The Cher receives the Sauldre and the Feuzon; the Loire, the Cosson, and the Beuvron. The Loire, the Loir, and the Cher are the only navigable rivers; the first has on its left bank a great number of small lakes and ponds. Blois, its capital, with 17,749 inhabitants, is situate on the line of railway which runs along the N. bank of the Loire, and connects Nantes with Paris. The mineral wealth of this department is neither abundant nor varied. Gun-flints used to be worked here more extensively than in any other part of France, but the recent invention of percussion-locks for fire-arms has ruined this branch of industry. There are some iron mines; also quarries of alabaster, lime, and potter's clay. The principal manufactures are,—woollen and cotton cloths, leather, gloves, native sugar, earthenware, porcelain, glass, and gun-flints. Agriculture is in a very flourishing condition. The country is generally flat, and in the N. it is exceedingly fertile, producing cereals of all kinds, besides hemp, beet-root, and red and white wines. The trade of the department is much facilitated by the Cher Canal: corn, wine, brandy and wool are the principal articles of commerce. It has three arrondissements, subdivided as follows:—

	Cantons.	Communes.	Pop. in 1851.
Blois	10	138	131,817
Romorantin	6	48	50,522
Vendôme	8	110	79,553
Total	24	296	261,892

LOIRE, a department of France, comprising the old province of Forez, with parts of Beaujolais and Lyonnais, is bounded on the N. by the department of Saône-et-Loire, on the E. by those of the Rhône and Isère, on the S. by those of Ardèche and Haute-Loire, and on the W. by those of Puy-de-Dôme and Allier. It is situate between N. Lat. 45. 13. and 46. 17., and E. Long. 3. 40. and 4. 45., and has an area of 1834 square miles. This department, forming the basin of the River Loire, which flows through its centre, is inclosed on the E. and W. by offshoots from the group of the Cevennes Mountains. The highest point in the department is Mont Pilat, 3985 feet above sea-level. A small portion of the S.E. is drained by the Rhone. This river and the Loire are the only navigable ones in the department. A railway runs from Roanne to St Etienne, and thence to Lyons. The coal-fields occupying the high ground on the E. are of great value and extent; they furnish annually a third of the entire coal raised in the kingdom. Mines of lead and iron are also worked. The manu-

Loire.

factures are extensive and important. The principal are silk, cotton, and linen. Machinery and fire-arms are produced in great abundance. The soil, sandy and clayey in Montbrison and Roanne, and granitic in St Etienne, is not in general fertile. Agriculture, accordingly, is not in a very advanced state. The corn and wine are not equal to the local consumption. Horses and cattle are inferior; the sheep are small, with coarse wool, but very agreeable flesh. There are also extensive forests of pine, beech, and oak. The department is divided into three arrondissements, which are subdivided as follows:—

	Cantons.	Communes.	Pop. in 1851.
Saint-Etienne.....	9	74	205,148
Montbrison	9	138	132,116
Roanne.....	10	109	135,324
Total.....	28	321	472,588

The chief town is St Etienne, with a population (1851) of 56,000.

LOIRE (Haute), a department of France, which takes its name from its position on the upper part of the basin of the River Loire. It is formed of part of Languedoc (the old district of Velay, Vivarais, and Gévaudan), with portions of Auvergne and Forez, and is bounded on the N. by the departments of Loire and Puy-de-Dôme, E. by those of Loire and Ardèche, S. by those of Ardèche and Lozère, and W. by that of Cantal. It is situate between N. Lat. 44. 40. and 45. 25., and between E. Long. 3. 4. and 4. 26., and has an area of upwards of 1920 square miles. Lying along the N. slope of the Cevennes, the surface is exceedingly mountainous and irregular. It is traversed by the mountain chains of Velay and Forez, which are for the most part volcanic. The W. of this department is drained by the River Allier; the E. and the centre by the Loire, and its tributaries—the Gazeille, the Lignon, and the Soume on the right; and the Borne, the Arzon, and the Ance on the left. The mineral wealth of the district is not great; yet there are two coal mines in the canton of Auzon of some value, and lead and antimony are also worked. The industrial manufactures are considerable, consisting mainly of lace, ribbons, linen, and woollens. Two-thirds of the population are engaged in this way. There are also tanneries, brick and tile works, and potteries. A considerable number are engaged in felling timber in the forests, which is sawn into planks, and floated down the Allier. Agriculture is in a backward state; the soil is generally barren, the climate severe, and, in the uplands especially, cultivation is almost impossible. Nevertheless, the growth of corn and potatoes is equal to the consumption. Wine, however, is scarce, and of an inferior quality. A great number of horses and mules are reared, and Mezcenc is noted for dairy produce and honey. The principal town is Puy, with a population of 15,723 inhabitants. The department is divided into three arrondissements, which are subdivided as follows:—

	Cantons.	Communes.	Pop. in 1851.
Puy.....	14	111	134,430
Yssengeaux.....	6	39	87,161
Brioude.....	8	106	83,024
Total.....	28	256	304,615

LOIRE-Inférieure, a department of France, situate, as its name indicates, at the embouchure of the River Loire, on the W. coast of that country. It comprises the S.E. extremity of the old province of Bretagne; is bounded on the N. by the department of Ile-et-Vilaine and Morbihan, on the E. by those of Mayenne and Maine-et-Loire, on the S. by that of Vendée, and on the W. by the Atlantic Ocean. It is situate between N. Lat. 46. 53. and 47. 50., and between W. Long. 0. 55. and 2. 32., and has an area of 2595 square miles; is traversed by the Loire from E. to W., and divided by it into two unequal portions, the larger lying

Loire
||
Loiret.

to the N. The most important towns of this department—Ancenis, Nantes, and Paimbœuf—are situate upon the Loire, the affluents of which in this department are very numerous; the more important are,—the Erdre, on the right or N. side, which has its embouchure at Nantes; the Sevre-Nantaise and the Achenau on the left. The Achenau is connected with Grandlieu, the largest lake in France, and the N. tributaries drain the numerous small lakes and extensive bogs and marshes of that district. The Vilaine borders on the department on the N.W. There is a canal between Nantes and Brest; and the former town, the capital of the department, is connected with Paris by a railway through Angers, Tours, and Orleans. The minerals are considerable; the principal being salt, iron, coal, granite, and kaolin. Agriculture is in a more flourishing condition here than in any other part of Bretagne. It is rich in grain, especially rye and buckwheat; and common white wine is produced in great abundance. Cattle of the Breton breed are reared in the rich meadows and pasture-lands along the Loire; also horses, swine, and sheep. Here, as elsewhere in Bretagne, great attention is given to the nurture of bees. The commerce, of which Nantes (pop. 96,000) is the centre, is very extensive; the chief articles of which are grain, wine and spirits, timber, fish, and salt. There are five arrondissements in this department, subdivided as follows:—

	Cantons.	Communes.	Pop. in 1851.
Nantes.....	17	71	240,440
Ancenis.....	5	28	48,102
Châteaubriant.....	7	37	71,462
Paimbœuf.....	5	25	46,766
Savenay.....	11	51	128,893
Total.....	45	212	535,664

LOIRE, LA (anc. *Liger*), the longest river in France, rises at the foot of Gerbier des Joncs, among the Cevennes Mountains, in the department of Ardèche, and after a westerly course of 540 miles, falls into the Bay of Biscay. This river drains a district of France nearly equal in extent to one-fourth of the entire kingdom. It becomes navigable at Roanne, and passes the flourishing towns of Orleans, Blois, Tours, Saumur, and Nantes. The navigation is interrupted, however, during four or five months in the year, by frost or floods. To obviate some of the difficulties incidental to the navigation of this river, a lateral canal has been formed along a part of its course, extending from the Canal du Centre to the Canal de Briare. The Loire communicates with the Rhone and Seine by means of canals. The affluents of this river are very numerous and important; many of them navigable. Those on the right are,—the Arroux, the Nièvre, the Maine (formed by the union of the Mayenne and the Sarthe); on the left the Alliet, the Loiret, the Cher, the Indre, the Vienne, the Thoué, and the Sevre-Nantaise. To prevent the Loire from spreading over the low grounds along its course, it has been banked in by dykes, built much above its ordinary level. These embankments were never known to give way previous to the great floods of 1846. They gave way at the same place during the fearful inundations of June 1856, carrying away the bridge and village of Savonnières, and inundating the communes of La Riche-extra and La Chapelle-aux-Naux, causing a dreadful loss of life and property. The mouth of the river is about 7 miles wide, measured from St Nazaire to Paimbœuf. Ships find great difficulty in taking the mouth of the river, owing to the exposed nature of its position, and to the numerous sandbanks which traverse it.

LOIRET, a department of France, formed from the old province of Orléanais (Orléanais proper, Gâtinais, and Sologne), and a small part of Berry. It is bounded on the N. by the departments of Seine-et-Marne and Seine-et-Oise, on the E. by that of Yonne, on the S. by those of Nièvre, Cher, and Loir-et-Cher, and on the W. by those of Loir-et-Cher and Eure-et-Loir; and is situate between the

parallels of N. Lat. 47. 30. and 48. 30., and the meridian of Paris passes through it. It has an area of 2551 square miles. The surface is partly flat, and partly undulating, and is almost destitute of hills, with the exception of a low ridge in the E., forming the watershed of the rivers Seine and Loire. The latter river traverses the department from E. to W., and divides it unequally. It receives as a tributary the Loiret, which gives its name to the department. The other streams are the Loing and the Essonne. The water communication is rendered very complete by the canals of Orleans, Loing, Briare, and the lateral canal of the Loire. The number of small lakes and ponds is very great—nearly 800 in all. The mineral wealth of Loiret is not great, being confined principally to lime, building stone, marl, and potter's clay. Manufactures have made little progress, and have fallen off considerably of late, especially at Orleans. More than half of the department is arable, and remarkably fertile: the N. particularly so, forming part of *the garden of France*. The chief crop is wheat; saffron also is much grown; and wine is abundant. The forests of Orleans and Montargis are extensive. Cattle are very good, and the breed of sheep is improving. Bees are much attended to. There is an important trade in corn, wine, spirits, fruits, fish, honey, saffron, wool, cattle, and timber.

The capital is Orleans, with a population of (in 1851) 47,393. This department is divided into four arrondissements, which, with their subdivisions, are as follows:—

	Cantons.	Communes.	Pop. in 1851.
Orleans.....	14	106	154,600
Gien.....	5	49	49,162
Montargis.....	7	95	76,434
Pithiviers.....	5	98	60,833
Total.....	31	348	341,029

LOJA, a town of Spain, province of Granada, situate in a deep and beautiful valley, through which flows the Genil, here crossed by a Moorish bridge, 25 miles W.S.W. of Granada. The situation is very steep, and the streets are very irregular. The castle stands on a rock in the centre of the town, which, from being the key to Granada, was once a place of great military importance. The town is still in a thriving condition, and carries on manufactures of coarse woollens, silks, paper, and leather. Pop. about 14,000.

LOKEREN, a town of Belgium, province of East Flanders on the right bank of the Drume, and on the Ghent and Antwerp Railway, 12 miles E.N.E. of the former town. The houses are generally large and commodious, and the streets wide and regular; and altogether the town has the appearance of a "large, quiet, Flemish village." The market-place is large and handsome; and among the public buildings are—a spacious church surmounted by a tower, a town-house, prison, and hospital. Its linen fabrics are celebrated, and it has also manufactures of cotton goods, flannels, lace, leather, tobacco, &c. It also carries on an active trade in its manufactures and agricultural produce. Pop. (1851) 16,470.

LOKMAN, a philosopher mentioned in the Koran, is said to have been born about the time of David. One tradition represents him as a descendant of the Arab tribe of Ad, who, on account of his piety and wisdom, was saved when the rest of his family perished by divine wrath. According to another, he was an Ethiopian slave, noted alike for bodily deformity and a gift for composing fables and apologues. This account of Lokman, resembling so closely the traditional history of Æsop, together with many traits common alike to both these fabulists, has led to the prevalent opinion that they were the same individual. The various reports agree in ascribing to Lokman extraordinary longevity. His extant *Fables* bear evident marks of modern alteration, both in their diction and their incidents. They were first published with a Latin translation of the Arabic, by Erpenius (Leyden, 1615). Galland produced a French translation of the *Fables* of Lokman and Bidpai, or Pilpay,

Loja

Lokman.

Lollards. at Paris in 1724. The latest editions of Lokman are those of Caussin, Paris, 1818; Freytag, Bonn, 1823; and Rödiger, Halle, 1830.

LOLLARDS, THE, a religious sect, made their first appearance about the beginning of the fourteenth century. Among the various opinions touching the origin of their name, the most common is that which traces it to Walter Lollard, who was burnt for heresy at Cologne in 1322. Without doubt, however, he, instead of giving, owed his surname to the sect. The correct opinion is, that the Lollards received their distinctive title from their marked attention to the worship, and especially to the praise of God. From the German word *lullen*, *lollen*, or *lallen*, meaning "to sing in a low tone," they were called *Lullhards*, *Lollhards*, or *Lollards*. Their habit of frequent prayer was the cause of their other title, *Beghards*, derived from *beggen*, to "beg" or "beseech." The term Lollards was often applied to sects known by other appellations, amongst which the most noted were the *Cellites*, or *Alexians*, of Antwerp. These, during the raging of a virulent pestilence, tended the couch of the dying which the priests had forsaken, and accompanied the dead to the grave, chanting as they went their usual mournful melodies. To the same humane duties did the Lollards of both sexes, over the greater part of Germany and the Netherlands, devote their lives, trusting for their livelihood to the benevolence of the pious, and to the gratitude of those whom they relieved. The priesthood, vexed that their indolence had become so apparent by contrast with such active benevolence, keenly persecuted the Lollards, and arraigned them before the pontiffs for many faults and errors. Fastening upon the vices of some mere formalists who had joined the sect, they laid the hollow deceit of a few to the charge of all, and, in the course of time, applied the term Lollard as an epithet of contempt and reproach to all whom they considered hypocritical. The magistrates, however, appreciating the public services of the Lollards, advocated their cause with the pontiffs, and obtained for them a withdrawal from the jurisdiction of the Inquisition to that of the bishops alone. This freedom from molestation was perfected in 1472, when Charles Duke of Burgundy procured a decree from Sixtus IV., absolving the Lollards from the authority of the bishops, and constituting them a religious order. Additional privileges were conferred upon them in 1506 by Julius II. Many of their societies existed in Antwerp, Cologne, and Utrecht; and, according to Trithemius, their number in Germany amounted to 80,000.

The term Lollards, from being fixed as a stigma upon all those who simply disavowed ecclesiastical practice, came to be applied to those also who denied ecclesiastical doctrine. Accordingly, Walter, above mentioned, received his surname of Lollard on account of his rejection of the mass, extreme unction, and penances, and also, it is said, of baptism and repentance. For a similar reason, and not because, as some suppose, they came from Germany, the followers of Wickliffe in England were called Lollards. Their chief heresy was the denial of the Roman Catholic doctrine, that unbaptized infants must necessarily perish; and accordingly when Henry IV. enacted the statute concerning the burning of heretics this tenet was appointed the test for all suspected of Lollardism. Countenanced by many of the nobility, who concealed their envy of the wealth of the priesthood under the mask of zeal for church reform, the Lollards increased in numbers and in confidence. At the beginning of the reign of Henry V. they affixed placards at the different church doors in London, threatening to shake off by force the load of persecution under which they had so long groaned. Following up this menace, they mustered an army of about 20,000 under their leader, Lord Cobham, but were speedily dispersed by the prompt conduct of the king, and were afterwards kept under check by additional

enactments. The Council of Constance, by removing many of the most glaring ecclesiastical abuses, caused a reaction in favour of the church, and thus weakened the strength of the Lollards. Yet this sect, still attracting within their pale all those who longed to lay their hands upon the ecclesiastical patrimony, continued to weather the storms of persecution that at intervals assailed them, and in the reign of Henry VIII. were the first to adopt those reformed doctrines that finally removed all distinction between them and the rest of the nation. Previous to this period, however, it is calculated by Fox that more than 100 of their number were burnt at the stake.

LOLLI, ANTONIO, a celebrated violinist, was born at Bergamo, in the N. of Italy, in 1728, according to some authorities; or in 1733, according to his pupil, Michel Woldemar. He appears to have been a self-taught violinist. About 1760 he travelled in the Netherlands and in Holland, and went thence into Germany. He visited St Petersburg in 1773, and Paris in 1789, where his extraordinary command of the violin excited much attention. He performed in London in 1785, where he was considered as a madman, but soon returned to Italy. After appearing at Berlin, Copenhagen, and Vienna, he visited Palermo in 1793, and Naples in 1796. He died at Palermo in 1802. The conquest of difficulties seems to have been his chief ambition, and he is said to have had no feeling for measure in his playing. Besides his sonatas and concertos, he published a *School for the Violin*, with accompaniments for a second violin, viola, and bass. Lolli, like some other violinists of his time, often altered the tuning of his violin in order to execute certain passages, or to obtain particular effects. Some writers, unacquainted with the compositions of Lolli and other violinists of the last century, have wrongly ascribed to Paganini alone the artifice of altering the tuning of the violin for purposes of effect, or of execution.

(G. F. G.)

LOMBARD, PETER, surnamed *Master of the Sentences*, the son of obscure parents, was born at a village near Novara, in Lombardy, about the beginning of the twelfth century. After receiving his elementary education at Bologna, he removed to France, bearing a recommendation to St Bernard, by whom he was placed at the famous school of Rheims. Attracted to the University of Paris by the eminence of its professors, he became so noted there for his attainments, that he was successively appointed tutor to Philip, the son of Louis le Gros, a professor of theology, and, in 1159, Bishop of Paris. He died in 1164. The chief work of Peter Lombard, and that which gave him his surname, is his *Sententiarum libri quatuor* (Nuremberg 1474), being a collection of sentences or passages from the fathers bearing upon the disputed doctrines in theology. By such a concentrated weight of authority, he attempted to quiet all religious doubts and controversies, and to bind the spirit of free inquiry with the bonds of the church's decisions. A contrary result, however, followed. Failing to reconcile the opposing doctrines, contained in different quotations, the book of *Sentences* readily furnished both matter and occasion for controversies, which its timid and faltering speculation failed to decide. It even expressly started difficulties which it never attempted to settle. Yet this work upholding, both by precept and example, the supreme authority of the church in questions of doctrine, and forming the first complete summary of the theology of the middle ages, was employed in the schools as a manual, and became the text-book of numerous and important commentaries. Its greatest merit, however, consists in its having embodied the intellectual spirit of that age, and laid the foundation of the scholastic philosophy. Some of Peter Lombard's views touching the human nature of Christ have been censured, and sixteen of his articles were condemned by the divines of Paris in 1300.

Lolli
||
Lombard.

Lombards. LOMBARDS, or more correctly LONGOBARDS, a northern nation who settled in Italy in the sixth century, and founded a kingdom, which lasted 206 years, 568-774.

The name of *Longobards* is of doubtful origin, some derive it from *lack*, a word signifying winter, whilst others think that it comes from the two German words *langen harden*, or the long halberds they were supposed to use in war. But Paulus Diaconus, their historian, and himself a Longobard, who lived in the eighth century, tells us that they were called Longobards from the length of their beards, having formerly been called Winili:—“*Certum est Longobardos, ab intactæ ferro barbæ longitudine, cum primitus Winili dicti fuerint, ita postmodum appellatos. Nam juxta illorum linguam, lang longam, baert barbam significat.*” (*De Gestis Longob.* i. 9.) Possibly they may have received this name on their first arriving among the Germanic nations, who wore no beard.

Scanty, and often contradictory, are the earliest records of the Longobards, until they settled on the Danube, in the time of Odoacer. They are supposed to have left Scandinavia at an unknown period, under the conduct of their chiefs, Ibor and Aion, and after attacking and overcoming the Vandals, to have settled in the N. of Germany. Velleius Paterculus, who attributes to them more than German ferocity, states that they were conquered under Augustus by Tiberius Cæsar; and Strabo and Ptolemy mention them as established on the right bank of the Elbe, and forming part of the confederation of the *Suevi*. Tacitus adds, that, being few in number, and surrounded by powerful neighbours, they maintained their independence by constant warfare. Ibor and Aion were succeeded by Agilmund, who is commonly reckoned the first king of the Longobards.

Towards the end of the fifth century they settled on the left bank of the Danube, in the country of the Rugians, who had been almost exterminated by Odoacer. During their stay in this country they rendered themselves formidable to the neighbouring nations, and carried on successful wars with the Heruli. In 526 they were allowed by the Emperor Justinian to settle in Pannonia and Noricum, under their king, Audoin. It was here that the enmity which had long existed between them and the Gepidæ broke out into open war. In a great battle fought in 551, Turismund, the son of the king of the Gepidæ, was slain in single combat by the son of Audoin, Alboin, who shortly after succeeded his father as king of the Longobards. The first act of Alboin was to form an alliance with Baian, the chagan of the Avars, in order jointly to attack the Gepidæ, whose country was to be given up to the Avars. In 566 the two allied nations, from different sides, invaded the country of the Gepidæ, whose king, Cunimund, a brother of Turismund, hastened to meet the Longobards, and give them battle. Alboin slew him with his own hand, defeated his army, and killed so great a number of them, that the Gepidæ ceased from that time to be a nation. He cut off Cunimund's head, and had a cup made of his skull, called, in the language of the Longobards, *scala*, which he made use of in all public entertainments. Having, among other captives, taken the king's daughter, Rosamund, he married her after the death of his former wife, Clotsuinda, the daughter of Clothaire, King of the Franks.

By this victory Alboin gained such reputation, that his friendship was courted by Justinian, on whose application 6000 Longobards were sent to the assistance of Narses against the Goths. The success of the Romans in this expedition, and the subsequent invasion of Italy by the Longobards, have been noticed under the art. ITALY. Alboin was slain in his own palace, through the treachery of his wife, on the 28th June 573, being the fourth year of his reign in Italy. As he was one day feasting at Verona, in the height of his mirth he sent for the queen, and filling

the cup which he had made of Cunimund's skull, he commanded her to drink merrily with her father. Rosamund, struck with horror, hurried out of the room, and, incensed against her husband for thus barbarously triumphing over the misfortunes of her family, resolved to make him pay dear for his inhuman and insulting conduct. She discovered her intention to Helmichild, the king's shield-bearer, who suggested that Peredeus, a youth of great courage and bodily strength, should be called into the conspiracy. Peredeus refused to be in any way accessory to the death of his sovereign, and in this resolution he persisted, until, by a shameful stratagem, he was forced to comply with the queen's wishes. Knowing that he carried on an intrigue with one of her ladies, Rosamund placed herself one night in that lady's bed, and received the youth as if she had been his mistress. Then discovering herself to the deceived lover, she told him that he must now either put the king to death, or be put to death by him. Peredeus, knowing that after what he had done, his safety depended upon the death of the king, engaged at length in the treason. One day, therefore, the queen having lulled Alboin to sleep after dinner, introduced Peredeus into his chamber, who fell upon the king with his dagger. Alboin started up and laid hold of his sword, which he had always by him; but having in vain attempted to draw it, the queen having beforehand fastened it in the scabbard, he defended himself with a footstool till he was at last overpowered and despatched with many wounds. Such is the story related by Paulus Diaconus, who adds that he had himself seen the fatal cup of Cunimund's skull in the hands of King Rachis. Agnellus of Ravenna, however, tells the story somewhat differently, as he does not mention Peredeus, and makes Helmichild the deceived lover and unwilling murderer of Alboin.

Rosamund had promised to Helmichild that, as soon as the king was despatched, she would marry him, and bestow upon him the kingdom of the Longobards. The first part of her promise she immediately fulfilled, but she was so far from being able to bestow the crown upon him, that they were both of them obliged to save themselves by flight. They fled to Longinus, the exarch of Ravenna, taking with them the jewels and treasure of the late king, and were received with great marks of friendship and kindness. But Rosamund had not been long in Ravenna, before the exarch, thinking that a favourable opportunity now offered for making himself king of Italy by her means, declared that it was his intention to marry her, provided, by some means or other, she despatched Helmichild. Rosamund, highly pleased with the proposal, resolved to get rid of the person whom she had only married in order to gratify her revenge. Accordingly, having prepared a strong poison, and mixed it with wine, she gave it to her husband as he came out of the bath and called for drink, according to his custom. Helmichild had not half emptied the cup when, by the sudden and strange sensation which he felt in his bowels, he concluded what it was, and with the sword pointed at the queen's breast, compelled her to drink the rest. They both died in a few hours; and Longinus, laying aside all thoughts of making himself king of Italy, sent Albuinda, the daughter of Alboin by Rosamund, and the king's treasure to Constantinople.

The Longobards then chose Clephis, one of the nobility, as their king. He exercised great cruelty on the conquered Italians; but, after a short reign of eighteen months, both he and his wife were murdered by a servant; and there ensued an interregnum of ten years, during which the country was governed by thirty-six dukes, whose appointment dated from the first days of the invasion of Italy. The dukes now acted as independent sovereigns, and, in order to extend their respective territories, they carried on constant wars with the Greeks and the Franks.

Lombards. and even among themselves. Their government was characterized by great cruelty to the conquered race, whose towns were repeatedly pillaged and burnt. Many of the Roman nobles were put to death to get possession of their wealth, and all the others whose lives were spared were divided among their guests,—*hospites*, as the Longobards insultingly called themselves,—and compelled to pay them one-third of the raw produce of their lands. The Romans at length resolved to avail themselves of the anarchy which the private warfares of the dukes had produced among the Longobards, and, by the aid of the Greeks or the Franks, to try to expel them altogether from the country. Accordingly, Pope Pelagius II. sent a Roman patrician with money to implore succour from Constantinople. The Emperor Mauritius being prevented by his wars with the Arabs and the Persians from attending personally to the application, appointed Smaragdus, a general of great reputation, to replace Longinus at Ravenna, and, at the same time, sent an embassy with a present of 50,000 golden *solidi* to Childebertus, the King of the Franks of Austrasia, requesting him to move against the Longobards. The threatened invasion so alarmed the Longobards, that they re-established the monarchical form of government, and chose Autharis, the son of Clephis, as their king (584–590).

Autharis, considering that the power of the dukes was well established, and that they would not be willing to part with the authority which they had so long enjoyed, allowed them to continue in their government, but obliged them to contribute a moiety of their revenues towards the maintenance and support of his royal dignity. He reserved to himself the supreme dominion and authority, and took an oath from the dukes, that in time of war they would readily assist him to the utmost of their power. Though he could remove them at pleasure, yet he deprived none of them of their dukedoms except in cases of treason, nor gave them to others except when their male issue failed. From an obscure and questionable passage of Paulus Diaconus, it would seem that Autharis also released the Italians from the tribute of one-third of the raw produce of the soil, and caused them instead to give up one-third of their lands to the Longobards, who from that time ceased to be *hospites*, and became settlers in the country. Autharis succeeded in checking theft, murder, and adultery, and was the first Longobard king who embraced Christianity. Most of his subjects followed his example; but, as they were all instructed by Arian bishops, they continued long infected with that heresy, which occasioned great disputes between them and the orthodox bishops of the cities subject to their sway.

Three times did Childebertus descend into Italy in fulfilment of his engagement with the emperor, but he was always repulsed by the young and brave Autharis, who, in his victorious career, is said to have overrun the whole peninsula as far as Reggio, and, planting his halbert in the Sicilian Straits, to have said, that those would be the limits of the Longobard kingdom. The fourth Italian campaign of Childebertus had an origin quite characteristic of the times. He had asked in marriage Theodelinda, a daughter of Garibald, Duke of Bavaria, but afterwards he had changed his mind and refused to marry her. She was then sought and obtained by Autharis, who, in his youthful impatience to see his bride, sent a second embassy, in which he himself went as one of the number. On the embassy being introduced to the presence of the duke, Autharis advanced to the throne and stated that, though not the ambassador, he was the friend of the king, who had trusted him with the delicate commission of giving him a faithful report of the beauty of his bride. Theodelinda being sent for, Autharis, greatly captivated with her charms, after a pause of silent rapture, hailed her as the Queen of the Longobards, and requested that, according to the custom of the nation, she would present a goblet of wine to the

first of her new subjects. The request being granted, Lombards. Theodelinda handed round the goblet. When Autharis' turn arrived, on returning the goblet, he made the fair princess blush by softly pressing her hand, and stealthily bringing it to his lips and forehead. Theodelinda confided to her nurse the indiscreet familiarity of the stranger, and was cheered by the assurance that such boldness could proceed only from the king her husband, who by his beauty and courage appeared worthy of her love. The embassy returned, escorted by Bavarian envoys. No sooner did they reach the Italian frontier than Autharis made himself known to them by raising himself on his horse, darting his battle-axe with incomparable strength and dexterity against a tree, and adding, "Such is the wound that Autharis can inflict." Childebertus, on hearing of the intended marriage, resolved to prevent it, and immediately attacked Bavaria. Theodelinda was obliged to escape for her safety, with her brother Gundobald, to Italy, where she was met near Verona by Autharis, and the marriage celebrated with great solemnity on the 15th May 589. The following year Childebertus invaded Italy with a powerful army; but, after pillaging several towns, and in vain attempting to besiege Pavia, he withdrew without any lasting conquests.

Autharis died the same year, and his youthful widow was allowed to bestow, with her hand, the sceptre of the Longobard kingdom. Her choice fell on Agilulfus, Duke of Turin, 590–615, who concluded a peace with the Franks, reduced several rebellious dukes to obedience, and carried on a successful war with the Greeks. His reign marks an important period in the history of the Longobards and of Italy. Through the influence of Theodelinda, to whom we have several interesting letters from Pope Gregory the Great, he renounced the erroneous tenets of Arius, and joined the Catholic church. His example was eventually followed by his whole nation, whose gradual fusion with the conquered race dates from that time. Many churches had then their property restored; bishops, hitherto persecuted, began to be honoured; numerous monasteries were founded. The palace formerly erected by Theodoric at Monza, near Milan, was restored and enlarged; and adjoining it, the piety of Agilulfus and Theodelinda erected and richly endowed a basilica in honour of St John the Baptist. In this basilica are still preserved three crowns offered by them, one of which, the famous iron crown with which the kings of Italy, and occasionally the emperors, were afterwards crowned, is supposed to be the identical crown placed by Theodelinda on the head of Agilulfus. St Columba, the Irish monk, when he was obliged to escape from Theodoric, King of Burgundy, found a hospitable reception at the court of Pavia, 612 or 613, whence he soon retired to a desert valley of the Apennines, and, under the auspices of Theodelinda, founded the monastery of Bobbio. Both he and his early successors brought together to Bobbio many manuscripts from France and Brittany, which, being scattered among the Vatican, the Ambrosian, and other libraries, at the suppression of that monastery during the late French wars, acquired great celebrity in our times as the *Codices Palimpsesti*, among which Cardinal Mai, then librarian of the Ambrosian, discovered the lost work *De Republica* of Cicero, and other fragments of the ancient writers.

The next two reigns afford nothing remarkable. Adaloald, the son of Agilulfus, who was proclaimed king at the age of twelve, under the regency of Theodelinda (615–625) having gone mad, was dethroned and succeeded by Ariold, Duke of Turin, the husband of his sister Gundeberga (625–636). On a false accusation of infidelity, Ariold threw Gundeberga into prison; but, after having kept her three years in confinement, he consented, at the intercession of her relative, Clotharius, King of the Franks, that her innocence should be tested by a single combat between her accuser and a nobleman who undertook to defend her. The ac-

Lombards. cuser having been slain, she was declared innocent, and released; this was the first instance of a trial by combat in the history of Italy.

On the death of Arioald, Gundeberga was allowed, as it had been previously permitted to her mother Theodelinda, to choose a husband and king. She proposed to Rotharis, Duke of Brescia, who was married, to give up his wife, and take with her hand the Longobard crown. Rotharis (636-652) however, was not more attached to her than he had been to his first wife. Gundeberga was soon shut up in a room of the palace at Pavia, whence she was released after five years at the intercession of the Frank king Clodoveus. Rotharis carried on successful wars with the Greeks of Ravenna, and made himself master of part of their possessions near Venice. He took also and destroyed Genoa, and conquered all the maritime country from the Gulf of Spezia to Nice. But his reign was chiefly remarkable for the introduction of written laws amongst the Longobards, who, before his time, had been governed only by tradition.

He was succeeded by his son Rodoald, who perished after six months by the hand of an assassin, whose wife he had violated. Of the reign of his brother-in-law and successor, Aripertus (652-661), very little is known, except that, at his death, he divided his kingdom between his two sons, Godebertus and Bertharidus, who resided, the former at Pavia, and the latter at Milan. Each brother soon endeavoured to get possession of the whole kingdom. Godebertus applied for support to Grimoald, the powerful Duke of Benevento, who, availing himself of the fraternal dissensions, betook himself to Pavia, where he treacherously slew Godebertus in his own palace, and proclaimed himself King of the Longobards (662-671). Bertharidus fled from Milan, and repaired for safety to the chagan of the Avars.

To give a shadow of right to his usurpation, Grimoald married Godebertus' sister, a granddaughter of Theodelinda, whose memory was still worshipped by the Longobards. He was no sooner seated on his throne, than he was obliged to go to the assistance of Benevento, which had been besieged by the Emperor Constans II., with a large army collected from the various Greek possessions in Southern Italy. After several engagements, Constans was compelled to raise the siege and withdraw to Rome, whence after a few days he departed, carrying with him the brass roof of the Pantheon, and all the ancient bronzes, of which he stripped the old capitol. On his return from Benevento, Grimoald sent an embassy to the chagan of the Avars, asking that Bertharidus should be delivered to him. The chagan refused to give up his guest, but, to avoid a war, expelled him from his country. Bertharidus, aware of the chivalrous disposition of his rival, returned to Italy, and from Lodi, sent his faithful shield-bearer to ask him for hospitality and security. Grimoald generously received him, and assigned him a dwelling and a large pension from the public treasury; but his house was soon frequented by so many noblemen as to excite the suspicion of Grimoald, who was prevailed upon by his courtiers to despatch him. Bertharidus, informed of the plot against his life, sought refuge among the Franks, whom he induced to make a descent into Italy. Grimoald rushed to meet them near Asti, and defeated them (665) by a stratagem. He had encamped himself near the enemy, but suddenly, as if inspired by fear, he raised the camp, leaving behind baggage, food, and a large quantity of wine. The Franks entered and pillaged the deserted camp, and gave themselves up to drinking till past midnight, when they were suddenly fallen upon, and completely routed by Grimoald.

The usurpation of Grimoald was one of the causes of the subsequent anarchy, gradual decay, and final overthrow of the Longobard kingdom. By the great honours and gifts he was obliged to bestow on the dukes who had supported it, he so much raised their power and importance, that, in-

stead of mere delegates of the royal authority, they began Lombards. to consider themselves, and to act as, independent princes; whilst, on the other hand, his success encouraged every one of them to aim at the supreme power. After his death, his son Garibald, a boy, was on the throne a few months, but was easily expelled by Bertharidus, who, on hearing the news of his rival's death, hurried to Italy, and was welcomed by the Longobards as their king. During his long reign (671-688), with the exception of the rebellion of Alachis, Duke of Trent, peace generally prevailed in the country. In 678 he associated with himself on the throne his son Cunibert, whose reign (688-700), after the death of his father, was a constant struggle with the rebellious dukes. One of these, the same Alachis who had revolted against Bertharidus, and been forgiven, was, for a short time, so successful as to drive him from Pavia, and oblige him to take refuge on an island of the Lake of Como, where he fortified himself. But Alachis was finally routed, and slain in a great battle fought near Coronata, and Cunibert remained in the undisputed possession of the kingdom. He left the throne to his son Luitbert, a boy, under the guardianship of Ansprandus, a nobleman of great wisdom and influence; but Ragimbertus, his own cousin, dethroned him, and remained a few months in power. He was succeeded by his son, Aribertus II. (701-712), who seized Luitbert, and had him killed in a bath, and defeating the remnants of his party, compelled Ansprandus to seek safety at the court of Theodebertus, Duke of Bavaria. Ansprandus succeeded, after nine years, in obtaining the support of a Bavarian army, which, swelled by numerous Longobard exiles, enabled him to attack and defeat Aribertus, who was drowned in swimming across the Ticino on his flight to France. Ansprandus survived his victory only three months, and left the throne to his son Luitprand (712-744), who proved by far the greatest of Longobard kings; although his ambition prepared the ruin of the kingdom.

Luitprand was impatient to enlarge his dominions, and for this an opportunity was soon offered by the dissensions which at this time arose between the Greeks and the Romans; the origin of which, however, as well as the events to which they gave rise, are obscurely and differently told by the contemporary chroniclers. The first misunderstanding between Gregory II. and Leo Isauricus, who had ascended the imperial throne in 717, seems to have arisen out of a new tax which the latter imposed on the Italians, and the pope resisted. The emperor, resorting at first to fraud, sent three officers to Rome, with private orders either to despatch the pope, or to convey him prisoner to Constantinople. At the same time, he wrote to Marinus, Duke of Rome, enjoining him to assist his officers in their undertaking. Before they were able to put their design into execution, Marinus died and the whole plot was discovered. Two of the conspirators were apprehended by the Romans and put to death; the third escaped into a monastery, where he took the monastic habit, and ended his days. A new duke was sent from Constantinople, with orders to depose the pope, but he did not even dare to attempt it. Hereupon Paul, the new exarch, who had been sent in 725 to govern Italy, in compliance with the emperor's orders, resolved to proceed no longer by secret plots, but by open force. Accordingly, he drew together a considerable body of troops, and sent them against Rome, with orders to seize the pope and send him in chains to Constantinople. But on this occasion the Duke of Spoleto, and other powerful Longobards, joined the inhabitants of Rome, who, being by this reinforcement far superior in strength and number, met the Greeks near Pons Salaria, and completely routed them.

It was easy to foresee the storm which the news of this defeat would raise at the imperial court against Rome. But a new and more irritating cause came at this time to widen the breach between Greeks and Romans. The Emperor

Lombards. Leo, by his famous edict, forbidding the worship of images, and ordering them to be everywhere pulled down and destroyed, so far incensed his eastern subjects, that, in many places, they openly revolted, and, falling upon the emperor's officers, drove them out of the cities. Leo strictly enjoined his officers in the west, especially the exarch of Ravenna, to see his edict obeyed in their respective governments, and wrote to the pope, promising him his favour if he complied with the edict, and, if he opposed it, declaring him a rebel, and no longer invested with the papal dignity. But Gregory was so far from yielding to the emperor's threats or promises, that, on the contrary, he excommunicated the exarch for attempting to put the edict in execution, and at the same time wrote to the Venetians, to Luitprand, and to the Longobard dukes, exhorting them to continue steadfast in the Catholic faith, and to oppose with all their might such an innovation. Gregory's letters made such an impression on the minds of the people of Italy, that, though of different interests, and often at war with one another, they all united, protesting they would defend the Catholic faith, and the life of the pope, at the expense of their own.

In the meantime, the exarch Paul, having gained a party at Ravenna, began to remove the images out of the churches: a proceeding which incensed the adverse party to such a degree, that, rushing to arms, and falling upon the *Iconoclasts*, or image-breakers, as they styled them, a civil war was raised within the walls of Ravenna. Great numbers were killed on both sides; but those who were for the worship of images having prevailed in the end, a dreadful slaughter was made of the Iconoclasts, and, among the rest, the exarch himself was killed. In Naples, Exhilaratus, duke of that city, in compliance with the imperial orders, did all that lay in his power to persuade the people to receive the edict; but finding his endeavours thwarted by the pope, he hired assassins to murder him. But the plot being discovered, both he and his son were torn to pieces by the Neapolitans, and they shortly after expelled his successor Peter, who had published a libel against the pope.

Leo, hearing of the murder of the exarch, and the general revolt of the cities, and not doubting that the pope was the chief author of so much mischief, sent the eunuch Eutychius to Italy as exarch, strictly enjoining him to have the pope despatched by some means or other. Eutychius went to Naples, and spared no pains to get the pope into his power. He sent a messenger to Rome with an order from the emperor, commanding his officers in that city to put the pope to death without fail. But the messenger being apprehended, and the order found upon him, he was only saved from death by the interposition of the pope himself, who thereupon issued an excommunication against the exarch. Eutychius having brought with him from Constantinople a good number of troops, quelled the rebellion at Ravenna, and severely punished its authors. As for the rebellious Romans, he was well apprised that he could never reduce them, as long as they were supported by the Longobards; and, therefore, he employed all his art and policy to bring Luitprand over to his own interests.

Luitprand, however, far from detaching himself from the Romans, thought that the religious feuds afforded him now a favourable opportunity for extending his dominions at the expense of the Greeks. Having, therefore, drawn together all his forces, he unexpectedly appeared before Ravenna, which he closely besieged. The exarch, who had little expected such a surprise, defended the place with such courage and resolution, that Luitprand, despairing of success, raised the siege, and led his army against Classis, at a small distance from Ravenna, which he took, plundered, and levelled with the ground. The severe treatment which its inhabitants met with from the king, threw the citizens of Ravenna into such consternation, that Luitprand resolved to take advantage of their fear, and returning before the city, by frequent attacks, harassed

the inhabitants to such a degree, that the exarch, finding they could hold out no longer, withdrew privately to Venice. Luitprand, informed of his retreat, attacked the town with more violence than ever, and, having carried it by storm, gave it up to be plundered by his soldiers. The reduction of Ravenna was followed by the surrender of several towns of the exarchate, which Luitprand reduced to a dukedom, appointing Hildebrand, his young nephew, to govern it, and giving him Peredeus, Duke of Vicenza, as his guardian. Among the cities taken by Luitprand at this time, we find Sutri, near Rome, of which the king, at the request of the pope, made a gift to the apostles Peter and Paul: the first instance, often repeated in later years, of restoring to St Peter the cities taken from the empire.

The progress of the Longobards greatly alarmed Gregory II., who, being no less jealous of their power than his predecessors had been, resolved by some means or other to put a stop to their conquests. The only prince in Italy to whom he could have recourse, was Ursus, Duke of Venice. To him, accordingly, he wrote a very pressing letter, conjuring him to assist his worthy son, the exarch, and to attempt with him the recovery of Ravenna. Ursus and the Venetians, moved with the pope's letter, and, at the same time, alarmed at the growth of so powerful a neighbour, promised to assist the exarch with the whole strength of the republic, and fitted out a fleet, pretending that it was designed for the service of the emperor against the Saracens. The exarch, meanwhile, abandoning Venice as it were in despair of bringing Ursus over to his party, raised, in the places still subject to the emperor, what forces he could, and marched with them towards Imola; but turning suddenly towards Ravenna, he laid siege to that city by land, whilst the Venetians invested it by sea. Peredeus defended the town with great courage and resolution; but the Venetians having at length forced open one of the gates on the seaward face, the city was taken, and he himself slain in attempting to drive the enemy from the posts they had seized. Luitprand was then at Pavia; but Ravenna was taken before he could assemble troops to relieve it.

In the meantime, Thrasimund, Duke of Spoleto, who had expelled his father from the dukedom, and forced him to take the habit of a monk, and Romuald, Duke of Benevento, having both revolted, the exarch offered to assist the king with all his means, provided he would in return support him against the pope and the Romans, who had sided with the rebellious dukes. Luitprand readily closed with this proposal, and the two armies joined and marched towards Spoleto. At their approach, the duke, despairing of being able to resist, came out with a small attendance to meet them, and throwing himself at the king's feet, sued for pardon; which Luitprand not only granted, but confirmed him in the dukedom. From Spoleto the two armies marched, in pursuance of the treaty, to Rome, and encamped in the meadows of Nero between the Tiber and the Vatican. Gregory had fortified the city in the best manner he could; but being sensible that the Romans alone could not long hold out against two such armies, taking with him some of the principal inhabitants, he went to wait upon the king in his camp, where he softened Luitprand to such a degree, that throwing himself at his feet, in the presence of the whole army, the king begged pardon for entering into an alliance against him, and assuring him of his protection for the future, he went with them to the church of St Peter, where, disarming himself, he laid his girdle, his sword, and his gauntlet, with his royal mantle, his crown of gold, and cross of silver, on the apostle's sepulchre. After this, he reconciled the pope with the exarch, who was received into the city, where he remained for some time, maintaining a friendly correspondence with the pope.

Gregory did not long survive his success. At his death February 731), his successor, Gregory III., wrote several

Lombards. letters to Leo, soliciting him more pressingly than ever to revoke the edict; and, at the same time, held in the Vatican a council of 93 Italian bishops, who issued an anathema against the *Iconoclasts*. Leo, however, instead of listening to the pope's remonstrances, not only insisted upon his edict being received in Rome, but confiscated all the patrimony which the Roman Church had in Sicily and Calabria. On this the Romans, provoked more than ever against Leo, renounced their allegiance to him, paid him no more tribute, and appointed their own magistrates under the pope, not as their prince but as their head. From these slender beginnings the sovereignty of the popes in Italy took its rise.

At this time Luitprand having fallen dangerously ill, the Longobards chose his nephew, Hildebrand, as his successor; but as the king recovered, Hildebrand remained, in name more than in power, his companion on the throne. Luitprand was soon called upon to put down a new rebellion of the Duke of Spoleto, who was obliged to flee for safety to Rome. Gregory having refused to give him up, the king, before returning to Pavia, took possession of four towns of the Roman territory. Thrasimund, with the aid of the Romans, regained his estates, but did not care to retake and restore to the pope the four towns. Gregory then, finding himself at once betrayed by a faithless ally, and threatened by the warlike and victorious Luitprand, resolved to recur to the protection of the Franks, the only nation capable of coping with the Longobards. They were at this time governed by Charles Martel, who having gained a signal victory over the Saracens in the neighbourhood of Tours (October 732), was generally reputed the best commander of his time. To him, therefore, Gregory sent a solemn embassy, with a great number of relics, earnestly entreating him to take the Romans and the Church under his protection. The ambassadors were received with extraordinary marks of honour, and concluded a treaty by which Charles engaged to march into Italy in person, in defence of the Romans and the Church, if they should be attacked by the Longobards. On the other hand, the Romans were to acknowledge him as their protector, and confer upon him the honour of the consulship, as it had been formerly conferred on Clovis by the Emperor Anastasius, after that prince had defeated the Visigoths.

Luitprand in the mean time marched against Thrasimund, and besieged him at Spoleto; but Gregory did not live to see the fruit of his negotiations. He died in 741, the year in which the Emperor Leo and Charles Martel died, and was succeeded by Zachary, a Greek, who, trusting more to his own means than to the aid of the Franks, gave up the alliance of the faithless duke, and came to terms with Luitprand. Thrasimund, finding all resistance hopeless, surrendered to the king, who compelled him to take the dress of a monk, as he had done to his father. Zachary not only obtained the restoration of the four cities from the king, as well as of a district of the Sabina, which had been seized thirty years before, but in 743 prevailed also upon him to give up his intended attack against Ravenna, and to restore Cesena to the exarch.

At the death of Luitprand, his colleague Hildebrand was left on the throne only seven months, when, being expelled, Rachis, Duke of Friuli, was elected in his place (744-749). During the first years of his reign, Rachis remained at peace with his neighbours, but in the year 749 he invaded the Roman territory, and marched against Perugia. It was whilst he besieged this town, that Zachary, the able and successful negotiator, accompanied by a large number of ecclesiastics and Roman noblemen, went to meet him, and, by vividly painting the punishment that would be hereafter inflicted in the other world on those who violated the rights of the Church, so powerfully operated on his mind, that the king raised the siege, and proceeding to Rome, received from

the pope the tonsure and the habit of a monk, and retired Lombards. to the Benedictine monastery of Monte Cassino. Tasia, his wife, and Ratrude, his daughter, who had accompanied him to Rome, took the habit of nuns, and founded a convent at Piomberuola, in the vicinity of his. Even in our days, the traveller who visits Monte Cassino is shown a spot where the vineyard planted and cultivated by King Rachis is said once to have stood.

Astolphus, his brother, succeeded him on the throne (749-756), and soon showed his warlike and grasping disposition. After making himself master of Ravenna and the *Pentapolis*, as the five allied cities of Rimini, Pesaro, Fano, Sinigaglia, and Ancona, were then called, he marched towards Rome; and, treating it already as a conquered town, demanded a yearly tax of a golden *solidus* from each citizen. Stephen II. who, on the death of Zachary (March 12, 752), had been raised to the papal chair, after vain attempts to appease Astolphus by negotiations, and a fruitless application for aid to Constantine Copronimus, the successor of Leo on the imperial throne, had at last recourse to the assistance of Pepin, the son, and no less wise and powerful successor of Charles Martel. After the preliminary negotiations, whilst a Longobard army was encamped near Rome, Stephen went to Pavia, and having again in vain tried to soften Astolphus, he proceeded to France, and met Pepin at the chateau of Pontyon, on the 6th of June 754. In the spring of the following year, Pepin, accompanied by the pope, crossed the Alps, defeated Astolphus near Susa, and besieging him at Pavia, obliged him to sue for peace. It was granted upon the condition that the exarchate and the towns taken from the Romans should be given up, not to the emperor, but to the pope.

No sooner, however, had Pepin recrossed the Alps than Astolphus, far from fulfilling the terms agreed upon, marched against Rome, laid waste its neighbourhood, and repeatedly stormed the city itself. Stephen had again recourse to Pepin, who descended rapidly by Mount Cenis into Italy, invested Pavia, and, by a vigorous prosecution of the siege, forced Astolphus to add to the restitution of the exarchate and the *Pentapolis*, the surrender of Comacchio. Fulrad, Abbot of St Denis, was despatched to the ceded towns to take hostages, and to receive the keys, which he deposited in the confessional of St Peter's at Rome.

Astolphus died shortly after by a fall from his horse, and Desiderius, Duke of Tuscany, was proclaimed king by the army. Many of the Longobards, however, would not yield him allegiance, and adhered to Rachis, who came out of his monastery with the desire to resume the sceptre. The two rivals were on the point of deciding their contest by arms, when, through the interference of the pope, the monk was prevailed upon to return to Monte Cassino, and Desiderius remained in the undisputed possession of the kingdom (756-774).

At the beginning of his reign, Desiderius tried to establish such a close alliance with the Franks as might further his projects of aggrandizement in Italy, by giving his daughter Ermengarda in marriage to Charles, usually called Charlemagne, the son of Pepin. Pope Stephen III. endeavoured in vain to prevent an alliance which afterwards was to be a source of enmity between the two sovereigns. Charles, in 771, divorced his wife, on the pretext of barrenness, and sent her back to her father, who, in revenge, not only received with hospitality the two sons and the widow of Carleman, but supported their claims to the paternal estates, of which Charlemagne had deprived them. The following year, 772, Desiderius occupied Sinigaglia, Montefeltro, and other Roman towns, and extended his depredations to the gates of Rome. Adrian, who had just been raised to the papal chair, having failed in his efforts to induce the king to leave Rome unmolested, and to restore the places occupied, following the example of his

Lombardy. predecessors, applied at length to Charlemagne. In the autumn of 773, the French monarch marched with a large army across the Mount Cenis to Susa, where he was stopped by the strong line of fortifications, called the *Chiuse d'Italia*, erected by the Longobards. Whilst unsuccessfully endeavouring to force his passage, a deacon from Ravenna, said to have been sent by the pope, showed him a detour, by which he was able to descend into the valley and attack the Longobards on their rear. They, taken by surprise, fled from the enemy with scarcely any resistance. Desiderius sought refuge within the walls of Pavia, and his son Adelchis fled to Verona. The latter place was soon captured, and Adelchis obliged to retire to Constantinople. The defence of Pavia was brave and protracted, but compelled at length by famine and pestilence to surrender (774), Desiderius and his family were made prisoners, and sent to spend the rest of their days in France.

Thus ended the kingdom of the Longobards, who in the course of 206 years had neither been able to complete the conquest of Italy, nor to make the conquered race their friends; had neither preserved their original barbarity, nor adopted the polished manners of the Latin race. It is impossible to know what their language was, though, from those few words that are found with a Latin termination in their laws and in Paulus Diaconus, it may be inferred that it was a dialect of the German, not very different from the ancient Saxon. It would seem, however, that it was never a written language, and that it was soon dropped, even in their national songs, as Paulus Diaconus quotes none of them, though he quotes some in the Saxon and Bavarian languages. Paulus Diaconus, their only national writer, composed his History in Latin after the fall of the monarchy; even their laws were written in Latin, and evidently framed by Latin jurists or clergymen.

It has already been mentioned, that Rotharis was the first king of the Longobards who introduced written laws among them. Grimoald, Luitprand, Rachis, and Astol-

phus, were the other legislators. Their edicts, as they were called, after they had been maturely examined and approved of by the principal lords of the kingdom, were enacted in public assemblies, from which the ecclesiastical order and the people were excluded; so that the legislative power was lodged exclusively in the king and the nobles. These laws, having been respected by Charlemagne, survived for several centuries the fall of the kingdom; and many of them, embodied in the local traditions and statutes of the Italian communes of the middle ages, continued to have their influence till very recent times.

We shall conclude this short historical sketch of the Longobards with the observation, that the two centuries of their power mark the worst period, both for arts and literature, in Italy. The evil genius of destruction was constantly and unsparingly at work. Bad taste, ignorance, and blind superstition, spread all over the country. Even some of the heathen practices, which the Longobards had brought with them from their native forests, when they adopted Christianity, crept into their new religion. Many centuries elapsed before the worshipping of images of vipers, the holding an old walnut-tree as sacred, and such like superstitions, were totally uprooted at Benevento, where Longobard sway lasted the longest. The first glimpses of an improvement and of some learning, though in a monastic form, do not appear till some time after the fall of the Longobard kingdom. Though the later sovereigns, after they had renounced the tenets of Arius, founded many churches and monasteries, yet there are no monuments standing which are supposed to show what really Longobard architecture was in those times; what is sometimes called the *Lombard style*, belongs undoubtedly to a much later period. Of the original Longobard nation scarcely anything remained but their name, preserved in its shortened form of *Lombards*, to the inhabitants of that part of Italy where their principal settlement and the residence of their government had been. (***)

LOMBARDY, OR LOMBARDO-VENETIAN KINGDOM.

THIS beautiful kingdom, comprising one of the richest and most interesting parts of Italy, and forming one of the most valuable provinces of the Austrian Empire, came by degrees and at long intervals into the possession of the House of Austria. The war of the Spanish succession contributed to form its nucleus, and, a century afterwards, the late French wars enlarged it to its present size.

After the battle of Turin, won by the Imperial army under the command of Prince Eugene of Savoy, September 7, 1706, the duchy of Lombardy, which the French occupied in virtue of the Spanish rights, was surrendered to Austria by the treaty of March 13, 1707, between the Emperor Joseph I. and Louis XIV. Thus Spain, after having held it for nearly two centuries, lost it without her concurrence or previous consent to the treaty having been asked. The duchy of Mantua, which its last Duke Ferdinand Gonzaga had allowed the French to occupy during the war, was also given up to Austria by Louis XIV., in order to obtain more favourable terms for himself. After the victories of Napoleon in Italy, these possessions, by the treaty of Campoformio, October 17, 1797, were given up to France, and went to form part of the short-lived Cisalpine republic. Austria received in exchange most of the territories of the Venetian republic, Venice itself included, to which, as a free state, Napoleon had already put an end.

By the final treaty of Vienna of 1815, Austria preserved all the Venetian States; had Lombardy and the duchy of Mantua restored to her; and, to round these possessions, she

received in addition the districts of the Valteline, Bormio, and Chiavenna, formerly part of the Swiss canton of the Grisons, and the Polesine, detached from the papal territory on the left bank of the Po. With the exception of Istria and the other former Venetian possessions beyond the Isonzo, all these states were erected by the treaty into the Lombardo-Venetian kingdom, which is thus a compact territory, bounded on the N. by Switzerland and the Tyrol, on the E. by Illyria and the Adriatic Sea, on the S. by the Papal States and the duchies of Parma and Modena, and on the W. by Piedmont.

A view of the history of the country down to our own times has already been given in this work, under the head of ITALY; and under LOMBARDS will be found a notice of the northern invaders, from whom the name of Lombardy was derived. To avoid repetition, a fuller account of the stirring events from 1846 to 1850 will be given in the article *SARDINIA (Kingdom of)*, with the history of which, during that period, the history of Lombardy is closely connected.

The kingdom extends over an area of nearly 13,208 square miles. Great part of it is a plain, sloping southwards towards the Po and the Adriatic from the main chain of the Alps, which form its northern boundary from the Swiss canton of Lugano to the frontiers of Carinthia. Some of their lower ranges enter the kingdom, and inclose entirely the districts of Valteline, Bormio, and Chiavenna, where their loftiest points are,—the Splügen, 8130; the Legnone, on the Lake of Como, 8120; the Godena, 7549; the Tremezzo,

Lombardy. 5106; and the Corno di Canzo, 4260 feet in height. Some of the mountains on the frontier towards the Tyrol are still higher.

The principal rivers are the Po and the Adige. The former (*Padus, Eridanus*), the largest river in Italy, rises from two springs on the eastern side of Monte Viso, one of the highest summits of the Western Alps, at a height of 6562 feet above the level of the sea, and after a course of more than 380 miles, enters the Adriatic by many mouths. In its progress it receives the waters of numerous tributaries, the principal of which, on its northern side, and within the kingdom, are the Ticino, which takes its rise from several small lakes near the summit of Mount St Gothard, and joins the Po 4 miles below Pavia; and the Adda and the Mincio, the former issuing from the Lake of Como, and the latter from the Lake of Garda. The whole valley of the Po declines towards the E., but in its lower part so gently, that the fall of water in that river, from where it is joined by the Ticino, near Pavia, to its mouth, a direct distance of nearly 180 miles, is not more than about 328 feet. But though languid in its current, in the spring it is generally so much swollen as to cause extensive inundations on both its banks. A more detailed account of this important river will be found under the head Po in this work.

The Adige or Etsch, next to the Po the largest river in Italy, rises in the Rhætian Alps of the German Tyrol, in a small lake near the village of Reschen, and after being increased by the Eisach and other smaller tributaries, it flows by Trent, where it becomes navigable for large boats, and enters the Italian plains above Verona. After a course of more than 200 miles it enters the Adriatic near Chioggia, a few miles N. of the mouth of the Po. The Brenta, the Piave, the Tagliamento and the Isonzo, are all considerable streams, navigable for small boats, and enter the Adriatic N.E. of the Adige.

There are two descriptions of lakes—those of fresh water on the northern frontier at the foot of the Alps, and those of salt water in the flat country on the borders of the Adriatic. The former lakes are of unspeakable advantage, for, never being frozen in winter, they serve the purpose of internal communication, and feed the numerous streams for the irrigation of the lower country. The most remarkable of them, for extent as well as for the picturesque scenery on their banks, are the following:—1st, The Lago Maggiore or di Locarno (*Verbanus*), the most westerly of them. It begins in the Swiss canton of Ticino, and, entering Italy, extends into the boundaries of Lombardy and of Sardinia to Sesto. It is formed by twenty-six brooks, and chiefly by the Ticino, which retains the same name in issuing from the lake till it joins the Po. It is nearly 50 miles long, and varies from 5 to 8 miles in breadth. It is about 640 feet above the level of the sea, and reaches the great depth, according to Jacini, of 2624 feet, or 1984 feet lower than the sea level. In this lake are the BORROMEAN ISLANDS, of which a description has been given in this work. 2d, The Lago di Lugano, which also is partly in the Swiss territory, and is about 24 miles in length, and from 2½ to 6 miles in breadth. It is of great depth, and its surface is 870 feet above the level of the sea. It receives the water of forty-three rivulets, and discharges it partly by the small river Tresa into the Lago Maggiore, and partly by an artificial canal into the small lake of Piano on the E. 3d, The Lago di Como (*Larius*), which is surrounded by lofty, abrupt mountains, that constitute the great romantic beauty of its borders. It has a depth of 1928 feet, is well stocked with fish, and its banks are studded with farms and picturesque villages. Its elevation above the sea is about 650 feet; the length is 27 miles, or 33 if the small Lago di Riva at its northern end be included; and its breadth varies from 1½ to 3½ miles. At Bellagio it divides into two arms, of which the south-western one, ending at

Como, has no outlet; but at the extremity of the south-east-Lombardy. ern arm, near Lecco, it discharges itself by the Adda, which, with 195 smaller streams, has already fed it with water. 4th, The Lago d'Iseo (*Sebinus*), 18 miles long and 5 broad. This lake is 630 feet above the level of the sea, and in some parts has a depth of 985 feet. In its centre there is an island 1½ mile long. It is chiefly supplied by the Borlezza and the Oglio torrents, the latter of which, after passing through the lake, finds the only exit for its waters at Sarnico. 5th, The Lago d'Idro, through which the River Chiese (*Chusius*) passes before it joins the Oglio, is only 7 miles long. 6th, The Lago di Garda, the ancient *Benacus*, the largest and one of the most beautiful of the lakes of Italy. It is nearly 40 miles in length and 10 miles in its greatest breadth. Its surface is 255 feet above the level of the sea, and its greatest ascertained depth is 941 feet. It is chiefly fed by the River Sarta, and the discharge of its waters at Peschiera forms the River Mincio. Being nearly in a straight direction from N.N.E. to S.S.W., the winds from the Alps sweep down it with unbroken violence, and cause most violent storms. It was the subject of the panegyrics of Virgil, of Pliny, and of Catullus, and was rendered celebrated by the victories of Napoleon over Wurmser in the year 1796. 7th, The small lakes of Varese and Pusiano need only be mentioned.

The salt-water lakes and lagoons are formed by the rivers which descend from the Alps, and spread along the shores of the Adriatic; they are defended from the sea by steep artificial walls, not unlike the dykes in Holland, which, in some degree, prevent the influence of the rise and fall of the tides; but in some cases, where the force of the sea has broken through, harbours have been formed. Of such havens, there are four large ones, viz., Malamoco, San Nicolò, Chioggia, and Tre-Porti; and two inconsiderable, viz., Lido Maggiore, and St Erasmo.

There are mineral springs of various degrees of efficacy and reputation for medicinal purposes. The most remarkable of them are at Bormio and Massimo, in the Valteline; at Albano, in the province of Padua; at Caldiero, near Verona; at Recoaro, in the province of Vicenza; at Trescorre and St Pellegrino, in the province of Bergamo; and Cenedo and Piano, in that of Treviso. The climate is mild, except on the border mountains. On the plains the snow scarcely ever remains on the ground, and it is rarely that ice is found in the still lagoons near Venice. What falls from the heavens in winter is much more commonly in the form of rain than of hail or snow. The winter scarcely lasts more than two months; and in February the fields are covered with new grass. In May the hot weather begins, and the harvest is secured in June and July. In September and October the annual labours of the vintage are performed.

The climate, on the whole, is healthy, except in those districts where rice is extensively cultivated, as well as in the vicinity of Mantua, and in the marshy districts extending from the mouth of the Po towards Venice.

The kingdom is divided into two governments or divisions: Venice, which extends from the Isonzo to the Mincio, including all the seashore on the Adriatic to the mouth of the Po: and Milan, which, besides Lombardy proper, includes the former duchy of Mantua, the Grisons districts, &c. Each government is divided into provinces; each province is subdivided into districts; and each district into communes for the administration, and into parishes with regard to ecclesiastical matters. In 1856, with an area of 13,208 square miles, it had 5,503,473 inhabitants, or 416 to the square mile: all of these, with the exception of 7000 Jews, adhering to the Roman Catholic church. Of this population, 2,493,968 belonged to the government of Venice, being, over an area of 6938 square miles, 359 to the mile; whilst the government of Milan, extending over 6270 square miles, had 3,009,505 inhabitants, or 480 to each square

Lombardy mile, the densest population of any European country. In the large towns there are more women than men; but in the small villages the proportion of men is so much greater, that in Lombardy alone there is a surplus male population of nearly 35,000. On an average of sixteen years, there is yearly a marriage in 117, a birth in 23, and a death in 29 inhabitants. Out of 10,000 deaths in Lombardy, 3538 occur, according to Springer, in the first year of life; 1255 occur from 1 to 4; 818 from 4 to 20; 1173 from 20 to 40; 1369 from 40 to 70; 1576 from 70 to 80; 269 from 80 to 100; and 2 beyond 100 years of age. The annexed table shows the divisions into provinces, districts, communes, and parishes, and the respective population of each province:—

The whole country is governed by a viceroy, who is always an imperial archduke, resides at Milan, and receives an allowance of L.6000 a-year; his entire expenses, at the same time, being defrayed by the state. Under him are governors of the two divisions of Milan and Venice. There is a military commander-in-chief, who resides at Verona, and who, with the assistance of a military board, has the direction of the army, and of the several fortresses, with their stores and garrisons. Six regiments of infantry, and two of cavalry, were recruited in the kingdom before 1848; but since that time, the conscription has fallen more heavily, and the contingent has varied in each year. In 1856 it was 6977 for the Lombard, and 5829 for the Venetian provinces, or at the rate of $2\frac{1}{2}$ per 1000 of the population. At Verona is also the supreme senate of the kingdom, which hears the final appeals from the courts of Venice and Milan. Since 1848 there has been no viceroy, and all the viceregal powers were till very lately in the hands of Marshal Radetzky, the commander-in-chief. In February 1857 he retired, and the Archduke Maximilian, a brother of the present emperor, was appointed governor-general.

The chiefs or heads of the ecclesiastical body are,—the Patriarch of Venice, who extends his jurisdiction over the archbishopric of Udine and the suffragan bishoprics of Adria, Ceneda, Chioggia, Concordia, Belluno, Padua, Treviso, Verona, Vicenza, and other sees in Istria and Dalmatia; and the Archbishop of Milan, who is the metropolitan of the episcopal sees of Bergamo, Brescia, Como, Crema, Cremona, Lodi, Mantua, and Pavia.

The government is an unlimited monarchy. The law of Lombardy, April 15, 1815, called into existence provincial assemblies (*congregazioni provinciali*) of deputies, selected by the government out of three names given for each deputy by the communes; and created, likewise, central assemblies (*congregazioni centrali*) for the two divisions of Milan and Venice, of representatives named directly by the government. But the functions of these congregations are merely to represent to the sovereign the wishes and wants of the people, and to suggest such measures as may be conducive to the welfare of the country. They do not in any way extend to the voting or altering of the taxes, to the framing of the laws, or even to the prevention or suspension of the operation of such laws as may be promulgated by the central authority at Vienna, or by the local viceroy. The resolutions and observations of the provincial congregations are to be submitted to the central congregations, and, if approved of, transmitted by them to the viceroy or governor-general. They have no means of direct communication with the imperial government at Vienna. According to the law, there is no fixed time for the meeting of these congregations; but the viceroy, or governor-general, after previously obtaining the permission from the aulic council at Vienna, may summon them whenever it is deemed advisable. The central congregations were never summoned till 1845; after the insurrection of 1848, they were, for the first time, recalled into existence in July 1855. Their attributions were defined by an imperial ordinance of November 3, 1856; but they were not assembled till the end of January 1857. The provincial congregations have been summoned oftener; but their suggestions and representations have remained useless for the want of the central congregations, which are their legal organ of communication with the government.

The communal or municipal representation given to Lombardy, by the edict of December 1755, which had been abrogated under the French government, was recalled into existence, and applied to the whole kingdom, in 1816. All landholders, who are neither under age, nor soldiers, nor curates, nor debtors of their respective communes, including the legal representatives of women and minors, meet twice a-year in a general assembly (*convocato*), to discuss the budget of the coming year (the *presuntivo*), and to approve of the expenses of the past year (the *consuntivo*); to appoint teachers, doctors, surgeons, and midwives; to decide upon roads, works of public utility, assistance to the poor, and to vote the taxes required for carrying them out. They also name a triennial committee of three of their members, who, after their nomination has been approved by the government, administer gratuitously the communal property, carry out the resolutions of the *convocato*, make the first investigation about crimes, and have the supposed criminals arrested by the *gendarmes*, &c. Each *convocato* is presided over by a commissary, who ought to confine himself to record the resolutions of the meeting, and prevent their overstepping their attributions, without giving any vote himself, or influencing public opinion in any way. A part of the law scarcely, if at all, attended to of late years. All communes that have more than 300 landholders, to avoid too numerous a meeting, appoint a triennial council of thirty members, to whom all municipal attributions are delegated.

The revenue of the kingdom is derived from direct and indirect taxes, and in some degree from national domains, part of which once belonged to the Church. The most important tax is the territorial impost, an ancient payment, which has been alike collected under the several rulers who have at different times administered the finances of the country. In order to equalize its rate according to the productive powers of the soil, the Emperor Charles VI., in 1718, named a commission to form a *catasto*, or general

Lombardy. registry, in which the extent and value of all lands and buildings that were capable of giving any income, however small, should be duly entered. Its execution was impeded many years by the opposition of privileged classes, and by the war of 1733; but it was resumed in 1749, and finished in 1760, when it came into force. The value of property was set down in *scudi* (about 3s. 7d.), and the assessment was in cents (*centesimi*) of *lire* ($\frac{2}{3}$ ths of 1d.) on each *scudo*. Not many years elapsed, however, before it was found that the valuation in some instances fell short of, and in others exceeded, the real income; and that, therefore, the taxes weighed in a very unequal degree upon different estates. At length, in 1822, with a view to rectify the valuation, and equalize the impost, a new general *cadaster* for the whole kingdom was begun; but the commissioners appointed to do it have proceeded so slowly, that as yet it is completed only for the Venetian, and for a few of the Lombard provinces. The new cadaster registers, not the capital value of property, as in the old one, but the supposed net yearly income in Austrian lire, and rates the corresponding tax in cents of lire.

This tax, which before 1802 was only 11 centesimi (9 for public, and 2 for municipal burdens), had increased in 1847 to about 24, and in 1851 it reached at least 34 centesimi for each *scudo* of valuation. The 11 cents paid at the beginning of the century were then reckoned to represent about 22 per cent of the net income: in the same proportion, the present tax of 34 cents would absorb nearly 70 per cent. of the net income. But the production of the soil has so much increased during these fifty years, that, according to Signor Jacini's account, in his interesting work, lately published, on landed property in Lombardy (*La Proprietà Fondiaria e le Popolazioni Agricole in Lombardia*), those 34 cents represent on an average only 32 per cent. of the net income, though numerous instances occur in which they represent 50, and even 60 per cent. Such is the case with the *marcite*, or winter meadows, the produce of which has scarcely increased from what it was already in the last century; and with lands derived from mortmains, which, in compliance with the spirit prevailing at the time, were greatly overcharged at the original formation of the cadaster. In several districts, however (as the Polesine, part of the provinces of Brescia and Milan, &c.), military rates, local municipal taxes for roads, drainage, &c., are so much higher than those above stated, that taxes of one kind or another are said to absorb from 60 to 70 per cent. of the actual income.

With these exceptions, all public burdens on the landed property in the kingdom, for the present year 1857, may be stated to amount to 36 per cent. of its net revenue, of which nearly 23½ per cent. forms the direct government tax. About 6½ per cent. is for local taxes, collected and employed by the municipal authorities; 2 per cent. for extra taxes, to meet military expenses of 1848 and 1849; and the remaining 4 per cent. is absorbed by the tax on the transfer of property, introduced by the law of February 1850, by the forced loan of the same year, &c. As this impost is collected from the proprietor, it is regularly paid, and attended with little cost in the collection.

The whole produce of the direct government tax on land in 1856 was, in round numbers, for Lombardy, L.950,000, and for the Venetian provinces, L.676,666—total, L.1,626,666; being for Lombardy alone above L.465,006 more than what it was before 1849.

Previous to 1846, the kingdom had to transmit to the imperial treasury at Vienna a net yearly sum of L.1,066,666, in two half-yearly remittances. Neither the gross sum of the revenue at present produced by the kingdom, nor the clear amount that reaches the imperial treasury, are known; but an idea of them may be gathered from the fact, that the gross sum of direct and indirect taxes for the govern-

ment of Lombardy alone, in 1855 and 1856, averaged Lombardy. from L.2,833,333 to L.2,933,333.

By comparing these items with the gross revenue of the Austrian empire, which, in 1855, according to the official returns, was L.26,378,688, of which L.6,074,812 were derived exclusively from the direct land tax, the following interesting results may be gathered. The Lombardo-Venetian kingdom, which is nearly one-fifteenth in area, and little more than one-seventh in population, contributes not much less than one-fourth of the whole direct land tax revenue of the empire; and Lombardy alone, which, compared to the whole Austrian empire, has less than one-thirtieth of its extent, and one-thirteenth of its population, contributes more than one-ninth of the whole gross revenue of the empire. The results will be equally remarkable if their respective agricultural wealth is compared. The official returns of 1850, whilst giving L.129,846,800 as the whole gross agricultural produce of the empire, stated that of Lombardy as L.12,021,000, or less than one-tenth; yet the landed property in Lombardy pays about one-sixth of the direct revenue derived from the whole landed property of the empire.

Lombardy extends over about 5,292,447 English acres, of which 340,277 acres are lakes, rivers, and barren rocks, which, yielding no produce, are not included in the general cadaster. The remaining 4,952,170 acres are all surveyed lands, of which a little more than one-half, or 2,799,224 acres, are regularly cultivated, and the other 2,152,946 acres consist of woods, indifferent mountain pastures, marshy tracts, building land, or poor land, yielding scarcely any produce. The net income from all the surveyed land being, according to Jacini, more than L.4,300,000, gives an average return of about 17s. 4d. for each English acre. But as that landed property is encumbered with L.17,566,666 of mortgages, producing L.790,500 of interest at the average rate of 4½ per cent., it follows that, after deducting that interest, and the L.1,500,000 of government and municipal taxes, the net income that remains to the Lombard proprietors from their lands will be reduced to L.2,009,500, which, capitalized at 3½ per cent., the usual rate at which land is valued in the country, gives L.57,414,285 as the net value of the landed property of Lombardy. Though there are many large estates, yet most of this property is much divided, and its subdivisions increase every year. The number of landholders, which in 1838 was 385,826, in 1850 had increased to 437,725. But as many of those who hold property in various districts reappear several times in the returns, it is estimated that the land is actually distributed among 350,000 different owners; of whom about 3000 belong to the class of noblemen, and own, in the aggregate, less than one-fifteenth of the soil. There is therefore a landholder for every 8 inhabitants, for every 15½ acres of the whole area, or for every 8 acres of the cultivated land of Lombardy.

For the Venetian provinces there are no such detailed statistics. Their *surveyed* lands, capable of yielding a return however small, extend over 4,511,506 acres, of which 54,899 acres are exclusively devoted to vineyards. Nearly one-half of the whole extent, or 2,213,400 acres are arable lands, in many of which mulberry or olive trees, and vines, are scattered among the corn fields.

The following table shows the whole rateable income from lands and buildings in the Venetian provinces, as well as the comparative wealth of each province:—

Provinces.	Income.	Provinces.	Income.
Venice.....	L.203,597	Belluno	L.49,229
Padua.....	296,676	Vicenza	317,661
Rovigo.....	151,112	Friuli.....	212,663
Verona.....	298,356		
Treviso.....	210,481	Total.....	L.1,739,775

Lombardy. The quantity of cultivated lands in Lombardy, and their relation to the whole area in each province, as well as the mortgages that encumber them, and their net value, will be seen from the annexed table:—

Provinces.	Lands regularly cultivated.			Total extent of surveyed and unsurveyed lands.	Value of surveyed lands and buildings.	Average value of each acre cultivated or built upon.	Amount of mortgages.	Net value of the property.	Ratio of the mortgages to the value of the property.
	Irrigated.	Not irrigated.	Total.

In few parts of Italy is education so general as in the Lombardo-Venetian kingdom. In Lombardy alone, in 1854, there were 5488 public and private institutions for elementary education,—2822 for men, and 2666 for women. In the same year, the children of an age to go to school were 192,545 boys, and 191,224 girls; and those who actually went were 146,907 boys and 128,199 girls. The largest attendance was in the province of Bergamo, where, out of 57,010 children, 50,734 went to school; and the worst in the province of Mantua, in which, out of 33,895 children, only 16,445 frequented schools. For the higher branches of education there are lyceums at Bergamo, Brescia, Como, Cremona, Mantua, Vicenza, Treviso and Udine; seminaries attached to every episcopal see; the universities of Pavia and Padua; medical and surgical colleges at Milan; several scientific and literary institutions, &c. In 1855 there were 12 newspapers and 47 scientific and literary journals and reviews published in the kingdom. Of the 6874 works published in the Austrian empire in 1853, 1444 were published in Lombardy, and 1194 in the Venetian territory; total 2638,—of which 128 in folio, 621 in 4to, &c.; 2550 of them were in Italian, 50 in Latin, 8 in French, 7 in Greek, 4 in English, 4 in Armenian, 4 in German, and 11 in other languages. The largest items were—

	In Lombardy.	In the Venetian.

In Lombardy, in every 26 births, there is one illegitimate child; the proportion is about the same in the Venetian provinces. Yet the state of public morality, especially among the numerous agricultural classes living scattered in towns and villages, is much better than what that number would represent, as many legitimate children, secretly left at the foundling hospitals by parents utterly destitute of means to rear them up, are calculated as illegitimate. They are often the unfortunate offspring of marriages entered into too hastily, and without means, by very young men, in the hope of evading the law of conscription.

The poor find some relief in their want and illness from numerous hospitals, houses of refuge, charitable institutions, &c. The aggregate income of all these establishments in Lombardy in 1844 was L.427,022, of which L.149,980 being absorbed by burdens and expenses of administration, there remained L.286,797 a-year for charitable purposes. Their revenue has increased considerably since that time. There are besides 27 *Monti di Pietà*, or public pawning-houses lending money at a very low interest. Their total circulation is nearly L.100,000 a-year, for which they receive about 300,000 articles in pawn.

Great convenience is also afforded to the poorer classes by savings-banks, the first of which was opened at Milan in 1823. At present there are 14 in Lombardy, all under the management of a central committee. They receive deposits of from 1 to 300 lire (from 8d. to L.10), on which they pay an interest of 3½ per cent. From the 1st July 1823 to the 31st December 1855, they had issued 169,989 account-books, and had received 1,108,598 deposits for L.4,967,510, on which L.479,697 of interest had accumulated; they had made 526,439 reimbursements to the amount of L.3,715,756. On the 1st of January 1856 they had a balance of L.1,731,450 deposited by 66,134 different persons, giving an average of L.26 for each person. On the 30th December of the same year the amount deposited had increased to L.1,897,562. In the government of Venice it is only within these few years that savings-banks have been introduced; but their operations as yet are not very considerable. On the 31st December 1854, they held a balance of L.62,998, deposited by 1837 persons, each at an average amount of L.34, 5s. 4d.

The whole kingdom may be divided into three distinct regions:—

1. The *Mountain Region*, which comprises the whole province of Sondrio, the greater part of the provinces of Como, Bergamo, and Belluno, more than two-fifths of the province of Brescia, and some districts of the provinces of Udine and Vicenza; altogether about one-third of the kingdom. It is the region where property is mostly subdivided. Its trees are chiefly fir, larch, birch, oak, and chestnut. There are summer pastures in the mountain slopes and valleys. The vine, the mulberry, and common fruit trees, are grown on its southern declivities, which are cultivated with great care and labour; the ground is formed in terraces, which are sometimes supplied with earth from some distance to replace what is washed away by the heavy rains.

2. The *Hilly or Sub-Alpine Region and Upper Flat Country*.—It embraces the southern part of the provinces of Como and Belluno; the northern part of the provinces of Milan, Mantua, Verona, Vicenza, Treviso, and Udine; and the central districts of the provinces of Bergamo and Brescia. Its chief productions are,—silk of the finest description, wine, maize, millet, chestnuts, fruit, and vegetables. Even lemons are grown on the southern shore of the lake

Lombardy. of Garda. It is the region which contains most of the manufactures of the kingdom.

3. The *Low Flat Country*, which comprises the southern part of the provinces of Brescia, Bergamo, Milan, Mantua, Padua, Treviso, and Udine; and the whole provinces of Pavia, Lodi, Cremona, Rovigo, and Venice, including the marshy lands and extensive lagoons all along the shore of the Adriatic. It is the region of irrigation and of *malaria*. In many of its districts, sickness is marked in the complexion of the inhabitants, and numbers of Tyrolese and Illyrian peasants who descend from their mountains to gather the harvest, fall victims to the marsh fevers. The whole central part of the basin of the Po, on its left bank, is within this region. Its chief productions are,—the Parmesan cheese, rice, silk, wine, maize, flax. Property is less subdivided than in the two other regions.

As Lombardy is the most densely peopled, so it is the best cultivated district in Europe. Its wealth and prosperity being derived chiefly from the productions of the soil, an extended view of its agriculture must be of much importance; and we enter upon the subject here, because in the description of the agriculture of the other parts of Italy, it will only be necessary, in the progress of this work, to refer generally to the practices of Lombardy, and to point out the few differences that may exist.

The importance of irrigation is more felt, and the practice of it more extended, in Lombardy, than in any other part of Europe. This depends much on the physical features of the country, which, as it has been stated, forms in great part a gentle slope from the foot of the mountains, where are those large reservoirs of water already described, to the bed of the Po, into which finally empty themselves the numerous streams that, issuing from the lakes, serve the double purpose of internal navigation and of irrigation.

The facilities for irrigation in the best districts have been much increased by the construction of canals, which, whilst they serve the purpose of inland navigation, are made use of to convey streams of water over the fields, which pass from the property of one proprietor to that of another, till they again enter the canals at a lower level. Some of these canals are the work of remote ages. The most ancient, as well as the most considerable of these, is the *Naviglio Grande*, which was opened in the year 1270.

An ancient law of Lombardy has contributed, from the most remote period, to the extension of the distribution of water. The whole of that substance was the property of the sovereign. An individual, or a corporate body, might purchase the water, and thereby acquire the right to conduct it by canals in any direction, and there to sell it to the cultivators. But they could not carry it through gardens or pleasure-grounds, and were bound to pay the owners of the land the value of that portion which was made use of for the passage of the water. In process of time the right of the sovereign over the water was ceded to those who became the purchasers thereof, and was at length extended to those who had springs on their ground, or should afterwards discover any.

The value of water in Lombardy is best seen by a comparison of the rent paid for land of the same quality, according to the power of obtaining irrigation. Dry meadows will let at from 24s. to 40s. per English acre, and that so situated as to be accessible to water is eagerly rented at from 48s. to 160s. per acre, according to its greater or less capability of obtaining water.

The purchase and sale of water is a traffic of much importance in Lombardy. There are individuals whose sole but respectable incomes are derived from such operations.

The distribution of water is settled for a term, with strict covenants between the parties. Fixed days and hours are appointed for opening and shutting the sluices, and watchful guards are appointed; but, in spite of all precautions,

the courts of law are supplied with most abundant processes from the several parties. The volume of water is reckoned by means of a local measure called the *oncia*, being about two English inches. A mechanical contrivance, invented by Ferrari, has for a number of years been applied to the measuring of water, and has been found to be accurate in its operation.

The value of water depends upon a variety of circumstances, and the purchaser can afford to pay more for that which is applied to gardens and to meadows than for what is wanted on arable land. The water of the canals is of more value than that which comes immediately from springs or from small brooks. That water which has passed over the land is worth more than that immediately from the canals, as it is supposed to bring with it more nutritive particles. In the vicinity of Milan the water of the Vettabbia is more valued than any other, because it contains particles of matter collected from the filth of the city. In that neighbourhood, the common water obtained from the other canals is generally, where a constant stream is bought, paid for at the rate of from L.40 to L.50 the *oncia*. If it be bought for the winter only, the payment is not more than the same number of shillings. Some instances are stated by a writer of accuracy and veracity, where an *oncia* of water has been sold for more than L.600. (Breislak, *Descrizione Geologica della Provincia di Milano*.) See IRRIGATION and HYDRODYNAMICS.

Whatever may have been the original component parts of the soil of Lombardy, yet from the great facilities for irrigation, those lands which are susceptible of that operation have become the most productive of any in the kingdom, or perhaps of any in Europe. There are, however, some exceptions; they are indeed but few, and chiefly confined to the vicinity of Mantua, where, even with great power of watering, the land, which is mere sand, does not produce copiously.

These watered lands may be divided into three classes: The first of them, "convertible meadows," or, in Italian, *Prati a Vicenda*, are the most abundant, and are constantly increasing. They are prepared to be laid down in grass by previous corn or green crops, and those are preferred which require good manuring, and also best tend to clean the land from weeds. The course adopted, therefore, is to grow maize and then wheat, or to sow hemp, succeeded by millet, and that followed by wheat; or, in the first year, to sow hemp and then millet, in the second year maize, and in the third wheat. In each of these rotations a half fallow is introduced, and the ground three or four times ploughed, and such fallowing is either in the spring or the autumn, as may best suit the variations in the rotation. Red clover is generally sown in the wheat, which yields a good crop the first year after the wheat harvest, which usually takes place in June, and in the following spring; but after that it disappears, and gives place to most abundant crops of white clover. It continues in grass for three, or in some cases four years, during which time it is mowed three, four, and even five times in the course of the summer. During the process of fallowing, great pains are taken to remove any such inequalities of the surface as would impede the equal distribution of the water over the whole of the field. The soil is removed by a machine contrived for that purpose, from any part above the level of the field, and thrown into the hollows. The field is divided into narrow beds, between each of which is a water-furrow. In the process of watering, these become first filled, and then from them the water is let in till it rises sufficiently high to cover the whole surface of the land. The same furrows, in excessively rainy weather, serve to drain the land of its surplus moisture. The mode of ploughing naturally raises the middle of the bed somewhat higher than the sides of it, but the difference seldom ex-

Lombardy ceeds four or five inches. The application of fields of this description may be generally stated to be as follows: Three-sixths grass, one-sixth wheat, one-sixth maiz, and the remainder flax, beet, rape, or other green crops. There are, as must be obvious to any one acquainted with agriculture, many variations; but, assuming the crops to be grown in that proportion, we cannot be far from accuracy. The portion of the grass land on these meadows is very great; in many instances, where there have been but three mowings and subsequent feedings, they have yielded six London loads of hay to the acre on the average of years, and in some of the best farms near Lodi, a load more. There may be mentioned amongst the convertible meadows, those which are chiefly cultivated with rice, which are on the lowest level, and where the watering is the rule, and the letting them dry the exception. The water on them is stagnant during the greater part of the growth of the crops; but, to change the rotation, it is in some years cultivated along with other plants. Such lands may be generally stated to yield, one-half of them rice, and the other half an equal portion of clover, wheat, and maiz.

The second of the classes of watered lands are those denominated "permanent summer meadows" (*Prati stabili estivi*). These are, day by day, diminishing in extent, as the cultivators become convinced that it is more profitable to change the plants for a few years, than to leave them constantly in grass. The difference in produce between these and convertible meadows arises chiefly from the gradual disappearance of the clovers, and their place being occupied by a variety of the common grasses. They are fitted more for having their plants converted into hay than those of the convertible meadows, and less adapted for the growth of those kinds of grass which are, in conformity with the general practice of the country, most beneficial for stall-feeding. After the last mowing, they are depastured by the oxen.

The most important portion of the land in Lombardy is that part designated as "permanent meadows" (*Marcite*). In laying them down, great attention is paid to levelling the surface, so that no inequalities may prevent the regular distribution of the water in passing over them, and that in no part there may be hollow places in which it can become stagnant. They can only be created in situations where a flowing stream can in all seasons at pleasure be turned over them. They are usually laid down by sowing them with *Lolium perenne*, or rye-grass, with about one part of red clover; and the sweepings of the hay loft are abundantly scattered. As these meadows grow older, other grasses appear; and in the latter mowing of each year, a large portion of white clover is always found. These meadows are well dunged every year, and the omission of it, even once, is considered by good cultivators as an unpardonable fault. Thus, if the other descriptions of land are not manured, it is because all of them are sacrificed to the winter meadows. Everywhere are to be seen on them heaps of manure, which are to be prepared during the summer, in

order to be carried out and equally spread over the surface in the autumn. Those who intend to mow their meadows in the middle of December, carry the manure on them in the latter end of September, and then begin watering them; but those who design to mow them in January carry on the manure at the end of October, or till the middle of November. If sufficient manure be not obtained from the farm, either ground rape-cake or ashes are used abundantly for the purpose, and thickly scattered over the soil.

The manure is separated as much as possible before the watering commences. At first the water is turned over the meadows in very small quantity, that it may produce the solution of the manure, and thus sink it down to the roots of the plants before the force of the stream can carry it away. Afterwards the water is let on in greater quantities, and especially when the temperature of the air is below the freezing point. At such times the greatest attention is given to create such a current of water as shall prevent it from freezing. If the cold is sufficiently strong to form a thin coat of ice, which rarely happens, the water is instantly withheld, and thus the soil remains free from frost, whilst a thin sheet of ice covers it; and if the cold, as usual, is but for a few days, an additional stream of warmer water melts the ice or carries it away, and the grass remains uninjured, and continues to grow. If, however, the frost should be so strong as to freeze the ground, the first mowing of the meadow would be lost; but such occurrences are so very rare, that they are looked at without apprehension, by the cultivators.

As the chief profit as well as the receipt of ready money to the cultivator depends upon the cheese he makes, it becomes of great importance to him to have an abundant supply of green food to produce the milk; and this, which to the farmer is afforded in the N. of Europe by the use of turnips, mangel-wurzel, or meal in tepid water, is supplied in Lombardy, during ten or eleven months, by his winter meadows. It is hence not a subject of surprise that every other portion of his land is sacrificed by the Lombard farmer to the necessity of raising the product of his winter permanent meadows to the highest possible state of productiveness.

As the lands here spoken of are continually in a state of producing crops, they would in time become exhausted in spite of the irrigation, if they were suffered to remain without the application of abundant manure. Although some considerable quantity of extraneous manure is to be procured from the large cities, by those cultivators who carry on their operations near them, or the canals connected with them, yet the larger portion is provided for by the live stock which is maintained on the land. The chief labour of ploughing, except in a part of Pavia, is performed by oxen, and horses are used for the carts and waggons only. The cows are kept in the best possible condition, in order to enable them to yield milk in the greatest quantity, and of the richest quality. The number of black cattle is considerable, as will appear from the following official account of what existed in 1852:—

Provinces.	Oxen.	Cows.	Bulls.	Young Cattle.	Total.	Rams.	Sheep.	Lambs.	Goats.	Total.	Pigs.

Lombardy. The whole of these animals are constantly fed in their stalls, or, if sent out to graze, it is but for a very short period. The use of roots, such as turnips, ruta бага, and mangel-wurzel, is almost unnecessary, as the cattle can be supplied with sufficient green food from the meadows the whole of the year. The farms where the convertible husbandry is followed have abundance of litter from the straw of the wheat, but especially from the leaves of the Indian corn, which, though good food whilst they are green, are, when they become dry, used in the cattle-stalls for their bedding. Whilst this practice of stall-feeding has been found by long experience the most favourable to the health of the cattle, it is decidedly preferable on account of the vastly greater quantity of manure which it produces. On all the meadow farms a great number of pigs are fattened on whey mixed with the flour of Indian corn. These are put into the sties when they have attained the weight of 100 or 110 pounds, and are kept there during five or six months, till they attain the weight of 350 or 360 pounds. It is found that twenty such pigs yield ample manure for four or four and a half acres of the meadow-land. This kind of manure is highly esteemed for that purpose, but more especially so when proper reservoirs are constructed, out of the influence of the sun or the rain, for the preservation of the urine of the animals. In Lombardy are many small occupiers of land, who have not a number of cows sufficient to yield as much milk as will make a cheese daily. These sell their milk to the cheese-makers near them. In their agreement for the milk for the year, the purchaser contracts to keep in the seller's sties a number of fattening pigs, determined upon by calculation of the quantity of milk which the cows will yield. The number of swine fattened by the meadow occupiers, which in 1852 amounted to 119,943, was reduced in 1854 to 106,839; their flesh is in part made into hams, bacon, and especially sausages.

In a country where the land is chiefly ploughed with oxen, and where, as in Lombardy, much work is performed with the spade and the hoe, the number of other beasts for draught will be proportionally inconsiderable. This is the case here, as the following official account shows, as far as relates to the government of Milan:—

Account of the number of Draught Cattle in 1852 and 1854.

Provinces.	Horses.	Mules.	Asses.
Milan	10,519	1,907	2,233
Bergamo	7,096	2,227	2,982

Sondrio	1,413	462	604
Cremona	11,764	878	812
Total	68,550	12,210	15,141
Do. in 1854.....	68,738	12,054	15,557

So scanty a stock of this description of animals can yield but little manure, how carefully soever it may be preserved; nor, with the addition made to it by the 186,390 sheep and goats that are kept, will it bear any comparison with that arising from the 449,150 head of black cattle.

It deserves notice, with reference to this subject, that the rural parts of Lombardy exhibit but few houses except those of the mere peasantry. The proprietors of even the smaller properties, though they may in some measure be viewed in the light of cultivators, yet, placing their estates in other hands, on the system of the *mezzeria*, seldom find it necessary to reside on or near them, and are satisfied with visiting them at the seasons when the produce is to be

divided. When the estates are of small or of moderate extent, Lombardy, or when they are large and comprehend several farms, the superintendence is intrusted to their agents. Such agents, also, in some cases, have the disposal of the share of produce, and account for the proceeds to the proprietors of the soil.

The great body of the population who are in circumstances of even moderate ease are thus collected in the cities and large towns; and in them is thus also collected that mass of corrupted vegetable and animal substances which is most adapted to the purposes of manure, and which is carefully preserved for that application. The cities and towns thus contain a larger proportion of the whole inhabitants than most of the other parts of Europe. If the numerical portion is not greater, the portion who, by their mode of living, produce the greatest quantities of exuviae, which are convertible into manure, is much larger. Such of these substances as are of the liquid kind, or are the most easily reduced to that form by putrefaction, are carried into the canals and rivers on which the cities and towns are built; and, when their water is distributed over the first fields with a gentle motion, to enrich them by the deposition of the matter they contain in suspension, no other manure is required to be applied. Whilst the lower grounds near the cities are refreshed by these means, the higher grounds are supplied, with little expense of labour in the conveyance, from the substances which retain a solid or less soluble form.

With the best farmers it is the custom every year to clean out the small canals of irrigation that are formed in every part of the meadow-lands. These ditches contain a compost of various earths, with a large quantity of vegetable and animal matter produced by the decomposition of many organic substances. It is obvious that each of these canals becomes a reservoir, in which is deposited the matter which the water has brought, and which being mixed with the earth in them, must have a great degree of activity in promoting vegetation.

In some lands of an inferior quality, the practice of growing green crops, and ploughing them in to form manure, has been introduced. A kind of bean called *fisole*, a species of lupin, grows almost spontaneously on some of even the poor soils. When they are cultivated, they produce a large quantity of succulent vegetable matter, which, when covered with earth, and mingled with it, forms an excellent pabulum for other plants. By two operations of this kind in succession, some of the poorest soils on the hills of moderate height have been sufficiently enriched to bear profitable crops of wheat. There is a part of Lombardy, not inconsiderable, where very little or no manure is applied to the land, and yet it is cultivated with corn, though the crops grown are very scanty. It is a portion of the delegation of Mantua, and not far from that city. It is easily susceptible of irrigation, but the soil is one of the poorest descriptions of sand. It is chiefly cultivated by small occupiers. These tenants have no cattle of any kind, and the whole labour is performed by the sole use of the spade and the hoe. Their dwellings and their clothing are of the most wretched description; their food of the coarsest kind, and of that they have at times a bare sufficiency. Their usual course of cropping is alternately with Indian corn and wheat. The farms are from four to eight acres in extent, and are divided into two equal parts, growing the two kinds of corn. One-half of the produce is delivered to the proprietor, out of which he pays the taxes, and the other is for the subsistence of the occupier. In some cases the owner takes that half which consists of wheat, and the tenant is supported on the Indian corn. The value of these is nearly equal, as the price of wheat is commonly about one-third higher than that of maize, whilst the quantity of the latter exceeds that of the

Lombardy. former in about the same proportion. As the maize is nearly three months in the earth, and the wheat scarcely more than six months, there is an interval between the crops, during which the soil, by being frequently turned over by the spade, imbibes a certain portion of oxygen, which, with the addition of water by the irrigation, furnishes food for the plants.

A district adjoining to this, with a soil somewhat less sterile, but capable of constant irrigation, is chiefly cultivated with rice, growing almost continually, or with very short intervals, in the water. The inhabitants are scarcely maintained on better or more abundant provisions; and, on account of the maladies produced by the stagnant water, are remarkable for their sickly appearance, and for the short duration of their lives.

Lombardy comprehends a large portion of the Alps within its limits. The elevated pasture lands on these mountains are stocked with cattle only during the summer months. At that time the peasants take up their temporary residence in the chalets, and there convert the milk of the cattle into butter and cheese, as is practised in the adjoining Swiss cantons. The dung of the cattle serves to refresh the pastures during the summer, but no extraneous manure is ever applied to them.

Some mineral manures are used, the most important of which is gypsum, which is ground in mills, and then scattered on the clovers and the grass. Lime is used as a manure in some of the provinces. It is laid on the ground in heaps in October, and covered with the soil; and after the sowing of wheat, the compost with the lime, completely slaked, is spread over the field. The quantity of lime is very small.

In taking a view of the amount of the produce of land in Lombardy, it may be best to begin with the estimate of the *marcite*, or winter-watered meadows. These are commonly mowed four, five, and even six times in the year; but it is not very easy to determine the quantity of hay they yield, because the chief portion of their produce is consumed by the cattle in the stalls, in the form of grass. One of the most accurate of the practical cultivators (Berra) constructed a weighing-bridge at his farm, over which every load of grass brought from his meadows, as well as the manure carried on them, was weighed and registered. According to him, the average produce, for a series of years, was as follows, in English cwt., and English statute acres:—

	lb.
1st mowing in January.....	11,160
2d ... March.....	16,512
3d ... May.....	17,220
4th ... July.....	9,664
5th ... September.....	8,244
	<hr/> 62,800

That is, 560 $\frac{1}{4}$ cwt., or 30 loads.

The whole of the grass which is cut in January and in September is eaten in the green state, and the hay is made almost exclusively from what is cut in May and July. In what is converted into hay, it is found that there is a loss of weight by drying, equal to three-fourths. It is supposed that, from its containing so much more water, the grass cut in January and September would lose five-sixths of its weight, and that cut in March four-fifths. This view would give six loads of the finest hay as the annual produce of an English acre. There is good reason to believe that this may be near an accurate estimate, because the best meadows frequently, in the two mowings of May and July, yield more than at the rate of five loads per acre; but these are in the vicinity of the city of Milan, where the water that irrigates them is more fully impregnated with the rich drains from the city than that at a greater distance from it. From the last mowing in the beginning of

September, till the end of November, the cows are fed on Lombardy. the meadows. Thus, to the estimated crops of hay, must be added the value of this pasture for the cattle during about two months. The usual price for the best hay in the cities is about 40s. sterling the load. The cost of making it, where the weather is so settled as it usually is in Lombardy, must be trifling, and that, with the mowing and carrying, cannot exceed the value of the after-feeding, so that each acre will give a profit of L.12 sterling annually. It is not then surprising that such land can be sold as high as 1000 lire the *pertica*, or L.200 sterling the English acre, an occurrence by no means unusual.

The profit of these meadows does not arise from the sale of hay, which, in a country where few horses are kept for pleasure, must necessarily be very insignificant, but from the fattening of cattle in a small degree, and the operations of the dairy as the most important pursuit. The dairies are extensive, and carried on with the greatest care and most scrupulous attention to cleanliness. The dairy-farms in the three provinces of Milan, Lodi, and Pavia, are mostly occupied by persons of competent capital; many by the proprietors, and the rest by tenants who are not metayers, but have leases for a term never exceeding nine years, at a fixed money rent. They, unlike the farmers in other parts, are the owners of the live stock, and of the implements of husbandry, have comfortable dwellings, are well informed and active, and with diligence unite much economy.

The dairies of the three provinces of Milan, Lodi, and Pavia produce the best cheese, distinguished by the name of *Parmesan* in most parts of Europe, but in Lombardy commonly called *Formaggio di grana*, with the addition of *maggengo* or *invernengo*, according to the season in which it is made. The annual export of this cheese to foreign countries amounted to 1,800,000 pounds in the year 1824, besides what was consumed in the Italian and German provinces of the Austrian empire. At present, the annual produce is estimated at 51,520,000 lb., worth at least L.1,333,333 in the country itself in which it is made.

The operative part of making the cheese is confined to experienced practical men, who acquire a tact that enables them to time the several steps of the process with great accuracy, and without the aid of a thermometer to ascertain the requisite heat of the materials in each of these steps. From the nature of the climate, the milk will not keep long, but a cheese must be made every day. The cheeses are most valuable when they are large; and as the greater number of farmers have not milk sufficient to make such a cheese daily, the milk is sent by them to other farmers, so as to make up the requisite quantity. Sometimes four, or five, or more, small farms contribute their day's milk to one who has more stock, to make the cheese; and there are instances where the cheese-maker buys the whole of the milk from which his cheese is made.

The cows are milked evenings and mornings; in the first case about five or six o'clock, in the second at day-break, or just before. The milk of the evening is skimmed of what cream has risen on it before eight o'clock, and the milk of the morning, of that small quantity which is thrown up between day-break and that hour, and from that cream butter is made. Though the Parmesan cheese is thus made from skimmed milk, yet a very large portion of the cream is still left in it to enrich the cheese. The milk is then placed in a kettle, and warmed to the heat of 81° Fahrenheit, when the rennet is applied, the effect of which is increased by a small addition of vinegar, and sometimes of grated cheese, and a very small quantity of pepper. The other parts of the process so much resemble the practices in the best dairy-farms in England, as not to require any special notice.

It is salted after it is made, by sprinkling the surface

Lombardy. with that substance daily during six weeks, and turning the cheese to imbibe the particles. These cheeses vary in weight, when fit for sale, from 52 to 122 lb. avoidupois. They are kept some time before they are sold, a few at eight months, some at one or two years old, a less number at three, and a few at four years old. It requires much care to preserve the cheese against the heat of the climate. At Codogno and other places, where the wholesale trade is carried on, there are large magazines on the ground-floor, twenty feet in height, with shelves around, on which each cheese is placed singly. They have large windows, which are carefully shut to exclude the sun the whole day, but are opened during the night. It is difficult to estimate correctly the average quantity of butter and cheese produced from a given number of cows. On one farm, in the province of Lodi, there were 91 cows, from which were made 173 cheeses, varying in weight from 50 to 120 lb., but the weight of which the man who weighed them averaged at 100 lb. each. These had been made in the preceding six months and a half. Supposing the remainder of the year to be equally productive, the whole herd would have yielded, on an average, at the rate of 370 lb. in the year. There was, however, no certain account of the quantity of butter made on the farm during the period; and the quantity of cheese alone, though correct, does not give any certain data upon which to frame an estimate of the productiveness of the animals. The proportion which the cheese bears to the butter varies in the different irrigated provinces. Thus, according to the estimate of the accurate Signor Berra—

100 lb. of milk yields in Lodi $2\frac{3}{10}$ th lb. of butter, $6\frac{3}{10}$ th lb. of cheese.

100 lb. of milk yields in Milan $2\frac{1}{10}$ th lb. of butter, $6\frac{1}{10}$ th lb. of cheese.

100 lb. of milk yields in Pavia $1\frac{3}{4}$ th lb. of butter, $5\frac{8}{10}$ th lb. of cheese.

The farms in these provinces are generally small. One of 250 English acres would be denominated large; and though there are a few that exceed that extent, yet the greater portion of the irrigable land is occupied by farms much below one-half of that extent. Amongst the occupations that are confined exclusively to the *marcite*, or winter-watered meadows, many, perhaps the greater part, do not exceed forty acres. As the farms are small, so there are very few great proprietors. The family of Luoghi Pii have the greatest tract of the best land in the province of Milan, divided into many farms, and said to amount to 3000 acres. No other exceeds one-third of that extent.

The value and the rent of land depend less upon the natural fertility than upon the local situation, on the power of irrigation it can command, and on the capital expended on making roads to it, fences around it, and in erecting houses and agricultural buildings. In the vicinity of the city of Milan, those winter-watered meadows have the greatest value which are to the south, and are watered from the canal of Vettabbia, whose waters bring with them the precious manure of that populous place. The price of such land is about L.130 sterling the English acre, and, if it has good roads and buildings, may be let to good tenants at from L.6 to L.7 per acre. The land which has not sufficient irrigating power to form winter-meadows, but enough for the purposes of convertible husbandry, is worth from L.50 to L.60 per English acre, and may be let at from 60s. to 70s. per acre. In these cases the taxes and repairs are paid by the proprietor, as well as the contributions collected for keeping in proper repair the canal by which water is conveyed. Some parts of the irrigable provinces have lands of inferior natural quality, but being on the banks of the Po, are well calculated to grow rice, by their capability of being constantly flooded.

It is difficult for a stranger to generalize with any accu-

racy the value of land, or the rent of it in due proportion Lombardy to the amount of the sum invested on it. An opinion generally prevails that the capital laid out in land might be assumed to pay an annual rate of interest of about four per cent., but that as most of the rent, with the exception of the irrigated provinces, is paid in produce, those who employ factors to manage their property, or who manage it themselves, without great judgment and perpetual watchfulness, could scarcely calculate on obtaining more than three per cent.

It may serve to give some idea of the difficulty of ascertaining the amount of the rent of land, if a slight view be taken of the description of the classes of persons occupied in cultivation. The first of these is the *affittuario*, who somewhat resembles the middle-man now generally to be found in Ireland. They rent large portions of land at a money price, and let it out again to sub-tenants, who work it, if in small lots, by means of their own family, with an additional servant or two, or, if large, by day-labourers and their families, who are established on the property.

The next class is called *conduttori*, or *fittaiuoli*, or farmers. These are the most advantageous to the proprietors, and they are tolerably numerous, as well in the Venetian as in the Lombard provinces. This class comprehends the farmers in the watered provinces, whose chief object is the making of cheese, in some cases combined with the culture of rice. These lay out large sums at first, and have a good stock of cattle and utensils, and a sufficiency of capital. The advantage of this class to the proprietor is obvious. They take from him the labour of superintendence, and all risks from failing years and from loss of cattle; and, having leases renewed every nine, twelve, fifteen, or eighteen years, they can have no inducement to destroy the fertility of the soil. Though many of them have more extent of land, the greater proportion may be described as occupying from seven to twenty-five acres.

The third, and by far the largest class of all, are the *coloni*, colonists, sometimes called *pigionanti chiusuranti*, who occupy from an acre and a half to three acres of land, with a cottage. These premises they take either of the proprietors, of the middle-man, or of the farmers, and pay a rent by a share of the produce. Some colonists pay to their superiors a fixed quantity of corn yearly, or its equivalent in money and an agreed proportion of the other products, such as wine; or, in many cases, the whole of it is divided. When these shares are not too small, and the ground is fruitful, the most common custom is to pay a distinct measure of corn, and the half of the wine. The meadow land is paid for in money, in silk-worms' eggs, or in cocoons. The cattle, perhaps a cow and a donkey, are furnished to the colonist on credit, and if his terms are favourable, and he gets forward, he becomes the proprietor of them as well as of the utensils; but if the land is unproductive, or the shares of the proprietor too great, he must give up the cattle and the utensils, and may then be permitted to continue on the land, giving to the proprietor one-half the produce, or, if the crops prove heavy, a still larger share.

The farmers of the great estates in the watered provinces are in prosperous circumstances, and generally well educated persons; and their chief occupation consists in overlooking the workmen, and making the due bargains for the disposal of their produce. They are also necessarily furnished with some capital, as a proof of which, one near Lodi, occupying a farm of 250 English acres, upon which were 58 cows, a bull, and 8 horses, and who had on hand the cheese made in the six preceding months, asserted that the value of his stock exceeded L.800 sterling. On that farm there were 22 families of day-labourers. Six or seven men, the heads of those families, were in the constant employment of the occupier, either as herdsmen, ostlers, or

Lombardy. stable-servants. All the rest, and the females and children, were only employed when there was work to be done, for which they were paid daily wages, viz., to the men about fourpence halfpenny a-day, to the women threepence, and to their children from twopence to threepence, according to the age or strength. They had also one meal a-day, consisting of rice and beans, but no wine, and meat only one day in the year. Some of them were occupied, on fixed terms, in rearing articles that required much labour to prepare them, and received a proportion of the product. Thus, of flax they received one-half, of maize one-third or one-fourth, and of rice one-seventh. When not wanted they may get occasional wages on neighbouring farms. In most of their habitations they hatch a few eggs of the silkworm, if they can find money or credit to buy mulberry leaves; and if not, they have some occupation in winding the silk for those who are a little better situated.

In those provinces of Lombardy which are not to any extent capable of irrigation, there are few large farms and no substantial farmers. The greater portion of the land is divided into small allotments of a few acres, either directly by the proprietors, or through the management of middle-men. The real cultivators, called also colonists (*coloni*), with their wives and children, perform all the labour, and contract to deliver half of the raw produce to the proprietor.

Instead of two or three acres of land, a few tenants have from 15 to 20 acres, and are enabled to keep two or three cows, and perhaps a horse or a mule. The cattle and utensils are their own property. They pay a moderate money-rent for the corn land, and divide with the landlord in equal portions the wine and the cocoons of the silk-worms. Such persons, if they perform the work by the members of their own families, subsist chiefly on maize, use no wine, and otherwise practise the most rigid economy, though they do not become rich, may live in a respectable and comfortable manner.

The chief product which is furnished by Lombardy to external commerce is silk, which interests more or less every family in the country, and receives the greatest share of general attention. As the quantity and the quality of the silk depend on the worms that spin it, the subsistence of those worms becomes an object which engrosses much consideration. The leaves of the mulberry tree are exclusively the food of the worms, and the greater weight of these leaves that can be gathered, the greater is the silk that is produced. In many parts are numerous nurseries, where those trees are raised, with most careful cultivation, from seed.

The wild mulberry, or *Morus alba*, yields the best leaves for the nourishment of the worms, and the silk they spin whilst feeding upon them is of the finest quality; but the quantity of leaves they yield is so small, that it requires a great outlay and a great number of trees to give sustenance to an extensive silk establishment; on which account they are grafted with other kinds of mulberry trees, which have larger and dark green leaves, and in such abundance that they yield at least double the weight of leaves. The finest silk is obtained from the wild ungrafted mulberry tree; the next finest from one of a new species produced by grafting; the third from the grafted white mulberry; and the coarsest from the black mulberry. The fruit of none of these trees is in any estimation. In order to procure more leaves, the cultivators of the trees, every fourth year after the leaves have been stripped, cut off all the smaller branches quite close to the principal ones. In the succeeding year the leaves are not taken from the new shoots, but they are in the next and following years; and in the fourth year, the shoots are as bushy and thick as if they had not been tapped.

It is difficult to form an average of the produce of mul-

berry leaves from each tree, as much depends on the soil, Lombardy. but more upon the age of the tree. As soon as they have attained 6 inches in diameter, they yield from 19 to 27 lb., and continually increase their produce till they attain a diameter of 2 feet, when they yield from 220 to 260 lb. Having then attained their full growth, they continue to increase in produce till they yield in some cases, but extreme ones, as much as 500 lb. The market prices of the leaves undergo a great fluctuation, varying sometimes 100 per cent. in a fortnight.

Some persons who have none, and others who have but few mulberry trees, yet breed silk-worms. They are careful to make contracts for what they expect to want, in March or April, when they are cheapest. It not unfrequently happens, that by a storm of hail the price is so raised that the breeder, instead of drawing a profit from his operations, finds he has paid more for the leaves than he can obtain for the cocoons. There are persons so skillful in estimating in the spring the weight of leaves which each tree will produce, that their assistance is commonly resorted to by those who make bargains for the leaves. When the worms begin to spin they require such a quantity of food as to raise the price of leaves; and if at that time a hail-storm should occur, the advance becomes most ruinous to the purchaser. In general the mulberry trees are, by the terms of the leases, let to the farmers or colonists, who divide the cocoons equally with the proprietors of the land. The tenant provides half the eggs, and superintends the insects, feeding them, and keeping them clean whilst they are working; the other half of the eggs, as well as the leaves, are the contributions of the landlord to this equally-joint-stock concern. The tenant estimates what worms can be nourished by the quantity of leaves the trees upon his farm will feed, and the two parties procure the estimated weight of eggs. If the tenant miscalculates, or if a hail-storm destroys his calculation, he is bound to purchase such a portion of leaves as will feed the insects through their working period.

The eggs of the silk-worms are made an object of trade by a few persons whose establishments are upon so large a scale as to make it worthy their attention. They are sold by weight, generally at about 2s. the English ounce. The eggs are divided into three classes. The worm from the first of them casts its skin four times, and is of a large size, and an ounce contains 24,024 eggs. Supposing each egg to produce a caterpillar, and each caterpillar a cocoon, as 110 cocoons weigh 1 lb., the whole ounce of eggs will yield 218 lb. of cocoons. The second also casts its skin, but the animal is of a smaller size, as are the cocoons; 1 ounce of them contains 25,185 eggs, and the cocoons produced from them weigh less, 216 being 1 lb., and consequently the whole weight of the cocoons is only 96 lb. The third class casts its skin but three times; 1 ounce contains 31,004 eggs, 440 cocoons weigh about 1 lb., and the whole weight of the cocoons is only about 70 lb.

In every house room is made for laying out the worms and even in the poorest cottages of the colonists it is so contrived that some space is allotted to them. Tables of reed are formed, about $2\frac{1}{2}$ feet in breadth, and from 15 to 18 feet in length. These are suspended from the roof, the upper shelf 2 feet below it, and others at 1 foot distance, with the lowest of them 2 feet from the floor. The windows are made of paper, to prevent currents of cold air, and too great heat; the shutters are of straw, and the door consists of a piece of old linen cloth. Within, the place is kept in darkness, except when the worms are to be fed or the place cleaned out, when lamps are used. In many of these places, thermometers, made of spirit of wine, are kept to ascertain the temperature; and show no other change of heat than that between the 16th and 20th degrees of Reaumur, to which limit it is deemed necessary

Lombardy. to confine their range of temperature. Habit, however, has given a tact, by which the people ascertain the degree of heat with tolerable accuracy.

Some of the colonists within a season produce as much as 140 lb. of cocoons. Taking their half of them at 70 lb., and estimating them at the average price (for there is great variation in the price) of 1s. 6d. per lb., it will yield for a month's labour, L.5, 5s., which is a large sum for persons in that condition of life in that country. From it, however, must be deducted the cost of leaves, when the landlord's trees do not yield as much sustenance for the insects as the tenant has calculated when purchasing the eggs.

The planting of mulberry trees, and the consequent produce of silk, have been constantly increasing of late years. It is an object of attraction to every grade of society, from the greatest landholder to the lowest of the colonists and day-labourers, whose energy has been stimulated by the constantly advancing price of raw silk, with few exceptional years, from 1814 to the present time. It has been ascertained that three-fourths at least of the mulberry trees in the kingdom are under 40 years of age, and that one-half of that three-fourths are of less than 10 years' growth. The greater number of them are to be found in the dry provinces, though their plantation has increased much even in the irrigated districts. From Milan to Varese, from that city to Como, and between Lecco and Bergamo, the cultivation of vines has almost everywhere given place to that of mulberry trees. They are very numerous on the hills round Bergamo and Brescia. In the province of Verona, especially between that capital and Desenzano, and from Castelnuovo, through Vallego, quite to Roverbello, the surface of the country consists of masses of rounded pebbles, washed down at some remote period from the neighbouring Alps. As much strong soil is mingled with these stones which is favourable to the mulberry trees, vast numbers have been everywhere planted; but owing to a prejudice that prevails in these districts against the practice of engrafting, the quantity of leaves does not bear the same proportion to the number of trees as in some parts of Lombardy. Mulberry trees are found, with less annual expense, more profitable than any trees cultivated for their fruit. The average profit from each tree, from five to fifteen years old, is reckoned to be about five shillings sterling annually.

It appears from the official statistics, that the quantity of cocoons produced in the kingdom at different recent periods was as follows:—

	1848.	1852.	1856.
Lombardy....	19,755,519 lb.	33,513,826 lb.	41,892,283 lb.
Venice.....	12,964,559 ..	22,335,201 ..	22,776,173 ..
Total....	32,720,078 ..	55,849,027 ..	64,668,456 ..

Supposing these returns exact, the production of cocoons in the four years from 1848 to 1852 had increased by more than two-fifths; and if, in the subsequent four years, the increase is found to be less than one-thirteenth, it must be borne in mind, that both in 1855 and 1856 almost *one-half* of the produce was destroyed by the prevalence of disease among the silk-worms.

The 64,668,456 lb. of cocoons produced in 1856, at the low average price of 17½d. per lb., would give a value of L.4,336,360. According to the ratio shown by Dandolo, those 64,668,456 lb. of cocoons, whilst requiring for their production the enormous amount of 9,043,499,700 lb. of mulberry leaves, must have yielded at least 5,021,559 lb. of raw silk, which, at a low average price of 19s. 8d. per lb. for the 3,123,546 lb. belonging to Lombardy, and 16s. 7½d. per lb. for 1,898,014 lb. of the inferior kind of the Venetian provinces, would be worth L.4,647,686. The operation, therefore, of winding the cocoons into raw silk gave a gross profit of L.311,276.

Of that quantity of raw silk only 4,299,471 lb., worth Lombardy. L.3,965,000, were spun and twisted in the kingdom, viz., 2,976,557 lb. in Lombardy, and 1,322,914 lb. in Venice. The spinning and twisting manufactures gave employment for the average period of 50 days a-year,—in Lombardy to 4500 men, 5500 women, and 2000 girls, besides 30,000 women more (the *incannatrici*) in their own houses; and produced about 2,822,217 lb. of spun or twisted silk (*organzine*), worth, at an average of 23s. per lb., L.3,245,556;—in the Venetian provinces to about 18,000 persons altogether, and produced 1,256,568 lb., worth, at an average of 18s. 9d. per lb., L.1,178,000. The gross produce, therefore, of the spinning and twisting manufactures was, in Lombardy L.317,666, and in Venice, L.78,000. A comparatively small quantity of spun silk is consumed within the kingdom; much of it is sent to be manufactured in Austria Proper, in Bohemia, and in Hungary, and a much larger quantity is exported to France and England.

The subjoined table shows the distribution of the produce of cocoons over the various provinces in 1856:—

Produce of Cocoons in 1856.

Lombardy.	lb.	Venice.	lb.
Bergamo	12,126,700	Verona	9,921,850
Milan	7,717,000	Udine	3,968,754
Brescia	7,055,555	Treviso	3,307,275
Como	4,409,700	Vicenza	2,645,860
Mantua	3,527,778	Padua	1,102,425
Cremona	3,307,275	Rovigo	771,700
Lodi	2,204,850	Venice	661,425
Pavia	1,102,425	Belluno	396,884
Sondrio	441,000		
Total	41,892,283	Total.....	22,776,173
		Lombardy.....	41,892,283
		Total.....	64,668,456

After reviewing the productions of most value, the cheese and the silk, a slight notice may be taken of the results of those other operations of agriculture which are almost exclusively confined to domestic consumption.

Of corn crops, the most extensively grown is maize. It is the chief nourishment of the working classes, and is deemed by them the most healthy and most strengthening of all grain. It has, too, the advantage of being most easily converted into wholesome food, requiring, unlike wheat, no assistance from the baker. It requires only a kettle and a little fuel to make it into polenta, a kind of thick pudding or gruel, which, without any addition, forms the common food of the peasantry. It is also a valuable product on other accounts. The grains in a green state are a substitute for green peas; the leaves, when fresh, are a fodder, on which cattle eagerly feed, and, when dry, they are used to make excellent beds, or rather mattresses; the stalks are used for fuel in that country, where fuel is scarce; and, finally, the feathery tops are converted into brushes for sweeping the houses.

Maiz is also cheaper than wheat, being commonly sold at about two-thirds the price of that grain; but, from its being the food of the far greater part of the population, in seasons of great scarcity, such as those following the harvest of 1816 and 1828, the indispensable demand for it caused the price to rise higher than that of wheat. More than one-third of all the arable land of Lombardy is destined to the cultivation of this grain, and the average product per acre is greater than that of wheat. It is grown almost indiscriminately on all kinds of soil, and is to be seen equally on the cold hills and in the warm valleys of the provinces. The culture of it does not appear to have received any improvement since its first introduction. It is in some cases sown broadcast, and covered in with the plough. From this mode of sowing it, it can only be cleared of weeds by hand, and the earth is thrown round the plants in the same way; whereas,

Lombardy. in the countries where it is sown in rows or drills, these operations can be more advantageously performed by appropriate instruments. The expense of this hand-hoeing and shovelling up the earth is said to be equal to the value of one-third of the gross product of the crop. It is customary, after the bloom is off, to strip the plant of its leaves, and also to cut the stalks above the cobs or ears, which, if not done too early, is not injurious to the grain. There are several species of this plant. The most common is that with a large yellow grain, whose cobs grow about half-way up the stalk, and which ripens in three months, if sown in the month of May. If it cannot be sown so early, or if it is sown after a crop of flax, or on clover after the first mowing, it is usual to sow another kind called *brigantino*, whose grains are smaller, and of a darkish brown colour. In the vicinity of Bergamo, the greatest quantity of maize is of this kind. There are some species of this corn of much smaller grains, called *cinquante* and *quarante*, from the number of days which pass between the sowing and the harvesting. These kinds are commonly sown on the wheat stubbles, or after a crop of flax or of rape-seed has been gathered. It is seldom very productive, and, if the field on which it is sown be poor, scarcely repays more than the seed and the labour.

In a country where the soil and the climate are so various as in Lombardy, and where the difference in the quantity of manure applied to the soil is so great in the several portions, it is impossible to arrive at any average calculation of the produce of maize per acre. Nothing more can be done here than to state a few facts on the subject. One very accurate cultivator on the richest irrigable land, to which abundant manure was applied, stated that his crops yielded annually in a series of years from 59 to 78 English bushels an acre. Another also, in the same circumstances, a few miles distant, gave his range of bushels at from 50 to 78 per acre. The other side of the picture is vastly different. According to an official valuation in the revenue office at Milan, the following average of the produce of maize in some of the poorest provinces is given, viz., in Verona, the greatest produce is rated at 15 bushels the acre; in Vicenza, from 32 to 42; in Padua, from 12 to 21; and in Udine, from 13 to 22. No other provinces are noticed in the account. To this account of the average produce of maize may be added calculations made by two of the most accurate agriculturists of Lombardy. Count Dandolo informs us, that the average produce from the colonists on his estates near to Vanese, on whose fields the peasantry had been induced to plant the beans called *fisole* amongst the maize, was 21½ bushels of maize, and 4½ bushels of beans. The average on the whole of his estate, including the part cultivated by himself, is stated to be 32½ bushels of maize, and 7½ bushels of beans. Another intelligent agriculturist asserted, that, according to the best calculation he could make, and he had taken much pains on the subject, the average produce of maize did not exceed 25 bushels the acre, which he considered to be a produce one-third greater than that of wheat. The quantity of maize grown in the Lombard provinces in 1854, was, according to the official returns, 973,024 quarters.

Rice is a plant introduced from India and China at some distant but not very remote period. According to some, it was known as early as the tenth century; but no one large field was cultivated with it, until a patrician of Milan, in the year 1522, first destined to it some marshy land upon his own estate in the province of Verona. In the province of Pavia it is the most profitable grain that is grown; and in the provinces of Lodi, Cremona, Verona, Mantua, and Milan, it always secures to the farmer moderate benefit. The yearly produce is about 165,072 quarters, much of which is consumed at home, as those who do not subsist on maize alone have one meal a-day of this article. Some of

it is exported, but the amount of that portion falls far short Lombardy. of the quantity imported for home consumption. Rice is a marsh plant, and can only be grown where the land can be covered with water. The evaporation is injurious to human health, and hence laws are enacted regulating the distance which must intervene between the rice-fields and the cities and towns. Without these restrictions, rice would be more extensively cultivated. Some portion of rice is grown in the rich provinces, as one of the crops in rotation of convertible husbandry. In this practice, called *risare a vicenda*, it is most commonly sown after clover. The land is ploughed very deep, but not harrowed. The water is then turned on, so as to cover the surface, and to show any inequalities which remained by the use of the spade. The seed is then sown, or rather scattered on the water, having been previously steeped during eight or ten hours to give it additional specific gravity, so that it may sink immediately to the bottom. If it were sowed after clover, two bushels of seed would be sufficient for one acre. When it is sowed, as is oftentimes the case, after maize, the quantity is usually three bushels.

The time of sowing is from the beginning of April till the middle of May. It remains covered with water to the height of from 2 to 3 inches, and in that state remains till weeding becomes necessary. That early sown requires the operation to be performed in the middle of May; that later sown, some time in June. It is executed chiefly by the females, who, with their lower garments tucked up, stand in water over the ankles, and with the hand pluck up the weeds by the roots. If the land were dry, the weeds would break off, and leave the roots to shoot out again. The most prevalent weed is the cockfoot grass, which, at an early period, it is difficult to distinguish from the rice. Besides this, there are several other weeds, chiefly of the rush kind. In the first year the operation of weeding is performed twice. If the same field be sown with the rice in the next year, once is deemed sufficient. This is the most expensive part of the process, and is said in the first year to require 25 days' work for an acre, which, as the employment is unpleasant and unhealthy, is commonly paid for at the rate of about 10d. per day. Much of this work is executed by the colonists upon plans marked definitely in their leases. The terms vary excessively, according to the locality and the soil. A common plan is, for the colonist to receive one-quarter of the gross produce, after the quantity used as seed has been abstracted from it. For this he is bound to perform the following portions of the labour, viz., the levelling of the surface, the sowing, the weeding, the reaping, and all the labour not performed by cattle, until the crop is placed on the threshing-floor. In the case of some of the poorest land, the colonist receives one-third instead of one-fourth, of the produce. About midsummer-day the water is allowed to run off the land, and during eight or ten days it is suffered to become dry. This is done to destroy the numerous water insects, which would prove injurious to the roots of the rice, and cause it to fall into the water.

Wheat is a grain not extensively cultivated in most parts of Lombardy, excepting in that portion of it which comprehends the mountainous Alps. There is but one species of it,—a winter wheat, sown between the first week of October and the first week of November; but the best farmers wish to finish their sowing by the 21st of October, if the season permit. The wheat is all of the bearded kind, the preference of which has been owing to the opinion that the beard is a protection against the fogs of the blooming season, and against the depredations of the small birds at the time of the grain ripening. The produce is a kind of wheat harder than that of the W. and N. of Europe; and from this circumstance it is better calculated to be converted into macaroni than our wheat would be. The

Lombardy. product of the crops is less per acre than it is generally in the German dominions of Austria, and less than in England or in the best parts of the Netherlands.

It is of course most productive on the best lands of the rich provinces, where irrigation is practicable to the exact extent which the nature of the crop may require. On that description of soil it is less profitable than other crops, and, therefore, only a small portion is applied to its growth; but even on the best of that land it is a rare event to obtain sevenfold the quantity of the seed that has been sown. In the neighbourhood of Mantua, where the poor colonists grow wheat and maize in alternate years, where the soil is sandy, and where, from the paucity of cattle, little manure is applied, it does not appear that the crop of wheat grown more than equals four times the seed.

In Verona, the higher part of which is stony, and the lower part sandy, the best of the land yields 10 bushels, and the worst only 6½. In Vicenza, where the soil is better, the lands of the first quality yield 18 bushels, those of the second 15, the lowest 12. In Padua, the first class of lands yields 15½ bushels, the second 11½, and the lowest class only 7 bushels. In Udine, a poor sandy soil, mixed with many pebbles, and where there are but few cattle, the first class of soils yields 10½ bushels, the second 9, and the lowest only 6½.

It is not easy to ascertain what portion of the fields is appropriated to the growth of wheat. On the best of the soils, according to the regular rotation of crops, one-half of the land is in grasses, the proportion of maize is greater than that of wheat, and some portion is sown with pulse, rye, millet, oats, flax, hemp, and other kinds of crops. In 1854 the wheat produced in Lombardy alone amounted to 697,186 quarters. The other kinds of grain are but very little cultivated.

Few things are more striking to a visitor in Italy from the N. of Europe, than the straight rows of trees of all kinds that run through the corn fields, at the foot of which vines are planted and trained, so as to extend in elegant festoons from one tree to another, exhibiting the pendant clusters of grapes. If the same mode of training the vines were attempted in the somewhat colder climates of France and Germany, the shade of the trees would prevent the grapes from ripening. This effect is not produced in Lombardy, where the berries become ripe, and, when eaten, are of good flavour; but the wine produced from them is in general of a bad or very indifferent quality. Though much of the wine is produced from such vines in the corn fields as are distinguished by the names of *Campi Arativi Vitati*, or of *Campi Arborati Vitati*, and from vines planted in rows at such a distance from each other as to admit of maize being grown between them, and called *Ronchi*; yet in some parts are vineyards properly so called, because, like those of France and Germany, they alone occupy the ground, and are, like them, supported by props. The best wine is produced from the *Ronchi*, and more especially from the vineyards properly so called, in which, however, each vine produces less in quantity than those trained from tree to tree. The amount of produce varies greatly according to different years, different districts, and different modes of cultivation. From an approximate estimation made on many farms of various soils, it would appear that, in the most productive districts, the average produce of large vines trained to the trees around the corn fields is from 48 to 52 gallons for 100 vines; and the average produce of vineyards properly so called, from 58 to 65 gallons of wine to the acre.

In Lombardy the wine is generally of a bad quality. Its production is left chiefly to that description of cultivators before noticed under the name of colonists, who exercise little discretion and little care, either in the choice of the kind of grapes they plant, or in the management of

the juice. Their chief care is to obtain the largest quantity, without much regard to the flavour or the aptitude of keeping; and commonly, as soon as it is made, they divide it in equal shares with their landlords. One cause to which the inferiority of the wine is attributed arises from the general predilection in favour of red wine, or, as it is called, *Vino Nero*, which is prized according to the darkness of its colour. In order to produce this deep colour, the skins of the grapes are left, in the first part of the process, to ferment with the juice. Sometimes this is suffered to continue during eight or ten days in a vat before the liquor is drawn off, and sometimes still longer, as the longer it continues the darker the wine becomes. The best wines are produced in the district near Varese, on the sunny slopes of the hills round the lakes of Como and Garda, and in the Val Calcepio in the province of Bergamo. The wines of the localities of Sassella and Inferno, in the Valtellina, maintain the ancient renown of the Rhaetian wines, relished by Augustus and celebrated by Virgil.

The wine of the Venetian provinces is, upon the whole, of a much better quality; its superiority is owing to the nature of the soil, to a better choice of the kinds of grapes that are planted, and to the more careful preparation of their juice. The best qualities are produced in the province of Treviso, in the Berici and Euganean Hills, between Vicenza and Padua, in some districts of the province of Udine, and above all in the province of Verona, well known for its *Valpolicella*, the best common wine in the kingdom.

There is no old wine in the country, except in small quantities, and in the hands of a few amateur proprietors. The wine of each vintage is sold in the course of the following year; and when any of it is kept, even though it should not have become, or shown a tendency to become, vinegar, it will sell at a lower price than new wine, because it is milder, and less agreeable to the taste of the consumer.

Previous to 1851 the annual quantity of wine produced in the kingdom, in average years, was 85,837,705 gallons, of which 52,823,203 gallons were produced in the Venetian, and 33,014,502 in the Lombard provinces. The produce of Lombardy not being sufficient for the consumption of its population, nearly 4,402,000 gallons a-year more were imported either from the Venetian provinces, which produced much more than was required for their own consumption, or from the neighbouring states of Modena, Piedmont, and the Papal territory, according to the respective local produce and prices. But since 1851, when the *oidium* attacked all the vines of the country, the produce has so fearfully diminished that in 1856 the government found it necessary to grant a reduction of the direct land-tax on lands chiefly cultivated with vines, in proportion to the ascertained amount of loss. The whole produce of Lombardy, in 1852, was reduced to 11,004,834 gallons, and that of the Venetian provinces, in 1854, to 7,538,311 gallons of wine. The respective loss of each province was as follows:—

Government of Milan.		Government of Venice.	
Gallons of Wine produced in—			
1838.	1852.	1847.	1851.

Potatoes, which form so important a part of the food of the inhabitants in the more northern parts of Europe, are

Lombok
|
Lomond,
Loch.

very little cultivated in Lombardy. They are almost exclusively confined to the Alpine districts, or, when grown on the level country, are confined to the gardens. The absence of this root is a subject of sincere regret to the most patriotic individuals who have devoted their attention to rural economics. Count Dandolo attributes much of the dreadful consequences which followed the deficient harvests of 1816 and 1828, when great numbers perished from want of common necessities, to the absence of that seasonable supply of food which potatoes would then have furnished. Others have made similar and ineffectual remarks. The taste for polenta is much too deeply rooted, and the dislike to potatoes so common amongst the working classes of the rural districts, that there is no present prospect of their cultivation being speedily extended.

It is generally believed that more than four-sixths of the inhabitants of Lombardy subsist wholly by the labours of the field. Of these, the far greater proportion are of the description which is here called colonists. They are small occupiers, dividing the trifling products of the soil with the proprietors. Their dwellings are small, their furniture and utensils scanty, and their dress of the coarsest materials. They generally marry early, and have families, though they have no prospect of supporting them, beyond the hope that the half of the produce of maize on a few acres of land may yield them food during the year, with the exercise of the greatest parsimony in its use. In the event of sickness, they have to resort to hospitals and charitable institutions. The charity of those who can afford it is bestowed with as fair liberality as can be expected, considering the numerous claimants that offer for its reception.

The mining operations are inconsiderable, and are confined to the procuring of iron in the Alpine valleys of Bergamo and Brescia, and of copper in Belluno.

The manufactures of the kingdom, with the exception of that of silk, which gives the most employment, and has already been referred to, are not extensive, but have of late

years been on the increase. There are 33 cotton-spinning mills, of the power of 728 horses, and turning, in the aggregate, 123,402 spindles. The cotton for their consumption is introduced from Asia and America. In 1854 they spun 7,412,160 lb. of cotton, of the value of L.264,718; 3810 persons, of whom 1482 were men, 1152 women, 506 boys, and 670 girls, found at these mills a daily employment, and received, on an average, each man from 1s. to 1s. 4d., each woman from 7d. to 8d., and each boy or girl from 3½d. to 6d. per day. Cotton-weaving machines in 1845 had 15,602 looms, which in 1854 had increased to 17,014. As they are chiefly carried on in a small way by families of the lower classes, they gave employment to 34,000 persons. Their produce is reckoned at an average value of L.544,948 per year. The woollen manufactures employ about 700 persons, but are comparatively insignificant. There are only 3 flax-spinning mills, which turn 11,518 spindles, and employ 330 men, 220 women, 64 boys, and 258 girls. Venice has long been known for its glass manufactures; the annual average exports of glass, pearls, and beads of the last ten years has been L.143,333, of which the largest items were,—L.25,000 to England; L.15,666 to Calcutta; and L.12,666 to France. Milan has been from remote times celebrated for its weapons and arms; and iron work of all kinds is still extensively made in the province. Besides the great branches of manufacture, most of the smaller ones are carried on, especially those of paper, glass, gold and silver articles, and domestic utensils.

The foreign trade is not material; and that of Venice has much declined since its union with Austria. There are still, however, many ships navigating the Adriatic and the Mediterranean Seas, now bearing the Austrian flag, which are built and equipped at Venice. But there is no reliable information as to the real present amount of imports and exports, and foreign trade in general; and such returns as have been published, being *very far* from correct, would only lead to erroneous conclusions. (* * *)

LOMBOK, an island in the Indian Archipelago, lying between S. Lat. 8. and 9., and E. Long. 115.40. and 116.40.; and separated by the strait of Lombok from the island of Bali on the W., and by that of Allas from Sumbhawa on the E. It is about 53 miles in length from N. to S., by about 45 in breadth; and has an estimated area of 1480 square miles. Two mountain chains extend along the N. and S. coasts inclosing a well-watered plain, which is laid out in rice fields. On the slopes of the mountains, maize and coffee are reared. In the northern mountain chain is a volcanic peak rising to the height of 12,380 feet. The rivers and streams are numerous; and along the coast are several excellent harbours and roads. The staple production is rice, which is cultivated with great care, and large quantities of which are exported. A considerable trade is carried on at Ampanam, its chief port. The capital of the island is Mataram. Pop. estimated at about 250,000. Lombok is claimed as a dependency by the Dutch.

LOMOND, LOCH, the largest and most celebrated of the Scottish lakes, separating the counties of Dumbarton and Stirling. It lies nearly N. and S., and is about 25 miles in length. The southern portion of the lake for nearly one-third of its entire length forms a wide basin of from 3 to 7 miles in width, and contains about 30 islands, several of which are well wooded. The northern portion is very narrow, averaging little more than a mile in width. The loch is deepest in the northern part, where it attains above 100 fathoms, but gets shallower as it expands towards the S., where its general depth is under 20 fathoms. The surface of the water is 22 feet above sea level. Many streams contribute to its waters from the surrounding up-

lands, the chief being the Endrick, which joins the lake at its S.E. angle, and the Falloch Water at its head. The only outlet is by the Leven, which joins the Clyde at Dumbarton, after a course of seven miles. This stream, however, has become much obstructed where it receives the waters of the loch, and consequently, after heavy rains, discharges the surplus with difficulty. It has been supposed that this is the main cause of the lake's surface having risen of late years above what was considered its natural level. Conspicuous among the scenery that beautifies the loch is the lofty Ben Lomond, which rises to the height of 3192 feet above the level of the sea. A steamer plies on the lake in connection with the Dumbarton Railway, which terminates at Balloch. It appears from old chronicles, that the shores of this lake were at one time very productive and thickly peopled. In 1263 the Norsemen under Angus, King of Man, after having ravaged the shores of the adjoining Loch Long, drew their boats over the neck of land which separates the two waters at Taret, massacred the inhabitants who had taken refuge in the islands, and set fire to the numerous villages they found on the shores of the lake. After this expedition, the loch came into the hands of some of the chief Highland clans, who long carried on their feuds here. Of these, the Macfarlanes and Macgregors are the most famous, from the sufferings they latterly endured at the hands of their more powerful neighbours. Estimated area of loch, 28,000 acres.

LOMONOZOF, MICHAEL WASITOWITZ, the father of Russian poetry and literature, was born in 1711, at a village near Cholmogory, in the government of Archangel. In his boyhood he assisted his father in his humble calling

Lomono-
zoff.

London. of a fisherman, and with the aid of a priest during the long winters, acquired the art of reading. The perusal of Polotski's poetical version of the Psalms, one of the few books he had, developed his genius for poetry, and excited in him a thirst for literary fame. Accordingly, repairing of his own accord to Moscow, he entered the Zaikonospaski Monastery, where he applied himself chiefly to the study of the learned languages. After a short interval spent at the University of Kiev, he removed in 1734 to the newly-instituted Academy of St Petersburg, where he devoted two years to mathematics and natural science. He was then sent, at the expense of the Academy, to study under Christian Wolf, at Marburg in Hesse-Cassel. Here, during his intervals of leisure, he perused the German poets, a study which he continued when after the lapse of four years he removed to Freiberg in Saxony, to acquire a practical knowledge of mineralogy and mining under Henckel. On his return to St Petersburg in 1741, he was elected an associate of the Academy. He was appointed in 1745 professor of chemistry; and in 1760 rector of the gymnasium and university. In 1764 he was honoured by the Empress with the title of counsellor of state. He died in April 1765, and was interred with great honour.

Lomonozof's multifarious labours comprise translations into Russian from several languages living and dead, and treatises upon meteorology, chemistry, criticism, rhetoric,

history, and chronology. He may be said by his grammar to have drawn out the plan, and by his poetry to have built up the fabric of his native language. Besides several odes and translations in verse, he wrote an heroic poem in two cantos on Peter the Great, a work said to be unsurpassed by any Russian poet. He also produced *Annals of the Russian Sovereigns*, and the *History of Russia from the Origin of that Nation to the Death of the Great Duke Yaroslav I.* The latter has been translated into German and French. The principal works of Lomonozof have been published in 3 vols. 8vo.

LOMSHA, or LOMZA, a town of Russian Poland, capital of a cognominal circle in the government of Augustovo, on the left bank of the Narev, a tributary of the Vistula, 94 miles N.N.E. of Warsaw. It is situate in a wooded valley, and contains some spacious and well-paved streets. The principal buildings are, an arsenal, a Piarist college, a gymnasium, and several churches and convents. The manufactures are chiefly confined to iron and paper. Pop. (1854) 5804.

LONATO, a town of Austrian Lombardy, delegation of Brescia, and 14 miles E.S.E. of the town of that name. It is situate on a height about 3 miles from the southern shore of Lake Garda, and is surrounded by walls, and further defended by a citadel. Here Bonaparte gained a victory over the Austrians in 1796. Pop. about 6000.

Lomsha

London.

L O N D O N.

(LATIN, *Londinium*; French, *Londres*; Italian, *Londra*), the metropolis of the British Empire, and one of the greatest cities of ancient or modern times, is situate on both banks of the Thames, about 45 miles above its mouth at the Nore, and 15 below the highest tideway. Though chiefly within the county of Middlesex, London includes parts of Surrey and Kent, and extends into Essex. St Paul's, the most striking object in the city, is in Lat. 51. 30. 48. N., Long. 0. 5. 48. W. of Greenwich.

In dealing with so important a subject, it will, perhaps, be expedient to treat shortly of its various branches in the following order, viz:—

I. Rise, progress, and present extent of London.

II. Number, occupations, and social condition of its inhabitants.

III. Religious worship and education.

IV. Parks, palaces, public buildings, and institutions.

V. Civic government, police, defence, representation, &c.

Origin.

Its early history is lost in obscurity, and the first authentic notice of its existence is that of Tacitus (*Annal.*, lib. xiv., cap. 3), who, in alluding to *Londinium*, says, "Cognomento quidem coloniae non insigne, sed copia negotiatorum et comaeatuum maxime celebre." The derivation of the name "London" has been the subject of much conjecture, but that mentioned by Pennant (*London*, p. 17) seems most feasible, viz., Llyn Din, from *Llyn*, in Celtic, a lake, and *din*, a town. It could not, however, have been a place of importance at the period of Julius Caesar's invasion, as it is not noticed in his *Commentaries*. About 100 years thereafter the Romans, under Claudius, took possession of the city, and called it *Augusta*, in honour of that prince. It was erected into a praefecture; and the inhabitants, nominally citizens of Rome, were governed by Roman laws and Roman magistrates.

London was not fortified at an early period of the Roman occupation; for in A.D. 61, the Britons under Boadicea revolted, captured and burned the city, and massacred the inhabitants. The city was soon, however, rebuilt, but is supposed to have remained open till the reign of Constantine the Great. From the number of coins of his time

found under the walls, it may be inferred that that emperor constructed the walls; and it is alleged that he made London an episcopal see. The limits of these walls have been pretty exactly ascertained. They commenced near the site of the present Tower, extended along the Minories and back of Houndsditch, across Bishopsgate Street, in a straight line, by London Wall, to Cripplegate; thence southward to Aldersgate, proceeding afterwards by the back of Christ's Hospital and Old Newgate, passing behind the site of Newgate Prison, and so reaching Ludgate; again proceeding westwards to the River Fleet, and terminating at a fort called afterwards Baynard's Castle. Their compass was completed by another wall along the bank of the Thames. Extent of the walls, from and to the side of the river, 2 miles and 1 furlong; on the bank, 1 mile and $\frac{1}{10}$ th; uniform height, 22 feet. Through gates in these walls roads led to different parts of the kingdom. The great Roman roads, Watling Street and Ermin Street, had their termini at the London Stone, or Roman Milliarium, a portion of which still remains, and is inserted in the most conspicuous part of St Swithin's Church, abutting on Cannon Street. The names of the gates are still preserved in streets, &c.—viz., Ludgate, Aldersgate, Moorgate, Bishopsgate, Aldgate, Newgate, Cripplegate, and Postern Row, on Tower Hill.

After the Romans withdrew their forces from England, London suffered severely till the Saxons fixed themselves in the country. It is said to have become then the capital of the East Saxon kingdom; at any rate, it quickly regained its former importance, and is called by Venerable Bede a "princely town of trade." Soon after the introduction of Christianity, Old St Paul's, and St Peter's at Westminster, were founded.

When the Saxon monarchies were united in the person of Egbert, London became the capital of the consolidated kingdom, and such it has continued to be. In the reign of Alfred it recovered from the effects of the Danish invasion, as well as from those of a fire, which nearly consumed it in 893.

After the battle of Hastings, the city submitted to Wil-

London. liam, who granted it a charter, still extant; and who commenced building the Tower of London in 1078. About this time the capital suffered severely and frequently by fires, especially in 1077 and 1086.

In the following reign it was visited by a hurricane and an inundation; the latter carrying away the first wooden bridge over the Thames. Henry I. granted a new charter to the city in 1100, restoring the privileges it enjoyed previous to the Conquest, and conferring on the citizens the right of electing their own magistrates. It is said that this document served as the model for Magna Charta. The population in 1141 was estimated by Peter of Blois at 40,000. The title of the chief magistrate was changed by Henry II. from Portreeve to Bailiff; and in 1191 he is called Lord Mayor in a document issued by the Court of Aldermen. In 1198 Richard I. committed the duty of fixing a national standard of weights and measures to the sheriffs of London and Middlesex. John, by several charters, conferred additional favours on the city; among others, the jurisdiction and conservation of the Rivers Thames and Medway; and the power of choosing sheriffs.

In 1221 the first stone of the present Westminster Abbey was laid by Henry III.; and in 1236 water was conveyed in pipes from the village of Tyburn to the city.

In 1258 and 1270 the city was visited by famine, and in 1348 by a species of plague, on all of which occasions it suffered grievously.

Under Edward I. London was first divided into twenty-four wards, each to choose common councilmen and an alderman. Edward II., in 1316, prohibited as a nuisance the burning of coal, then lately introduced, but his mistake was soon discovered and rectified. Under Edward III. the city received the perpetual right of magistracy over Southwark. In 1381 the citizens were alarmed by the insurrection of Wat Tyler, but this was soon suppressed. Street lamps were first used in 1416. In the wars of the Roses, London chiefly favoured the interests of the House of York; and after the battle of Barnet, in 1471, Edward IV. knighted the mayor, recorder, and twelve aldermen. This was the era of the first printing-press, constructed and worked by Caxton in Westminster Abbey; as well as of the erection of water cisterns and conduits in several parts of the city and suburbs.

In the reign of Henry VII., a disease called the "sweating sickness" carried off two mayors and six aldermen, with many citizens. Some considerable improvements were made in this reign, as well as in that of Henry VIII., to which the suppression of religious houses by the latter materially contributed; these giving way to schools, hospitals, and charitable institutions.

Thanks to the wisdom of Elizabeth, the prosperity of London rapidly advanced during her reign. The refugees from the Netherlands introduced numerous manufactures before unknown in England, and in this way conferred especial benefits on London.

By maps of the time of Elizabeth and James I., it may be seen that the chief part of London then consisted of Newgate Street, Cheapside, the Poultry and Cornhill, and the various streets and alleys leading from them to the Thames. Along the Strand, towards Westminster, were houses on both sides—those to the S., and abutting on the river, being the palaces of the chief nobility. The names of Salisbury, Norfolk, Buckingham, Arundel, Essex, &c., have been perpetuated in the streets now on the sites of palaces and gardens formerly belonging to these families. Spring Gardens formed a series of walks, with bowling-green, &c., extending from Charing Cross towards Whitehall Palace, whence to the Abbey there was a regular street. On the Surrey side, there were not ten buildings between Lambeth and the west foot of Blackfriars Bridge; but from that point a row of houses was continued to the Borough. Southwark then extended but a short distance along High Street; and there

were small scattered houses from Tooley Street to Horselydown. In the reign of James I. brick was introduced as a substitute for wood in London houses, and the streets were first paved with stones. The city was severely visited by the plague in 1604, and again in the reign of Charles I. During the civil wars, a majority of the corporation took part with the Commons, and the city treasury was of great service to their party.

After the Restoration London began greatly to revive; but a serious check was given to it by the last visit of the plague, which raged from June till the end of December 1665, and destroyed nearly a third of the population. This was speedily followed by the "Great Fire," which commenced 2d September 1666, lasted four days and nights, and in that time reduced to ashes five-sixths of the whole city within the walls. The ruins covered a space more than a mile long and half a mile broad; and the value of buildings and goods consumed was estimated at ten to twelve millions sterling. But though severe at the time, this visitation contributed materially to the improvement of the city. It was rebuilt on a more commodious plan by Sir Christopher Wren in about four years. From the time of its reconstruction, few stirring events occurred. The first stone of St Paul's was laid in 1675. The revocation of the edict of Nantes in 1685 brought to London many French Protestant families, who peopled Spitalfields, and introduced the manufacture of silk. The continued growth of the city in the reign of Queen Anne occasioned the act of 1711 for building fifty new churches, the cost being paid by a tax on all coals brought into the Thames. The streets were then first generally lighted; fire-engines were provided, and measures taken for watching the city. In her reign, Clerkenwell, Old Street, the lower part of Shoreditch, Marlborough Street, Soho, Bedford Row, Red Lion Square, and a district north of Holborn, were annexed to the metropolis.

In the reign of George I. some additions were made to London, chiefly to the north of Oxford Street and about Berkeley Square. In the reign of George II. some new parishes were erected, viz., St George's, Bloomsbury; St Ann's, Limehouse; St Paul's, Deptford; and St Matthew's, Bethnal Green. The River Fleet was covered, and a market built on it; Grosvenor Square, Westminster Bridge, and Great George Street were built; and roads were formed in several directions, the principal one skirting the northern part of the city from Paddington to Islington.

The accession of George III. gave a fresh stimulus to improvement and extension. A new bridge at Blackfriars, with handsome streets leading to it, and many new dwellings on the Surrey side, were erected. On the N.W. side the parishes of St Pancras and Marylebone were formed. At the same period the street pavement for foot passengers was first laid down, the kennels removed from the middle to the sides of the streets, and the numbering of houses introduced. The American war gave a temporary check to extension; but soon after the peace of 1783, the advance became more rapid than ever. Docks were constructed, the commerce of the city rapidly augmented, the ground near the water side was covered with buildings, and, westward, Bedford, Russell, and Brunswick Squares quickly sprung up. From the Regency in 1811, London advanced in extent and in elegance still more rapidly. Regent's Park was formed, and surrounded by handsome terraces; and within the last few years the extensive and fashionable districts called Belgravia and Tyburnia—the former to the south and the latter to the north of Hyde Park—have been created, and literally covered with houses of a high class. In 1851 there were 305,933 inhabited houses in the metropolis, and there are no less than 6300 streets enumerated in the *London Postal Guide* for January 1857.

London.

Recon-
struction
and growth
of London.

London. It is difficult to assign any distinct boundaries to the metropolis, as almost continuous lines of houses stretch like branches from the main trunk of London, to Chiswick, Kensal Green, Kilburn, Hampstead, Highgate, Stamford Hill, and Upper Clapton in Middlesex; Stratford and North Woolwich in Essex; Greenwich and Lee in Kent; and Dulwich, Norwood, Clapham, Wandsworth, and Putney in Surrey. These, too, are constantly increasing in length and breadth; the vacant spaces between distant lines of road being filled up with extraordinary rapidity. The circle formed on a radius of 4 miles from Charing Cross excludes a large portion of London; but its extreme length may be set down as 10 miles, and its breadth at about 6. There are

four divisions of the metropolis which, though rather vague, are pretty generally understood by Londoners,—these are, the City, the West End, Lambeth, and the Borough; the two first on the Middlesex, and the others on the Surrey side of the water. The city of London proper has an area of 725 acres, and contains 108 parishes,—97 within, and 11 without the walls. In its most limited sense, the metropolis includes the cities of London and Westminster, the parliamentary boroughs of Tower Hamlets, Finsbury, Marylebone, Lambeth, and Southwark. Annexed is an account of the population of the various cities and boroughs above mentioned, as ascertained by the different censuses, beginning with the first in 1801:—

London.

Boundaries
and divi-
sions.

Cities and Boroughs.	1801.	1811.	1821.	1831.	1841.	1851.
London City	156,859	120,909	125,434	122,863	120,702	127,869
Westminster ditto	158,210	162,085	182,085	201,842	219,930	241,611
Tower Hamlets Borough.....	184,568	237,487	291,650	357,246	419,730	539,111
Finsbury	134,616	167,130	201,731	259,123	265,043	323,772
Marylebone	97,642	126,566	174,354	240,294	287,465	370,957
Lambeth	49,886	76,806	108,565	160,563	197,412	251,345
Southwark	94,813	103,763	123,663	134,117	142,620	172,863
Total	876,594	994,746	1,207,482	1,476,048	1,652,902	2,027,528

The metropolitan district comprised within the bills of mortality includes, with the cities and boroughs embraced in the foregoing table, other integral parts of London, like Chelsea, Brompton, and Kensington; and the suburbs, such as Greenwich, Wandsworth, Hammersmith, Putney, &c. In this view, the area of the metropolis is 78,029 acres, comprising 186 parishes, and the present population may be estimated at upwards of 2½ millions. Annexed is an account of the population of this area at the date of each census, commencing with 1801:—

Years.	Population.	Years.	Population.
1801	958,863	1831	1,654,994
1811	1,138,815	1841	1,948,417
1821	1,378,947	1851	2,362,236

But many merchants and citizens, taking advantage of the easy access to the country afforded by the railways, occupy houses at such places as Kingston, Esher, Walton, Richmond, Twickenham, Staines, Windsor, Reigate, Brighton, &c., making daily journeys to and from the city, so that they and their families are not included in the foregoing account.

Situation
of London.

The situation of London, on the banks of a great tidal river, is also peculiarly favourable for a large city, in a sanitary point of view. The subsoil is partly clay (the London clay of the geologist). The valley of the Thames has a gradual ascent on the north side; and the south side, though below the level of spring tides, has been well secured against inundations by embankments. The air is temperate and rather dry than moist, and the health of the inhabitants has gradually but rapidly improved from the earlier part of last century, when the deaths were annually one in twenty of the population, whereas at present they are about one in forty.

Health,
mortality,
&c.

It may therefore be safely affirmed that, in proportion to its population, London is much more healthy than any other great city. The registrar-general and Board of Health, however, point out in their various reports to Parliament how much more salubrious are some parts of the metropolis than others. But London, comparatively healthy as it is, has been in times past, and is still, occasionally visited by pestilence. The great plague of 1665 and its ravages have already been mentioned; but at that period open drains and filthy habits were the order of the day. From the bills of mortality for 1665, it appears that 97,306 burials took place, of which 68,596 were those of victims to the plague; while the total baptisms were 9967.

In 1854 there were 84,885 births and 73,697 deaths in London; but the rate of mortality in that year was greatly increased by the cholera, no less than 11,661 persons having

died of that disease. This mortality from cholera, however, large as it appears, was less than that of 1849; the deaths in the latter being at the rate of 62, and in the former of 43 to every 10,000 persons living.

Annexed is a statement of the annual rate of mortality per cent in London and the whole of England during each of the five years ending with 1854:—

Deaths to 100 Persons Living.

	1850.	1851.	1852.	1853.	1854.
London.....	2.104	2.339	2.258	2.435	2.929
England.....	2.077	2.199	2.236	2.238	2.352

Fevers and pulmonary diseases are those most fatal in the metropolis.

In 1851 there were in London 3149 independent gentlemen, and there were also 4674 male and 22,284 female annuitants.

We extract from the population returns of 1851 and subjoin a classified statement of persons, distinguishing their sexes, employed in the chief trades and professions in the metropolis:—

Trades and Professions.	Males.	Females.	Total.

Commerce. As one of the great occupations of its inhabitants, the commerce of London demands the first notice. The capital of a great empire, with immense wealth concentrated in it, having easy access, both by land and water, to all parts of the kingdom, and every facility of communication with foreign countries, London has become, with perhaps the single exception of New York, the greatest commercial city in the world.

Thames. The commercial growth and prosperity of London are especially to be ascribed to its great river-port, the Thames. This famous stream has its source within the borders of Gloucestershire, a little to the S.W. of Cirencester, and becomes navigable at Lechlade, 138 miles above London. It is first affected by the tide about 15 miles above the metropolis; but before reaching this point, it is swollen by junction with the Isis, Kennet, Coln, and Wey. The city corporation are the chief conservators of the river, and appoint a navigation committee, who superintend the towing-paths, bridges, water-courses, and whatever relates to the river, as far as a stone a little above Staines Bridge. Higher up, the supervision is divided between the city and a body chiefly composed of the landowners on both sides of the river.

The conservation of the river below London is also in some measure under the government of the City Corporation, but the Trinity House has concurrent jurisdiction, and no ballast can be raised without its authority. The appointment and control of pilots, the placing and repairs of landmarks and buoys to indicate the channels, and the establishment of floating lights, are also under the superintendence of the Trinity House. Close to London Bridge there is water sufficient for vessels of 800 tons burthen, and the legislature has placed the shipping of the port and their moorings under the direction of the harbour-masters nominated by the corporation, and approved by the Trinity House. The sinuosities, currents, and shoals in the river, and its varying depth, render the navigation rather intricate. The river pilots, who are a distinct class, conduct vessels to Gravesend, where they are relieved by the sea pilots.

Navigation of the river. Down to 1800, the commerce of London and the shipping interest suffered materially from the crowded state of the river, and the difficulties, delays, and abuses, connected with the berthing and mooring of vessels, and the landing and storing of merchandise. These evils led to the construction of the West India Docks, which were opened in August 1802.

West India docks. These, next to the Commercial Docks, the oldest in London, were formed in the gorge of the Isle of Dogs, on the Middlesex side of the river. They comprise an import and an export dock (communicating with the river at Blackwall and Limehouse), and a dock of nineteen acres for bonded timber.

The export dock, occupies about twenty-five, and the import dock thirty acres. The gates are forty-five feet wide, and admit vessels of 1200 tons. At the highest spring-tides the water is 24 feet deep; and within the docks there is sufficient space for 600 vessels of from 250 to 600 tons. The import and export docks are parallel to each other, but divided by stacks of warehouses. There are sheds for sheltering the goods; and the chief warehouses are capable of storing 170,000 hhds. of sugar, besides coffee and other tropical productions. The whole space occupied by these docks and warehouses is 295 acres.

The East India Docks at Blackwall now belong to, and East India are managed by the same company as the West India docks. Docks. They were commenced in 1803, finished in 1806, and were intended to accommodate the trade of the East India Company. They include an import basin of eighteen acres, an export basin of about nine, and an entrance basin of 2½ acres. The entrance lock is 210 feet wide, the width of the gates 48 feet, and the depth of water in the docks is never less than 23 feet. The extent of warehouse-room at these docks is comparatively small. The East and West India Docks are well inclosed and guarded, and the buildings are fireproof.

The London Docks, situate between Ratcliff Highway London and the Thames, were begun in June 1802, and opened in January 1805. They consist of two docks; the western covering twenty acres, and the eastern about seven acres. The latter is entered from Shadwell, and the former near Wapping Old Stairs, and also at the Hermitage. The whole can receive 500 vessels of from 200 to 800 tons. The entire space inclosed is seventy-one acres. The warehouses are very fine; the most extraordinary being that for bonded tobacco. The roof and pillars supporting it are of iron, and the whole building covers five acres of land, and is capable of containing 24,000 hhds.

The company is governed by a body of directors, of whom the lord mayor is one. The regulations to prevent fire and pilfering are as effectual as in the East and West India Docks.

St Katharine's Docks, situate between the London St Katharine's Docks and the Tower, were executed in a year and a half, and first opened in October 1828. The whole extent of the property is twenty-four acres, of which nearly one-half is included in the two docks, communicating by a basin. The entrance lock, near Irongate Wharf, is 180 feet long, and 45 feet broad, and admits ships of from 200 to 800 tons. The warehouses are very large and commodious, and the regulations and charges are similar to those of the other docks.

Victoria Docks, the last constructed, were completed in 1855. They are situate in the Plaistow Marshes, immediately below the East and West India Docks. The portion of this property appropriated by the Dock Company for their own purposes is about 200 acres, but the dock itself occupies but seventy-four, and affords 23½ feet depth of water. The entrance lock at Bow Creek is 300 feet long, and 80 wide. There is a half-tide basin of sixteen acres; and the available warehouse floor is stated to be upwards of eleven acres. The company have also acquired about an acre and a half between Thames Street and the river for the erection of an up-town warehouse. One object of the company is to withdraw from the Thames a portion of the large fleet of colliers which lie at anchor in the Pool, and seriously obstruct the traffic on the river.

On the other bank of the Thames, extending along the side of the river opposite Limehouse, and terminating nearly opposite the entrance to the West India Docks, are the Commercial, formerly the Greenland Docks, which existed in the seventeenth century. They are now of great extent, inclosing 120 acres, of which seventy are water, and were designed to receive vessels laden with timber, corn, and

London. other commodities more bulky than costly. These docks are entered by a basin near Dog-and-Duck Stairs, sometimes called the East Country Docks, and the main body of the water within is divided into six unequal parts.

Parallel to these is the Surrey Canal, having an inner and outer dock at its entrance in Rotherhithe, by which ships are received, and affording communication with the Croydon Canal.

The Regent's Canal was formed to save expense of cartage through London of articles brought by sea, and afterwards forwarded for consumption to the N.W. parts of the metropolis; and also to communicate with the Grand Junction Canal. The Regent's Canal passes from Paddington by a tunnel under Maida Hill to the Regent's Park, thence to Islington, under which it is carried by a tunnel three-quarters of a mile in length, and so on to Hoxton, Hackney, and Limehouse. It is 9 miles long, and is provided with twelve large locks.

It is not easy, within a moderate compass, to give even a sketch of the foreign commerce of London. It would be an epitome of that of the world. To the British capital are brought the products, natural and artificial, of all soils and all climates. It has in store whatever the ingenuity and industry of man in any part of the globe can spare to exchange for what his own country does not yield. We can, therefore, do little more than state the number and size of the vessels that belong to and frequent the port, and the value of the produce and manufactures of the United Kingdom exported from the same.

Account of the Number and Tonnage of Vessels belonging to the Port of London on 31st December 1855.

Description of Vessels.	Under 50 Tons.		Above 50 Tons.	
	Vessels.	Tons.	Vessels.	Tons.

Total	19,026	2,850,317	14	1,906

The conveyance of coals to London employs a great deal of shipping. They are chiefly brought from the north-eastern district of the kingdom, and are sold at the New Coal Exchange, lately erected in Lower Thames Street.

Account of the Number of Ships laden with Coal which entered the Port of London in each Year from 1845 to 1855 inclusive.

Years.	Ships.	Years.	Ships.	Years.	Ships.
1845	11,987	1849	12,074	1853	12,111
1846	10,488	1850	12,633	1854	11,857
1847	11,911	1851	11,765	1855	10,734
1848	12,267	1852	12,035		

Very large quantities of coals now reach London by means of the railways which centre in the metropolis.

Declared Value of British and Irish Produce and Manufactures exported from London to Foreign Countries and the Colonies in 1855 and 1856.

1855	L.20,915,512
1856	25,966,033

The commercial institutions of London are well adapted for business by their localities and regulations. The first object of importance to every ship, on its arrival in port, is the custom-house.

The present custom-house, opened in May 1817, stands in Lower Thames Street, with its principal and imposing front, 480 feet long, towards the river, and occupies the site of a similar but smaller one destroyed by fire in 1814, as a preceding one had been in 1718.

The long room is a noble apartment, 186 feet long, 60 broad, and of an appropriate height, with desks on each side for the several officers; the centre being left for such of the public as have business there. The other parts are distributed so as to suit the several branches of the office. The London customs establishment of clerks, tide-waiters, &c., amounted in 1856 to 2167; though, as but 1620 were required for all the other English ports, it would seem as if the numbers here were excessive.

Amount of Customs Duties collected in the Port of London in 1855 and 1856.

1855	L.11,625,125
1856	12,287,519

The Society of the Trinity House has its chief establishment in a large and handsome house on Tower Hill, built by Wyatt in 1793. It was incorporated in 1815; but from the terms of its charter, it evidently had a previous existence, and was then established at Deptford Strond. Its privileges were confirmed by the charter of 1658, and its members are now partly men of high rank, and partly those remarkable for naval knowledge and skill in maritime affairs. Its duties as to pilots, lighthouses, buoys, ballast, &c., have already been mentioned. In process of time this society acquired large property; the net revenue under its management having, in 1855, amounted to L.204,195. Until the passing of the act 13th and 17th Vic. c. 131, the society spent much of its surplus revenue in pensions to poor and disabled seamen or their widows and orphans; but this act transfers their revenue, as well as the charge for maintaining lighthouses, &c., to the Mercantile Marine Fund. It would appear, from a parliamentary paper lately published, that the Board of Trade expended in 1856 out of this fund L.1388 as rewards for the salvage of life.

The Trinity House contains some portraits of naval heroes, naval trophies, &c.

The Royal Mint, also on Tower Hill, was removed thither from the Tower in 1811. The present building, which is extensive and well suited to its purpose, was completed under the direction of Sir R. Smirke. The interior is appropriately arranged for the manufacture of coin; and the machinery combines great ingenuity and beauty. In consequence of the report of a commission in 1849, the old company of moneyers was abolished, and a scientific chief has since been allotted to this department, instead of a political one.

The amount of gold, silver, and copper money coined here in the last three years has been as follows:—

Account of the Total Value of Gold, Silver, and Copper coined at the Mint in each of the Three Years ending with 1856.

Year.	Gold.	Silver.	Copper.	Total.
1854	L.4,152,183	L.140,480	L.60,866	L.4,353,529

London.
Bank of
England.

The Bank of England, one of the most attractive objects in the city, was founded by act of parliament in 1694, and its business was carried on for many years at Grocers' Hall. In 1733 it was transferred to Threadneedle Street, and soon thereafter the present hall and bullion office were opened. Between 1770 and 1788 the façade was extended, and two wings added, under the directions of Sir Robert Taylor and Sir John Soane. Under the superintendence of the latter, the front and wings of the original structure were harmonized. The area of the bank is an irregular quadrangle; the south or principal front is 365 feet, and the north 410; the east 245 feet, and the west 440. Its principal entrance is from Threadneedle Street, the other two from Bartholomew Lane and Lothbury. The interior contains several open courts, the rotunda, or circular room, numerous offices, committee-rooms, and private apartments for the residence of officers and servants. The business is carried on by a staff of about 800 clerks, &c., whose salaries amount to nearly £200,000. The bank has received nine successive renewals of its charter since it was first granted in 1694, and measures have been taken in parliament this session (the first of 1857) for again renewing it.

The act of 1844, still in force, separated the Bank into two distinct branches, viz.,—1. The Issue Department, devoted to its business as agent of the state in creating and issuing paper money, or bank-notes, convertible into gold on demand; and, 2. The Banking Department, where the private business of deposit and discount is carried on. (For an account of the Bank of England, see PAPER MONEY.)

Banks.

There are sixty private and twenty-eight joint-stock banks in the metropolis. Some few of the former, such as Child's, in Fleet Street, were established before the end of the seventeenth century; while the joint-stock banks are all the offspring of the last few years. There is an establishment near Lombard Street called the Clearing House, where a daily exchange of cheques or drafts on city bankers is effected, and this process tends greatly to facilitate banking business.

Royal Ex-
change.

The Royal Exchange, colossal in proportions, and occupying a commanding position between the Bank of England and Cornhill, is a spot where great mercantile transactions are daily concluded. The first exchange was built by Sir Thomas Gresham, completed in 1567, but destroyed by the great fire of 1666. It was, however, speedily rebuilt, and was opened on 28th September 1669. Again destroyed by fire in 1838, it was rebuilt, and completed in 1846 by Mr Tite. The present building is quadrangular, and the interior surrounded by arcades. In the centre, which is uncovered and unprotected from the weather, stands a statue of Her Majesty by Lough. The outside of the building, except the grand western entrance, is occupied by small shops; and on the upper floor is Lloyd's, where the business of marine insurance is conducted by underwriters. It has been estimated that, on an average, 200,000 persons daily visit the exchange, but this can be little more than conjecture. Merchants and brokers resort much to coffee-houses in the vicinity of the Exchange for the transaction of business.

Most of the larger transactions are negotiated by brokers, who in general confine themselves to one branch of trade, with which they are thoroughly acquainted. Thus we have colonial brokers, insurance brokers, ship brokers, stock brokers, bill or money brokers, &c.

Stock Ex-
change.

Near the Royal Exchange and the Bank is the Stock Exchange, where real and fictitious sales are made of property in the public funds, &c.; the latter for the most part being a species of gambling.

Manufac-
tures.

London, when compared with some of the towns in the north and west of England, can scarcely be called a manufacturing place; yet the various articles produced here employ many thousand persons. The silk manufacture especially

employs a large number of hands. Originally introduced by French Protestant refugees, many of their descendants still continue the trade, which employed, in 1851, 15,764 persons, of whom 8277 were females.

London.

The manufacture of London porter and beer is a much more lucrative business, but a London brewery requires a very large capital. Sugar-refining and clock and watch making also prevail to a considerable extent, the latter chiefly in a district called Clerkenwell. London-built carriages are generally considered the best, as they are undoubtedly the most elegant in the world. London enjoys a high reputation for the manufacture of numerous smaller articles, such as mathematical, surgical, and musical instruments, jewellery of the superior kinds, gold and silver plate, &c.

The great number of those employed in house-building proves that the metropolis is still rapidly extending; and though this business received a severe check during the late war with Russia, it was only temporary, as evinced by the general resumption of building in the various outskirts of London.

The shops in London are, generally speaking, well managed, and many of them are handsomely fitted up, especially those in Bond Street, Regent Street, and Oxford Street. The wholesale shops or warehouses are chiefly to be found in the city; the retail shops, particularly those on a large scale, being more general in the west or fashionable end of the metropolis. The bazaars in London, each of which forms an aggregation of shops or stalls, are not now so attractive as they once were. They deal mostly in fancy goods, furniture, toys, &c. The four great establishments of the kind are those in Soho Square and Baker Street, the Pantheon in Oxford Street, and the Pantechnicon in Halkin Street, Belgrave Square. The Burlington and Lowther Arcades contain many shops for the sale of the like commodities.

Table showing the Area in square miles, and the Population, of the Metropolis, the Number of Houses therein, and the Number of Families occupying the same in 1851.

Divisions.	Area in square Miles.	Houses.			Families, or separate occupiers of dwellings.	Population.
		Inhabited.	Uninhabited.	Build- ing.		
Part in Middlesex	61	213,279	10,613	3,046	395,703	1,745,601
Part in Surrey...	36	72,314	4,524	1,160	110,027	482,435
Part in Kent ...	35	20,310	1,506	609	27,850	134,202
Total.....	122	305,933	16,643	4,815	533,580	2,362,238

Account showing the Number of Persons over 20 years of age in the Metropolis in 1851, distinguishing the Married from the Unmarried.

Sexes.	Of the age of 20 Years and Upwards.			
	Total.	Bachelors and Spinsters.	Husbands and Wives.	Widowers and Widows.
Males	632,545	196,857	398,624	37,064
Females	762,418	246,124	406,266	110,028

In 1851 there were, as above stated, 305,933 inhabited houses in London. These for the most part are built of brick, though many of the private houses externally, such as those of the Duke of Sutherland, Lords Ellesmere and Spencer in the Green Park; the Duke of Wellington in Piccadilly, Lord Lansdowne in Berkeley Square, and Mr Holford in Park Lane, are either built of or faced with stone. But it is now very much the practice to cover the

Houses in
London.

London. brick fronts of houses with plaster or cement in imitation of stone; and though fastidious critics object to the fictitious character thus imparted to them, there can be no doubt that its effect is very good. Admirable specimens of this work may be seen in the magnificent façade of Carlton Gardens towards St James's Park, in Belgrave Square, Albert and Prince's Gates, Hyde Park, &c.

The upper class live principally in that part of London west of Regent Street, consisting chiefly of St James's, Berkeley, Hanover, Cavendish, Portman, Grosvenor, Belgrave, and Eaton Squares, and Park Lane, with the clusters of streets around them. This class, composed in great part of members of the legislature and their families and connections, and forming as a whole what is called the fashionable world, are resident in London for but the smaller portion of the year. Arriving in time for the beginning of the parliamentary session in February, they desert London at its termination in the end of July.

The middle class are scattered over all parts of the metropolis: their business being carried on for the most part in the districts east of Regent Street, they become migratory in the afternoon, some seeking the suburbs, and others living in the squares, terraces, and streets in such districts as Pimlico, Brompton, Bayswater, Portland Town, Camden Town, Holloway, Hackney, Peckham, Camberwell, Brixton, Clapham, &c. In the domestic arrangements of this class, speaking generally, the chief object is comfort; and this is the prevailing characteristic in the dwellings of merchants, tradesmen, and professional men of the metropolis.

The abodes of the poorer classes descend very rapidly in the scale from comparative comfort to downright misery. The skilled operative may manage to have a house of his own, but the more ordinary operative or the labourer must content himself with a lodging. These classes are pent up for the most part in such districts as Whitechapel, Bethnal Green, Southwark, Lambeth, Westminster, Chelsea, Paddington, Marylebone, St Giles, &c. It appears, from Mr Glover's *Report on the Lodging-houses of London* (January 1855), that there were then 10,284 common lodging-houses, more or less under the superintendence of the police—the estimated population of the same being 82,000. These are, of course, of the very lowest description,—miserable hovels,—yet much improved under the operation of the act of 1851 for their better regulation. Several benevolent societies, such as the Metropolitan Association for Improving the Dwellings of the Industrious Classes, are struggling to introduce a better taste among the poor, by building model lodging-houses for their use; but their utmost efforts must be quite inadequate to meet the requirements of the numbers whom they wish to serve.

In the *London Post-Office Directory* for 1857 are given the addresses of no less than 387 licensed hotels and taverns, and forty-three private hotels. The great hotels, such as the Clarendon, Mivart's, &c., are situate chiefly in the west end of London; and those at the stations of the Great Western, North-Western, and Great Northern Railways, are on a gigantic scale. Comfortable commercial hotels are scattered in great abundance throughout the other parts of the metropolis; and the old-fashioned inns are disappearing fast, or adopting the improvements and conveniences of the day.

The beer and gin shops are very numerous, the proprietors of such establishments numbering, in 1851, 7891. Large numbers of the working-classes dine in the beer-shops.

Markets.

It is difficult to form even a conjectural estimate of the consumption of each description of food in London. But calculating that, on the average, 3d. per diem for food be expended for each of the two and a half millions of inhabitants, the annual expenditure of its population under this head

will amount to L.11,406,250. The great provision market^s of London are ten in number, of which Mark Lane is confined to corn, the New Cattle Market at Holloway is the substitute for Smithfield Market lately suppressed, Billingsgate Market that for fish, Covent Garden that for fruit and vegetables, Leadenhall the principal one for poultry; and Newgate Market is chiefly for butchers' meat: the remaining five being of a more miscellaneous character. There are also numerous markets on a smaller scale. From these various sources the retail dealers and shopkeepers draw their supplies and distribute them to the inhabitants.

From different quarters we have gleaned the following estimates of the annual consumption of certain articles of London food. All, however, may be considered applicable to the period of the last census in 1851 :—

Wheat.....	1,600,000 quarters.
Bullocks	240,000 head.
Sheep	1,700,000 „
Calves	28,000 „
Pigs.....	35,000 „
Exclusive of large quantities of bacon and ham.	
Poultry.....	3,748,000 head.
Game, &c.....	1,807,000 „
Fish, wet and dry, of which more than half were herrings.....	
	450,180,900 lb.
Oysters.....	309,935 barrels.
Potatoes.....	310,464,000 lb.
Cabbages.....	89,672,000 „
Onions.....	1,489,600 „
Apples.....	725,500 bushels.
Foreign eggs	about 75,000,000
Milk, the produce of	13,000 cows.

Although London is supplied with many excellent springs of fresh water, they proved, centuries ago, quite inadequate to the wants of the citizens. As already mentioned, conduits were then adopted as a substitute. The first effort to supply water on a great scale was made in 1608 by Sir Hugh Myddelton,—a spirited citizen, who undertook, at his own risk, to convey a river of fresh and good water to the city. From this we may presume that in Myddelton's time the Thames no longer merited the eulogy of Stowe, that its "water was as cleere as that of the sea." In 1613 the River Lea water was let into the basin at the New River head at Islington, and thence, at the present day, the New River Company, with increased means, transmit the water through pipes to the houses, &c., supplied by them.

At present there are in all nine metropolitan water companies; but their supplies were much complained of as insufficient and unwholesome, especially during the prevalence of cholera in 1832, 1849, and 1854. Remedies have, as will be seen from the annexed table, been applied to the first of these evils, and there is now abundance for domestic purposes, besides a sufficient quantity from the street plugs for flushing the sewers regularly, and supplying the engines in cases of fire.

Thus, while 270,581 houses were daily supplied in 1850 with 44,383,332 gallons, it will be seen by the annexed statement that no less than 81,025,842 gallons were daily furnished in 1856 to 328,561 houses, leaving only about 12,000 houses unprovided by the water companies, within the bills of mortality. Great progress has also of late been made in providing a purer supply.

In consequence of the act of 1852, all water now drawn from the Thames for human consumption is taken at some point beyond the influence of the tidal wave, and so untainted by the impurities of London sewers. The result of a series of analyses of the water supplied by the various companies previous and subsequent to 1852, has been published by the Board of Health. From it we gather that the organic matter now contained in the water is comparatively trifling.

The establishment of public baths and wash-houses in various parts of the metropolis is an important improvement of recent date.

London.

London. Table showing the Extent of the Metropolis Water Supply in 1856, taken from Parliamentary Returns, prepared by the Board of Health.

List of Metropolis Water Companies.	Sources of Supply.	No. of Houses supplied	Gross Quantity supplied per Day.	Length of Mains and Branches.
			Gallons.	Miles.
New River....	River Lea, Chalk Springs, &c...	95,083	25,000,000	400 to 500 say 450
East London...	River Lea.....	70,000	16,000,000	331
Southwark & Vauxhall...	River Thames, at Hampton.....	41,529	10,331,122	432
Lambeth.....	River Thames, at Thames Ditton	28,541	6,109,000	206
West Middlesex	River Thames, at Hampton.....	25,732	6,895,368	178
Chelsea.....	River Thames, at Seething Wells.....	25,030	5,323,000	198½
Grand Junction.....	River Thames, at Hampton...	17,221	6,714,292	117
Kent	River Ravensbourne.....	16,077	3,500,000	124
Hampstead....	Ponds and Chalk Well	6,348	603,060	33½
Plumstead & Woolwich...	Chalk Well.	3,000	550,000	16
	Totals....	328,561	81,025,842	2,086

The average daily supply which, in 1854, was 164 gallons per house, amounted in 1856 to 246 gallons. The annual supply in the latter year would therefore exceed 29,574,432,000 gallons.

The liquid in London next in importance to water is porter or beer,—a malt liquor of great repute, and looked upon by the major part of the middle and lower classes as a necessary of life. The breweries where this beverage is produced are the largest manufacturing establishments in the metropolis; and the capital necessary for the maintenance of one of them, with its necessary appendages, such as public-houses for the sale of the porter, drays, horses, &c., is enormous. To give some notion of the extent to which this business is carried, we subjoin a table (the materials for which are borrowed from M'Culloch's *Commercial Dictionary*), showing the quantity of malt brewed in 1852 by each of the fourteen largest houses in London:—

	Quarters.		Quarters.
Barclay and Co.	112,494	Hoare and Co.	33,769
Truman, Hanbury, and Co.	124,416	Calvert and Co.	32,310
Meux and Co.	66,296	Mann and Co.	30,881
Reid and Co.	60,100	Charrington and Co. ..	26,366
Whitbread and Co. ...	53,236	Taylor and Co.	17,660
Combe and Co.	47,304	Goding and Co.	16,959
Elliott and Co.	36,222	Courage and Co.	16,014

The fuel used in London is almost exclusively coal. Annexed is an account of the quantities brought into London in 1851 and 1852, distinguishing the quantities sea-borne from those conveyed by railways and canals:—

	Coastwise.	Inland Navigation and Land Carriage.	Total.
1851.....	3,236,542 tons	254,421 tons.	3,490,963 tons.
1852.....	3,330,428 ...	414,917 ...	3,745,345 ...

Of course the consumption is materially affected by the severity or moderation of the winter season.

The general introduction of gas about 1820 wrought quite a revolution in the lighting of London; and unquestionably this city, as a whole, is better lighted than any other metropolis. There are in all sixteen gas companies, which share among them the business of supplying light of this kind to the street lamps, shops, and houses of the metropolis; and the estimated annual consumption in that way is about 6,000,000,000 or 7,000,000,000 cubic feet. It would be impossible to make any similar calculation with

London. regard to the consumption of candles, oil, &c. It may be added, that the use of gas in London for domestic purposes is not by any means universal, on account of its greater impurity here than in such places as Liverpool and Edinburgh.

Perhaps nothing proves more decidedly that the prudential principle is strong among the middle and lower classes of London than their extensive use of savings banks. The annexed table shows the number of depositors in the metropolitan establishments of this kind, and the amount of their deposits in 1854.

Number of Depositors in London Savings Banks on 20th November 1854.

In Savings Banks in—	Number of Open Accounts.	Total Amount due to Depositors.
		£ s. d.
Part of Metropolis in Middlesex	226,128	4,997,150 11 1
Do. do. Surrey.....	27,083	539,325 10 2
Do. do. Kent.....	5,883	160,704 1 2
Total	259,094	5,697,180 2 5

The first life insurance society in England was established here in 1766; and there are now (1857) no less than 225 insurance offices in London, of which upwards of 200 undertake the insurance of life. But it is not to be supposed that all these offices are equally trustworthy. The number of new offices that are projected every year, and the number that regularly expire within a similar period is convincing evidence that this business, if not overdone, is mismanaged, or tampered with to a considerable extent.

Remarkable as London is for its wealth, it has a large pauper population, necessarily a burden on their richer brethren. It will be seen by the following table that no less than 77,963 persons were in the various poor-law unions and other workhouses in the metropolis during the year ended 25th March 1856.

Table showing the Number of Paupers admitted into the Poor Law Union and other Workhouses of the Metropolis in the Year ended 25th March 1856, and the Number receiving Medical Treatment therein, and the Mortality during the same period.

Union Workhouses.	Number of Paupers admitted.	Number under Medical Treatment.	Deaths.
Part in Middlesex exclusive of St Pancras Parish*	61,768	31,075	3689
Surrey.....	14,428	5,084	1101

Total	77,963	37,693	5253

* No return made to Parliament by this parish.

The amounts received from poor-rates in the metropolis, and expended for the relief of the poor, in the years 1855 and 1856, were as follows:—

	1855.	1856.
Total amounts received from poor-rates.....	L.1,250,737	L.1,360,464
... expended for relief of poor.....	841,302	875,264

From other sources, such as alms-houses, soup-kitchens, and the miscellaneous charities with which London abounds, many poor people derive the means of existence, either wholly or partially; and an army of street beggars, of whom the majority are impostors, trade too successfully on the credulity of the benevolent. The Mendicity Society has done good service in exposing and punishing many of these cheats, but their business is too profitable to be easily surrendered.

London.
Criminals.

Taken as a body, the people of this great city are remarkable for their love of order; yet the amount of demoralization and crime is very large, though perhaps not out of proportion to the population and the temptation that exists in such a place to breach of the law. It is stated in the population tables for 1851, that there are in London upwards of 13,000 males and 18,000 females who have no stated occupation or ostensible means of existence, or, in other words, who live by malpractices. And the annexed account, applicable to 1856, will throw some light on the nature and probable frequency of the crimes and misdemeanours that are most prevalent among them:—

Nature of Offences.	Annual number taken into custody by the Metropolitan Police.*	Annual number summarily convicted or held to bail by Police Magistrates.	Annual number convicted and sentenced by Superior Courts.
Offences against the person ...	10,489	6,314	162
Offences against property, with violence.....	398	...	307
Offences against property, without violence	20,345	8,659	1856
Malicious offences against property	2,686	1,742	6
Forgery and offences against the currency	1,319	...	237
Other offences	38,003	16,736	19
Total	73,240	33,451	2587

* This account does not include offences committed within the city.

* Number of sittings not returned for thirty-five places of worship.

† Number of attendants not returned for fifty-three places of worship.

There are numerous societies in London for the promotion of religious knowledge and morality. The chief of these are,—the Society for Promoting Christian Knowledge, founded 1698; the British and Foreign Bible Society, established in 1804, and encouraged by all religious denominations; the Society for Propagating the Gospel in Foreign Parts, established in 1701; the Religious Tract Society, instituted in 1799; the London Missionary Society, and the Church Missionary Society,—the former commencing its labours in 1795, and the latter in 1799.

Table showing the Number of Sunday Schools in the Metropolis in 1851, and the Number of Scholars attending the same; distinguishing the Religious Denominations under which they are maintained.

Of the 73,240 persons taken into custody in 1856, 45,941 were males, and 27,299 females. Out of these large numbers but 375 males and 6 females are distinguished as having received superior instruction, while 8332 males and 7150 females could neither read nor write. Another portion, viz., 33,946 males and 19,594 females, either could read and were unable to write, or could read and write but imperfectly. The remaining 3288 males and 549 females were capable of reading and writing with facility. Among the 2587 who were convicted and sentenced by the superior courts, only 15 were found to belong to the better educated class. Thus, we may safely infer that a liberal extension of education to the poorer classes will operate in an inverse ratio on crime, and prove to some extent an economical measure. In farther confirmation of this conclusion, we may refer to the good already resulting from the establishment of metropolitan ragged schools, for those attending them are chiefly drawn from the class whose occupations go so far to swell the list of crimes and misdemeanours.

The number of churches in London has increased rapidly within the present century. Thus we find that the Church Building Commission had, in the interval between its formation in 1818 and 1856, when it merged in the Ecclesiastical Commission, built wholly or partly no less than 123 in the metropolis, and private endowments have been numerous within the same interval. Yet it will be seen by the annexed table, that for the population of London, 2,362,236 in 1851, there were at that time sittings (including places of worship of every kind) for but 700,000 or thereby.

Religious worship and instruction.

The education of the people has at length assumed its proper importance in the eyes of the public, and a minister of education has this year (1857) for the first time taken his seat in the House of Commons. It will be seen by the annexed table that there are in London 863 public and 3698 private day schools, exclusive of Sunday schools:—

Table showing the Number of Day Schools in the Metropolis and attendant Scholars therein in 1851, distinguishing Private from Public Schools, and the means by which the latter are supported.

Description of Schools.	Number of Schools.	Number of Scholars.		
		Males.	Females.	Total.

Private day schools.....	3698	43,198	43,743	86,941
Total day schools.....	4561	140,873	113,366	254,239

London.

Yet the cost of education here is heavy, and a great many schools are but indifferently conducted. It would, however, be preposterous to attempt here any general description of those establishments, and it will suffice to allude shortly to those institutions connected with education which are of the highest degree, or that boast of great antiquity, wealth, or usefulness.

The University of London, established in 1836, consists of a body of government examiners, empowered, after due examination, to grant degrees in arts, law, and medicine, to the graduates of University and King's Colleges in London, and to several other proprietary establishments of a similar kind. The senate consists of upwards of thirty members, having a chancellor and vice-chancellor, and the business of the board, and the examinations at stated periods, are conducted in Burlington House, Piccadilly.

Schools of anatomy were first instituted in the metropolis about 1720, and now medical and surgical schools are attached to all the great London hospitals. Lectures are delivered during the winter by men distinguished in the profession, and the extensive and varied practice of the hospitals is thus combined with theoretical study. Examinations for licenses or diplomas to practise medicine are conducted by the College of Physicians in Pall Mall, and similar examinations with regard to surgery take place in the College of Surgeons in Lincoln's Inn Fields.

In May 1855, by order in council, a government commission was established for testing the fitness of candidates for situations in public offices. The office is in Deans Yard, Westminster.

University College, in Gower Street, opened in 1828, is an extensive, well-arranged, and handsome edifice. It is frequented by students of law, medicine, ancient and modern languages, &c. This college is open to all religious persuasions.

King's College, Somerset House, opened in 1831, is, like the rival institution last mentioned, a proprietary establishment, but is peculiarly attached to the Church of England, and instruction in religion here forms part of the course of education, which in other respects resembles that afforded in University College.

St Paul's School, St Paul's Churchyard, founded by Dean Colet in 1509, for the gratuitous instruction of 153 boys, was rebuilt in its present classic form, in 1823. The Mercers Company are the trustees of the institution and have the presentations. John Milton, and John, Duke of Marlborough were educated here.

Christ's Hospital (or the Blue-coat School), originally the house of the Grey Friars, founded in 1226, was turned to its present use in 1552, when, according to Stow, "after the erection of Christ's Hospital in the late dissolved house of the Grey Friars, a great number of poor children being taken in, a school was also ordained there, at the citizens' charge." (Stow, ed. 1633, p. 64.) Edward VI. in the same year granted the hospital a charter, and Charles II. attached a mathematical school, charging the exchequer with L.1000 per annum for its support. The governing body consists of the aldermen of London, governors *ex officio*, and contributors of L.500 each (formerly L.400) to the hospital funds, numbering in all, at present (1857), 512. The aldermen of the city have each an annual nomination, and the other governors have presentations as vacancies occur. Most of the children admitted are those of freemen of London, or of clergymen of the Established Church; and it has long since ceased to be what its founders intended—a charitable institution. A branch school is maintained at Hertford for younger children, including 70 girls; and the total average number constantly maintained and educated by the hospital in 1855 and 1856 was 1240, viz., 860 in the London establishment, and 470 at Hertford. They are well fed and taken care of, and warmly though fantastically

London.

clothed in the costume of the time of Edward VI. The buildings are old and irregular, except the great hall, completed in 1829, and which, fronting the opening lately made in Newgate Street, is one of the chief ornaments of the city. The revenue and expenditure are generally about equal; the former in 1855 being L.58,075, 17s., and the latter L.58,547, 4s. 6d. Camden the historian and Richardson the novelist were educated here.

St Peter's College, Westminster (better known as Westminster School), attached to the collegiate church of that name, or Westminster Abbey, was founded by Queen Elizabeth in 1560, for forty foundation or queen's scholars. Though originally a free school, it no longer bears that character, as the cost of education, board, and lodging paid for each of the queen's scholars is about L.45 a-year. Besides the master, usher, and scholars on the foundation, there are five other masters, two ushers, and many scholars, the latter varying in number from time to time. The queen's scholars are selected from the whole school for proficiency in studies. Eight of the queen's scholars are chosen after each examination, four of whom are sent to Trinity College, Cambridge, and four to Christ Church, Oxford. Ben Jonson, Dryden, Locke, and Gibbon were educated here.

Merchant Tailors' School, "one notable free grammar school," as Stow calls it, was founded in 1561 by the Company of Merchant Tailors. The first school perished in the great fire of 1666, and the present one was erected in 1675 on the same site in Suffolk Lane, Cannon Street. It is built of brick, and supported on the east by stone pillars, forming a cloister. The number of scholars is limited to 250, and presentations are in the gift of the members of the court of "Merchant Tailors" in rotation. After the annual examination, some of the scholars are invariably sent to the university; this school being endowed with 35 fellowships, 6 civil law, and 2 unrestricted exhibitions in St John's College, Oxford, 6 exhibitions to any college in Cambridge, and 4 exhibitions to either university. These 53 pieces of university preferment, besides smaller exhibitions, are invariably given to pupils educated at this school.

Gresham College, in Basinghall Street, rebuilt 1843, was founded by Sir Thomas Gresham in 1581, for lectures on divinity, civil law, &c., to be read gratis, at noon in Latin, and at 1 o'clock in English, during the term. The lectures on music and geometry are now delivered in the evening at 7 o'clock. This institution is not practically very useful.

The Charter House (corrupted from *Chartreux*) is situated in a square of the same name near Smithfield. Originally a house for Carthusian monks, founded by Sir Walter Manny, *temp.* Edward III., it shared the fate of other religious houses, *temp.* Henry VIII. After passing through several hands, it was at length bought in 1611 by Thomas Sutton, who converted his purchase into a school and an hospital for decayed gentlemen. The governors are 18 in number; the queen, her consort, and eldest son, gracing the list. At present (1857) this charity supports 44 scholars, and 80 decayed gentlemen. The Charter House has long held a high character as a classical school; and besides the boys on the foundation, there are numerous scholars receiving instruction here. Of those educated on the foundation, many receive exhibitions at either university; and the hospital, in its patronage of nine livings, gives the preference to those educated within its walls. Dr Barrow, Addison, Steele, Blackstone, John Wesley, and various other distinguished men, were Carthusians.

There are seven public parks in the metropolis, viz., Hyde Park, St James's, the Green, Regent's, and Victoria Parks. Parks on the Middlesex side, and Battersea and Kennington Parks on the Surrey side of the Thames. The oldest, largest, and most beautiful, are those in the west end of London.

London.

Hyde Park is entered from Piccadilly by a series of triumphal gates, and from Oxford Street by a marble arch, removed thither from Buckingham Palace. This park, of about 400 acres, is well wooded, judiciously intersected by walks and carriage roads, and ornamented by a piece of water called the Serpentine. During the season the long ride called Rotten Row is thronged in the afternoon by equestrians of both sexes. On the south side of the park, opposite Rutland and Prince's gates, stood the Crystal Palace of 1851. Adjoining this park, are Kensington Gardens, attached to Kensington Palace.

The Green Park, next to Hyde Park, is entered from Piccadilly by a triumphal arch, bearing an equestrian statue of the Duke of Wellington. The inner road that skirts this park is called Constitution Hill, and leads to Buckingham Palace, &c. This park is small, but very pretty, and the available space was extended in 1856 by the removal of the reservoir of the Chelsea water-works. St James's Park, first inclosed by Henry VIII. when he built the palace of that name, formed in olden times the pleasure grounds of Whitehall Palace, and was the favourite lounge of Charles II. At present (1857) operations are going on for reducing the depth of the pond in the centre, and for throwing a bridge across it to facilitate the transit of foot passengers from Westminster to Pall Mall. St James's Park is laid out with great taste, and contains some very fine trees.

Regent's Park is nearly circular, and consists of 450 acres laid out in walks and shrubberies, varied by water, and intersected and skirted by carriage roads. It is nearly surrounded by houses of the larger class, built in uniform terraces, and producing a good effect. In this park are the Zoological and Botanical Gardens, and the Colosseum stands on its eastern margin. The establishment of the Zoological Society, consisting of the gardens and a large and increasing menagerie, occupies ground in the north-eastern portion of the park, and was founded in 1826. These gardens form an instructive and agreeable promenade, and were visited by 344,184 persons in 1856. The gardens of the Botanical Society, in the centre of the park, are also attractive, and are frequently used for flower shows, promenades, &c. The Colosseum, erected in 1828 by Burton, is a sixteen-faced polygon, surmounted by a dome 120 feet in diameter, and presents in front a Doric portico of six columns. It has been used for panoramas, &c.; but the attractions of the place have long been on the wane.

Victoria Park, the eastern lung of London, consists of 290 acres, lying between Hackney Common and Duckett's Canal. It was formed under Act 14th and 15th Vict., c. 46., for the benefit of the crowded districts in its vicinity.

Kennington Park, formerly Kennington Common, belongs to the duchy of Lancaster, and was inclosed and laid out as a public park for pedestrians in 1852. It contains about 20 acres, and though yet in its infancy, forms a great boon to the inhabitants of Kennington, Vauxhall, &c.

Battersea Park, on the Surrey bank of the river, opposite Chelsea Hospital, Cheyne Walk, &c., is still incomplete; but as the new suspension-bridge leading to it will be opened this year (1857), it is presumed that the park will soon be finished. 320 acres of land were purchased for this park, but only 200 acres come within the park fence, the rest being allotted to houses, roads, &c. The grounds have been laid out, and are open to visitors; and an esplanade along the whole of its river front has been formed.

Palaces.

There is no palace in London of which, as an architectural work, the inhabitants have any reason to be proud.

Buckingham-

ham palace.

Buckingham Palace, however, from its cost and magnitude, and as the only town residence of the sovereign, commands attention. It stands on the site of Buckingham House, built by John Sheffield, Duke of Buckingham, on that of old Arlington House. This property was purchased by George III., and settled on his consort; and here all

London.

their children were born except George IV. In the reign of the latter monarch, a new palace was commenced by Mr Nash, but was not finished till near the end of the following reign, and was never occupied by William IV. The body of the palace now forms a parallelogram, containing an inner court; a fourth side, or grand front, looking towards the Horse Guards, having been added during the present reign. A still later addition of ball-room, &c., has been made on the south side; and, when the Pimlico improvements have been completed, the palace will stand within its own grounds. The internal arrangements of the palace on the ground floor strike the visitor as singularly mean and unworthy of royalty; the corridors especially being dark, narrow, and low-roofed. The rooms on the first floor, including the throne-room, drawing-room, &c., are well proportioned. The picture gallery, though small, contains very choice specimens of the Dutch and Flemish schools. The grounds behind the palace are prettily laid out, and the west side of the building, which fronts them, is much admired. The cost of this palace, before the late improvements were commenced, amounted to nearly L.700,000.

St James's Palace in Pall Mall, which, among diplomatists, St James' gives its title to the English court, is a long, straggling, and dingy building, and its appearance is still what Pennant styled it, "uncreditable."

It was built by Henry VIII. on the site of an hospital for lepers, founded previous to the Conquest, and it has been extended and altered frequently since his time. His daughter Mary died in this palace; and here Charles I. slept for the last time. Charles II. and the old Pretender were both born in it; and here the two first Georges kept their mistresses. The state apartments, which look towards the park of the same name, are spacious, and used exclusively for levees and drawing-rooms. The corridors and ante-rooms, however, are rather confined. Some portions of this palace are allotted to the members of the Cambridge branch of the royal family.

Kensington Palace stands in the parish of St Margaret's, Kensington, westward of Hyde Park, and between the ton palace. Kensington and Bayswater roads. It was originally built by Sir Heneage Finch, afterwards Lord Chancellor Nottingham; and his son sold it to William III. He and his queen, Queen Anne and her consort, and George II., were all partial to this place, and all died here. Queen Victoria was born, and her uncle, the late Duke of Sussex, lived and died in this palace. It is large and irregular, built at various periods, and of red brick. The principal entrance is on the west side; but the interior presents nothing of interest. Some of the rooms have been allotted as residences to dependants of the court; and a portion of the grounds to the west of the palace, formerly used as a kitchen garden, was, in 1841, subdivided and leased for building purposes, and is now nearly covered with large mansions.

The gardens to the east of the palace are open to pedestrians, and are the favourite resort of the inhabitants of western London. These grounds are extensive, and present a variety of surface in wood and water that renders them particularly charming. In summer a regimental band plays here twice a-week, and on such occasions Kensington Gardens are the gayest and most frequented promenades in the metropolis.

The new Palace of Westminster (of which Sir Charles Barry is architect) occupies the site, on the banks of the Thames, of the old Houses of Parliament, burnt down in October 1834. The new houses were commenced in April 1840, and are (1857) not yet finished. The palace, not having antiquity on its side, and having proved costly beyond all expectation, is perhaps more severely criticised than it otherwise would have been. But it has some defects which are too obvious to escape notice. The radi-

London. cal one is its want of elevation, and this is exaggerated by the length (900 feet) of the building, and the contrast formed by the gigantic height of the Great or Victoria Tower at the southern end, which is upwards of 300 feet.

On the river front, the only one completed, the richness of tracery and endless variety of minute and laboured ornament is astonishing to a close observer. Built of a Yorkshire stone, this front rests on a foundation of granite, and has a long terrace nearly on a level with high water. This, in consequence of an invasion of the Thames, is now protected and inclosed by a dwarf wall. The royal entrance to the palace is under the Victoria Tower, through an archway 65 feet high.

Westminster hall.

The most interesting entrance, through old Westminster Hall, does not properly belong to the new palace, but, from its proximity, has been easily appropriated as the main approach to both branches of the legislature. The majestic proportions of this fine structure are very imposing, and the historical associations connected with it give it additional interest. Here Sir William Wallace, Sir Thomas More, Wentworth Earl of Strafford, Charles I., and the rebel lords of 1745, were tried and condemned to death; and here Warren Hastings and Lord Melville passed through the ordeal of impeachment. This glorious relic of antiquity dates from the time of William Rufus. Walking to the upper end, and ascending the stair to the left, the visitor finds himself surrounded by statues of men eminent in the legislature of former days, such as Clarendon, Hampden, Falkland, Selden, Walpole, Chatham, Mansfield, and Fox. These are for the most part good, and all appropriate. This vestibule leads into the central or St Stephen's Hall, surmounted by a lantern tower. The hall is well proportioned, and decorated in unison with the rest of the building. Three other corridors centre in it; that to the right leading to the House of Lords, and the opposite one to the House of Commons; the third being the way to committee-rooms, offices, &c. On entering the House of Lords, the richness and profusion of the gilding and painting are apt to dazzle the eye; but perhaps this may be remedied when the whole is mellowed by lapse of time. The throne is especially gorgeous. The House of Commons is much plainer than that appropriated to the Lords.

The square clock tower, at the north end of the palace, is upwards of 300 feet high, and is all but completed. It has lately been furnished with an enormous bell, 16 tons weight, called "Big Ben," in honour of Sir Benjamin Hall, chief commissioner of works.

Lambeth palace.

Lambeth Palace, the London residence of the Archbishop of Canterbury, is situate on the Surrey bank of the Thames, almost opposite the Houses of Parliament. The property came to this see so far back as 1197, in consequence of an exchange with the see of Rochester. About 1250 great additions were made to the palace by Archbishop Boniface (of Savoy). Again, prior to 1443, Bishop Chicheley greatly improved it, and founded the Lollards' Tower, so called from its use as a prison for the early reformers of that name. Rings, to which they were chained, are still attached to the walls of a room at the top of this tower.

The palace was farther extended and improved by Archbishops Cranmer, Pole, Parker, and Laud; and Archbishops Bancroft and Abbot left all their books and MSS. to the incumbents of the see.

During the civil wars in the time of Charles I., Lambeth suffered severely, and the library was saved solely by the dexterous management of John Selden. The palace being in a ruinous state when Dr Juxon was appointed to this see after the Restoration, he did much to restore it, and added the noble apartment now used as a library. He and Archbishops Sheldon, Tenison, Secker, and Cornwallis,

made valuable additions to the collection of books, which now number from 20,000 to 25,000 volumes, with from 1200 to 1300 MSS. (See LIBRARIES.) During the incumbency of the late archbishop (Howley), important and costly additions, designed by Mr Blore, and completed in 1833, were made to the palace. The old banqueting-hall, with a fine oak roof, and the chapel, are both worthy of remark; and the palace is oak pannelled nearly throughout. Gardens of 12 acres are attached, but they are unpleasantly situated, and surrounded by houses of an inferior order. The site of the palace, too, is low, and must, from its proximity to the river, be occasionally damp and disagreeable.

Having already noticed those establishments in London, including the Custom House, which are chiefly subservient to the commercial intercourse between the metropolis and foreign countries, we proceed to mention the other public offices, &c., of most importance.

The offices of the first lord of the Treasury, the chancellor of the Exchequer, and of the secretaries of state for Foreign and Colonial affairs, are all in Downing Street, but their outward appearance would not challenge remark except of a depreciatory kind. The Privy Council Office, Board of Trade, Treasury, and Home Office, looking towards Whitehall, present on the contrary, a uniform and handsome front, erected a few years ago by Sir Charles Barry. Proceeding towards Charing Cross, the Horse Guards is the next building of note, and includes the offices of the Commander-in-chief, adjutant-general, quarter-master-general, &c. Behind it, in St James's Park, is the parade-ground for the guards. Then comes the Paymaster-general's office, not at all remarkable in an architectural point of view, and next to it the chief branch of the Admiralty, forming the head-quarters of the board and secretaries. The building has a lofty portico over the main entrance, with two wings projected to a screen fronting the street and inclosing a quadrangular court. The chief departments of the War Office occupy the house in Pall Mall formerly appropriated to the old ordnance department and other premises since acquired on either side.

Somerset House was erected for the most part in 1775-1782, by Sir William Chambers, on the site of a palace commenced by the Protector Somerset, and used as a royal residence by Queen Elizabeth and Charles II. It is one of the noblest features of London, contrasting most favourably in elevation and architectural and general effect with many other public buildings of the capital. It occupies a space upwards of 800 feet wide, and 300 deep, and forms three quadrangles, the central one being on a very large scale. The river front is a spacious terrace, to which a west wing, in perfect harmony with the main body, has just been added. The east end, a part of King's College, being of brick, and otherwise unlike the rest of this grand structure, slightly mars its effect as a whole. The front towards the Strand, and that just completed in Wellington Street, are of much smaller extent, but well proportioned. Somerset House is almost exclusively devoted to public offices, such as the Inland Revenue Department (employing in the metropolis alone in 1857 a staff of 900 officers), the larger branches of the Admiralty, the Audit Office, Office of the Registrar-General, &c.

The Post-Office, in St Martin's-le-Grand, is a gigantic establishment, and one whose arrangements must necessarily attract the most general attention throughout the empire. Considering the enormous extent of the national correspondence, the business of this department is conducted with wonderful correctness and celerity. The London establishment at present (1857) consists of about 590 clerks, and 2060 sorters and letter-carriers. There are also in the metropolis about 300 district and pillar post-offices.

London.

London. *Statement showing the number of Letters conveyed through the Post-Office from one district of London to another in each year from 1850 to 1855 :—*

Years.	Letters.	Years.	Letters.
1850.....	38,887,844	1853.....	42,816,314
1851.....	40,585,952	1854.....	46,191,569
1852.....	40,403,207	1855.....	45,844,963

The gross post-office revenue of the kingdom in 1855 amounted to L.2,716,420, and the net revenue to L.905,150.

Various plans for concentrating the majority of the great offices in Whitehall have been lately under consideration, and parliament has taken one step towards approving such a scheme by voting a sum for erecting a new foreign office.

East India House.

The East India House, in Leadenhall Street, was erected in 1726, but has been greatly enlarged. Its principal front, towards Leadenhall Street, built within the last thirty years, is 200 feet in length, having in the centre a portico of six Ionic fluted pillars, supporting a frieze with allegorical figures. It contains some fine apartments, especially the great court-room. The library is rich in books, and especially in MSS., illustrative of the history and antiquities of India. The old museum is filled with Indian curiosities of every kind; and this year (1857) another museum has been constructed, exclusively for exhibiting the varied products of the British Empire in the East.

East India Company.

The East India Company was formed in 1599, and chartered by Elizabeth in 1600. Its commercial character ceased in 1835; and it is now merely a political body, governing British India under the superintendence of the Board of Control. The Board of Directors of the India Company consists partly of nominees of the crown; but is in great part made up of representatives elected by the proprietors of India stock. The revenues of India, managed by the Company, amounted, in 1854-5, to L.27,312,235, and its expenditure to L.29,019,599.

Tower of London.

The Tower of London, so full of interest to all readers of English history, was commenced by William the Conqueror in 1078; and the Great, or White Tower, and the curious Norman chapel within it, still extant, were finished by his son, William Rufus, in 1098. Since that period nine lesser towers have been added. For many centuries this fortress was used as a palace and a state prison, and contained the chief mint of the kingdom; but it is no longer used for any of these purposes. The only portions to which the public are admitted, are,—the armouries; the jewel-house, containing the regalia and coronation plate; the Beauchamp tower, in which Lady Jane Grey was confined; and St Peter's church. The collection of armour is good, and the most remarkable specimens are pointed out and described to visitors by attendant warders dressed in the costume of the yeomen of Henry VIII's guard.

There are also within the precincts of the Tower a portion of the records of the kingdom in charge of the Master of the Rolls; the military store branch of the War Office; and a barrack built on the site of the grand store-house destroyed by fire in 1841, and usually occupied by a battalion of the Foot Guards. Very pretty gardens have taken the place of the old moat, drained as a nuisance in 1843. The well-known Traitors' Gate is situate about midway in the Tower wall which faces the Thames; and near it is the Bloody Tower, which, according to history and tradition, has deservedly earned its name. The spot on Tower Hill famous for executions, is opposite the western angle or bastion of the Tower.

The chief officers attached to this ancient fortress (now a fortress only in name) are the constable, lieutenant, and deputy-lieutenant. The Duke of Wellington held the first-mentioned office for many years previous to his death, and a statue to his memory stands near the White Tower.

St Paul's.

The cathedral church of St Paul's, inferior in size, but in some points superior in design to St Peter's at Rome, stands

on Ludgate Hill, the site of old St Paul's, as well as of previous churches. Old St Paul's, built, it is supposed, in 603, temp. Ethelbert, and afterwards extended and restored at various times, suffered frequently by fire, before its final destruction, with the greater part of the city, in 1666.

The first stone of the present cathedral was laid by Sir Christopher Wren, in 1675, and it was completed by him, after his own design, in 1710. It is cruciform, classic in style, and in effect singularly grand: the centre of the cross being covered by a dome of faultless proportions. It has frequently been remarked, that the whole of this edifice was reared under one architect, by one master mason, and during the incumbency of one Bishop (Dr Compton) of London, while the erection of St Peter's, by twelve successive architects, occupied 145 years. Undoubtedly St Paul's is similar in many respects to St Peter's, but it is not at all a servile copy; and though in miniature, when compared with the Roman temple, it forms a noble monument to the genius of its architect. The height of St Paul's, from the pavement of the churchyard to the top of the cross, is 370 feet; its length, from E. to W., 510; and width, from the entrance of the north to that of the south transept, 250 feet. The circuit of the cathedral is 2292 feet, the ground it covers upwards of 2 acres, and the whole is inclosed by a dwarf wall and railing. The west end, 180 feet wide, is ornamented by twelve Corinthian, supporting eight composite columns; and the outer portion of the whole is decorated by pilasters of these two orders. The north and south entrances are uniform and semicircular, and this is the shape of the eastern end. The whole is built of Portland stone, now much discoloured by time and London smoke; but this acquired tint, dark and varied as it is, seems to accord with the solemn dignity and grandeur of the church.

The interior of the cathedral is worthy of the exterior, and presents its most imposing aspect to a visitor entering from the west, and so approaching the choir. When the centre of the transept is reached for the first time, and he stands under the dome, feelings of wonder and delight cannot be restrained. The height and span of the dome convey at a glance the idea that this must be the sublime in architecture.

The simple grandeur of the interior is, perhaps, somewhat marred by the presence of monuments in a style of art scarcely worthy of such a place. The most important of them are those to Dr Johnson, and Howard the philanthropist; Lords Nelson and Howe; Sir Ralph Abercromby, Lords Rodney, Collingwood, Cornwallis, and Heathfield; Generals Moore and Picton, &c. The most appropriate monument is that over the entrance to the choir. It is a marble slab in honour of Wren himself, bearing an inscription ending with the words,—"*Si monumentum requiris circumspice.*"

The choir in which the service is daily performed contains a great deal of carved wood by Gibbons, and is furnished with an organ of powerful and fine tone.

In the crypt are the tombs of Nelson and Wellington.

By an inside staircase the visitor may reach a circular gallery within the dome, called, from an effect in acoustics produced by its shape, the "Whispering Gallery." The paintings by Sir James Thornhill, in the interior of the dome, illustrative of the life of St Paul, and cleaned and restored in 1856, may here be seen to advantage.

From hence the passage is short to the Stone Gallery, on the outside of the dome; and by a more difficult ascent, the Golden Gallery is gained. From this point, in clear weather, the view of the surrounding city and its environs is most comprehensive and striking. Above this gallery are the ball and cross, the former 6 feet in diameter, and capable of containing eight persons. St Paul's is the cathedral church of the see of London,—the most important

London. bishopric in the empire, the incumbent ranking next after archbishops, and enjoying an income of L.10,000 a-year. The revenues of the diocese, which includes the whole of Middlesex and parts of Surrey, Essex, and Kent, are estimated at upwards of L.30,000 a-year. The affairs of the cathedral are managed by a dean and chapter, consisting of four canons residentiary, four prebendaries, and other officers.

Westminster abbey. Westminster Abbey, the scene of so many important events, and so full of historic associations, claims even more minute attention than the sister cathedral. The accounts of its origin are nearly as vague and uncertain as those of old St Paul's. According to tradition, it originally stood on an island in the river, formed, it is supposed, by a branch of the Thames which inclosed parts of Pimlico and Westminster. At any rate, there is good reason for believing that the Abbey existed before the end of the eighth century. It was rebuilt by King Edgar, and extended and enriched by Edward the Confessor. The larger portion of Westminster Abbey, as it now stands, was built by Henry III., and completed in 1245. Like most cathedrals, it is in the form of a cross, though somewhat irregular, from the addition of chapels and cloisters at various times. The length of the Abbey, exclusive of Henry VII.'s chapel, is 383 feet; the extreme breadth at the transept, 203 feet; the height of the nave being 102, and that of the towers 225 feet. Henry VII.'s chapel, at the eastern extremity, is a gorgeous specimen of the Gothic architecture of his time. It was commenced in 1502, built by him as a burial-place for the royal family, and cost L.14,000. The Abbey subsequently suffered from neglect, especially after the suppression of religious houses, and during the civil wars of the seventeenth century. Soon after the Revolution, the whole was thoroughly repaired, and the western towers were added by Wren. Sir Christopher, however, could not shake off his innate love for classic ornament, with which, to the horror of the critics, he has liberally invested the Gothic towers.

The Abbey is much hidden by St Margaret's Church; but on approaching Victoria Street from Parliament Street, the buttresses and pinnacles, and whole expanse of this majestic pile, gradually open to view. The entrance to the north transept is much and deservedly admired, and convinces us that the wisdom of our ancestors in matters of architecture is not surpassed at the present day.

The interior is well seen on entering from this side, and still better from the western door. The stone screen separating the choir from the nave is modern, and designed by Mr Blorc. Beyond the high altar and further east, are nine chapels, the chief being those of Edward the Confessor and Henry VII. The first contains the shrine of that monarch, with, *inter alia*, the tombs of Henry III., and his son Edward I. Here, too, are preserved the sword of Edward I., part of his shield, and the Scotch coronation stone, brought by him from Scone in 1296. The chapel of Henry VII., beyond that of Edward the Confessor, forms the eastern extremity of the cross. It suffered by fire in 1803, but underwent a thorough repair between 1810 and 1822 at a cost of L.42,000. Chapters of the Order of the Bath were formerly held in this chapel; and on entering, the stalls and banners of the knights attract immediate attention. The next object in prominence is the highly decorated altar-tomb of the founder, bearing effigies of himself and wife. The flat stone ceiling, elaborately ornamented, is worthy particular notice. In and around this chapel are other monuments of interest, such as those to Mary of England; Mary Queen of Scots; Queen Elizabeth; George Villiers, Duke of Buckingham, assassinated by Felton; Monk, Duke of Albemarle; and of modern date, one to the Duc de Montpensier, brother to the late Louis Philippe, ex-King of the French. Many royal personages lying in the vaults beneath, such as Charles II., William

and Mary, &c., have had no monuments erected to them. In the other private chapels are many antique monuments and brasses.

In the south transept, in and near Poets' Corner, are monuments to the majority of our most illustrious poets, from the time of Chaucer to that of Campbell; and here, as well as in both aisles of the nave and choir, and in the north transept, the profusion of monuments almost bewilders the eye. The names of naval and military heroes, statesmen, historians, philosophers, divines, lawyers, painters, sculptors, musicians, actors, &c., attract one at every turn. The cloisters on the south side of the Abbey are in good preservation, and filled with monuments.

Service is performed daily, and on Sundays the Abbey is much frequented for public worship, though the sermons can rarely be heard by above one-third of those present.

The governing body of this collegiate church consists of a dean and chapter of eight prebendaries, &c. The property belonging to the Abbey being chiefly in the metropolis, is very valuable, and considerable sums are spent, and usually with good taste, in renovating and decorating this national temple.

Of the minor churches, the most remarkable, bearing date prior to the fire of London, are,—St Saviour's, Southwark, the Temple Church, the Savoy and Whitehall Chapels, and St Margaret's, Westminster.

St Saviour's, Southwark, formerly a priory, and one of London's oldest churches, is a most interesting fabric. It has three aisles running E. and W., and a cross aisle; and the columns supporting the roof are remarkably graceful. The Lady Chapel, restored in 1832, and at the east end of the church, is much admired. Gower the poet, Fletcher the dramatist, and Massinger, are all buried here—the first having a good monument in the porch.

The Temple Church, situate in the Inner Temple, is quite a gem of its kind, having been restored in 1842, at a cost of L.70,000, defrayed by the two societies of the Inner and Middle Temple. The entrance, by a very fine Norman arch, leads into the circular portion of the church, which dates from 1185, and is modelled from the Holy Sepulchre at Jerusalem. This part is peculiarly interesting from its form, its age, and the effigies of cross-legged and recumbent knights, that lie grouped on the floor. The inner portion of the church, built about 1240, is early English in style, rectangular in form, and the dark marble pillars which support the roof, are especially beautiful. Selden and Goldsmith were buried here.

Savoy Church, or St Mary-le-Savoy, near the Strand, is perpendicular in style, with a highly decorated and painted roof, and has many quaint monuments. It was built in the beginning of the sixteenth century, and was originally the chapel of an hospital for 100 poor men, founded on the site of old Savoy Palace by Henry VII., and dedicated to St John the Baptist.

Whitehall Chapel, opposite the Horse Guards, was the celebrated banqueting house, and is now the only remaining fragment of Whitehall Palace. This great work of Inigo Jones is 110 feet long, of hewn stone, adorned by an upper and lower range of pillars and pilasters of the Doric and composite orders. The interior is almost engrossed by one apartment of an oblong form, upwards of 40 feet high, with a ceiling painted by Rubens. It is now used as one of the chapels royal. Through one of the windows of this building Charles I. was led to the scaffold on 30th January 1649.

St Margaret's, Westminster, chiefly observable as impeding the view of Westminster Abbey, is also remarkable as the resort for public worship of the House of Commons on solemn occasions. It is of the time of Edward I., but has been repaired and renovated at various periods, and contains tablets to the memory of Caxton the printer and Sir Walter Raleigh.

London.

The churches worthy of notice, of a date later than 1666, are chiefly works of Sir Christopher Wren and his disciples, and belong to the Established Church. St Stephen's, Walbrook, considered by critics as the best of Wren's small churches; Bow Church, Cheapside; St Bride's, Fleet Street; St Stephen's, Holborn Hill; St Clement Danes, and St James's, Piccadilly, are all by the same hand. St Martin's-in-the-Fields and St Mary-le-Strand, by Gibbs, and St George's, Hanover Square, by James; and, of a later date, St Pancras New Church, by Mr Inwood; Marylebone New Church, by Hardwicke; St Luke's, Chelsea; and Miss Coutts' Chapel, in Westminster, are all worthy of attention. Of the 640 churches and chapels belonging to Dissenters, though they form the vast majority in the metropolis, few deserve remark on account of architectural beauty. The most striking exceptions, perhaps, are the cathedral-like building in Gordon Square, belonging to a sect calling itself the Apostolic Church, and the Roman Catholic cathedral, in St George's Fields, built by the late Mr Pugin, in the decorated style, though one side of the latter is nearly hidden by houses in the neighbourhood.

Inns of court.

Perhaps, of all the existing institutions in London connected with the law, the inns of court are the most interesting, partly from their antiquity and peculiar constitution and objects, and partly from their wealth and influence. The four great inns, or societies having the power to call students to the bar, are,—the Inner Temple, Middle Temple, Lincoln's Inn, and Gray's Inn. When these "voluntary societies," or aggregations of lawyers, originated, has not been exactly ascertained; but though not incorporated, they have "for ages submitted to government analogous to that of other seminaries of learning." (Lord Mansfield, quoted in Spilsbury's *Lincoln's Inn*.) These societies consist of three grades,—viz., benchers, barristers, and students. The oldest of these inns is the Temple, deriving its name from the religious and military order of the Knights-Templars, who founded it in 1185, and possessed it till the extinction of the order in 1311. In the reign of Edward III. the students of common law leased this property, and at length acquired it by gift from James I., who ordered that none should be admitted "into the society of any inn, that is not a gentleman by descent." The societies of the Inner and Middle Temple form two distinct bodies, having separate revenues and regulations; the Temple church, already described, being alone held in common. The whole of the very large property attached to the Temple, extending from Fleet Street to the Thames, except the gardens on the bank of the river, is covered with buildings, and these are divided into suites of apartments for lawyers, or others who choose to resort hither.

Lincoln's Inn lies chiefly between Chancery Lane and Lincoln's Inn Fields, and acquired its name from the inn or residence built here by Henry de Lacy, Earl of Lincoln, who died in 1312. This and part of the property of the bishops of Chichester, acquired in the time of Henry VII., constitute the present Lincoln's Inn. The Gothic chapel was built by Inigo Jones; but he, like Wren, seems to have succeeded best in classic architecture. The hall of the society a magnificent structure, 120 feet long, in the Tudor style, was completed by Hardwicke in 1845. The library attached to the hall contains a large and very valuable collection of books and MSS. Among the eminent men who once studied at Lincoln's Inn may be mentioned Sir Thomas More, Oliver Cromwell, Sir Matthew Hale, Lord Mansfield, Pitt, Perceval, and Canning.

Gray's Inn, the last of the four chief inns, is entered from Holborn, and stretches along Gray's Inn Lane. It was the property of the Lords Gray of Wilton in 1505, when it was sold, and afterwards vested in the prior of Sheen, who granted a lease of it to the students of law, renewed by Henry VIII. after the Reformation. The

hall and chapel are not remarkable, but the gardens are spacious and well kept. Lords Burleigh and Bacon were of "Graie's Inn." In 1850 the members of the four inns of court numbered upwards of 4000. Attached to the four great inns are nine smaller ones,—viz., Clifford's, Clement's, Lyon's, New, Strand, Furnival's, Thavies', Staple's, and Barnard's Inns.

London.

The chief courts of law are held partly in Lincoln's Inn, Courts of law, &c. and partly in a building attached to the west side of Westminster Hall, already alluded to as the grand vestibule to the Houses of Parliament. In the latter, several doors on the right lead to the Courts of Queen's Bench, Common Pleas, and Exchequer, of the Chancellor, Master of the Rolls, Lords Justices of Appeal, and Vice-Chancellors. But it is proposed, in completing the Houses of Parliament, to sweep away this building as inconvenient, and as an unsuitable architectural adjunct to Westminster Hall. The new site for the courts has not yet been definitively settled. In vacation, the Chancellor sits in the Old Hall, Lincoln's Inn, and the Master of the Rolls in Rolls' Court, Chancery Lane. The civil law courts,—viz., the Ecclesiastical and Admiralty,—are held in Doctors' Commons. The chief ecclesiastical courts are,—the Prerogative Court and the Court of Arches; and under the superintendence of the former is the registry of wills for the province of Canterbury. At present (1857) there are bills before Parliament to alter and limit the jurisdiction of these courts. The Court of Admiralty decides all cases as to capture of ships, disputes between masters and sailors in merchant ships, &c.

The inferior courts are those of Bankruptcy in Basinghall Street, the Insolvent Debtors' Court in Portugal Street, the Duchy Court of Lancaster in Lancaster Place, the courts of the lord mayor, and of the sheriffs, &c. There are also attached to the metropolis ten of the new county courts for the decision of claims under £50; and the committee of county court judges, established in 1856, act as a court of appeal.

The principal, or Central Criminal Court, is that held at the Old Bailey, its jurisdiction being a circle of ten miles round St Paul's. Nominally the lord mayor presides in this court, but the prisoners are for the most part tried by the judges of the Courts of Queen's Bench, Exchequer, and Common Pleas, and a few by the recorder or common serjeant of the city. Inferior offences are tried before the assistant-judge at the Middlesex Sessions House. The lord mayor sits at the Mansion House, and one of the aldermen at Guildhall, to judge in smaller matters, and there are besides eleven other metropolitan police courts beyond the limits of the city. The magistrates of these thirteen courts have the power to punish by fine and imprisonment for disorderly conduct, and for minor offences, to inquire regarding crimes of the highest nature, and to send prisoners for trial to the Central Criminal Court.

The College of Physicians in Pall Mall and Trafalgar Colleges of Square was founded in 1518, and the present is the third physicians building occupied by them since their institution. It was and surgeons built by Smike, opened in 1825, and contains some interesting portraits of eminent physicians, such as Harvey, Sir Thomas Browne, Garth, and Sir Hans Sloane, with busts of Drs Mead, Sydenham, Baillie, &c. The college consists of fellows and licentiates; and to the examinations conducted here we have already adverted.

The College of Surgeons in Lincoln's Inn Fields was erected by Sir Charles Barry in 1835, and contains the celebrated Hunterian Museum, purchased by the government, and entrusted to the college. Admission is obtained by an order from a fellow. This college originated in the Company of Barber Surgeons, chartered in 1461.

Chelsea Hospital, for maimed and superannuated soldiers, Chelsea is supported by government, and is similar in its origin hospital and objects to the twin establishment at Greenwich for

London. sailors. Chelsea College, partially built in the time of James I., by Dr Sutcliffe, dean of Exeter, was intended for a polemical school of divinity, but this having proved a failure, the property fell to the crown. It was granted by Charles II. in 1667 to the Royal Society, but reconveyed to the crown in 1682 for L.1300. An hospital, or infirmary, for old or wounded soldiers was commenced by Wren in that year, and completed in 1690 at a cost of L.150,000. It is of brick, with stone quoins, having a front of 790 feet, and walks and gardens upwards of 40 acres in extent. The main building forms three sides of a quadrangle, in the centre of which stands a bronze statue of Charles II. The principal portion of the front is devoted to the chapel, hall, &c., and the two remaining sides are occupied by pensioners (538 in 1856), who are well clothed, lodged, and fed. The out-pensioners, a far larger body, numbering 59,987 in 1856, are scattered all over the kingdom. Near the hospital is the Royal Military Asylum, opened in 1803 for the maintenance and education of the orphan children of soldiers. It consists of a normal school for training regimental schoolmasters, and of model and infant schools; and the boys, of whom there are at present 479, are trained to military exercises and trades, and are dressed in uniform.

Benevolent
institutions.

Among the most important of the benevolent institutions are those for the cure or alleviation of disease or external injury, such as hospitals, infirmaries, dispensaries, &c. Of these there are no less than 177 enumerated in the *London Post-Office Directory* for 1857.

St Bartholomew's Hospital in West Smithfield was originally founded in 1102 by Rahere, prior of St Bartholomew, and refounded in 1547 by Henry VIII. It was rebuilt in 1720 by voluntary subscription, and is well supported. The establishment makes up nearly 600 beds, and the average number of outdoor and indoor patients annually relieved is upwards of 70,000.

St Thomas's Hospital in High Street, Southwark, was founded by the prior of Bermondsey in 1213, and refounded by Edward VI. Rebuilt by voluntary subscription in 1693, and extended in 1752, it was again partially rebuilt in 1836. It consists of eighteen wards, possesses about 480 beds, has a revenue of L.25,000 per annum, and, on the average, annually affords assistance to upwards of 45,000 in and out patients.

Guy's Hospital, a near neighbour of St Thomas's Hospital, owes its existence to Thomas Guy, a bookseller, who built it and left at his death, in 1724, L.219,499 for its support. Again in 1829, Mr Thomas Hunt bequeathed to this institution L.200,000. Its ample resources are turned to good account. Here are 544 beds, which are filled every Wednesday morning by applicants whose cases appear the most urgent. There is a separate lying-in charity supported by this hospital, where 1755 cases of confinement were attended in 1856.

To this class belong also,—Westminster Hospital, Broad Sanctuary; St George's Hospital, Hyde Park Corner; London Hospital, Whitechapel Road; Charing Cross Hospital, West Strand; Middlesex Hospital, Charles Street, Regent Street; Royal Free Hospital, Greville Street, Hatton Garden; Metropolitan Free Hospital, Devonshire Square, City; King's College Hospital, Portugal Street, Lincoln's Inn; University College Hospital, Gower Street; St Mary's Hospital, Cambridge Place, Edgeware Road; and the Scamen's Hospital, on board the "Dreadnought," off Greenwich. To the great majority of these institutions are attached medical schools, where lectures, delivered by those eminent in the profession, and illustrated by practice, are available for an almost unlimited number of students.

There are, again, establishments devoted to the cure or relief of particular diseases, such as the hospitals for consumption in Brompton, the City Road, and Victoria Park; for small-pox, in Upper Holloway, &c.; for diseases

of the eye, in Finsbury, Chandos Street, Charing Cross, and Burlington Gardens; besides hospitals for the treatment of cancer, the Lock Hospital, &c.

The lying-in hospitals, too, are very numerous; and there are eleven asylums, &c., for the relief of the blind, and deaf and dumb. The Foundling Hospital, founded by Captain Coram, and incorporated 1739, though not now a charity for foundlings, maintains and educates 500 poor children. Of the lunatic asylums, besides those in the suburbs, the chief is,—

Bethlehem or Bedlam Hospital, which originated in the priory of St Mary of Bethlehem, founded for lunatics in 1247. Removed from its original site to Bethlehem, without Bishopsgate, it was given by Henry VIII. to the city in 1545; and, after being again moved to a new site in Moorfields about 1675, it finally was planted in its present position in St George's Fields in 1814. The front of the hospital is magnificent, extending to 697 feet,—the centre being surmounted by a dome and supported by six Ionic columns. The interior is well arranged, warmed, and ventilated; and having been gradually extended down to the present day, it is now capable of receiving about 500 patients.

St Luke's Hospital, a similar institution, more especially devoted to incurables, is situate in Old Street, having been brought hither in 1752 from Windmill Hill, where it was first instituted in 1732.

The numerous institutions for rearing and educating poor children are alluded to elsewhere. Of the infinite number of miscellaneous charities may be mentioned,—the Royal Literary Fund for the relief of poor authors and their families. The fund consists of L.30,000 funded property, and L.200 a-year derived from land, besides subscriptions. The Royal Humane Society, for rewarding those who assist in the preservation of drowning persons, and for resuscitating the latter; the Society of Friends of Foreigners in Distress; the Society for the Relief of Persons Imprisoned for Small Debts, by which 263 poor prisoners were discharged in 1855; the Magdalen and Guardian Asylums for prostitutes; the Society for the Suppression of Vice; and the Society for the Prevention of Cruelty to Animals.

Since the introduction of printing, London has always been the chief resort of the literary men of this country, as well as the head-quarters of the bookselling trade. Now, more than ever, it is the centre of English literary circles, the periodicals, exclusive of newspapers, being almost entirely confined to the capital. Its newspapers, too, excel in ability, information, and circulation, any others in the world. We subjoin a statement showing the number of periodical publications produced in London in January 1857:—

	Number.	Price per Copy.
Daily newspapers.....	16	1d. to 4d.
Newspapers issued thrice per week.....	6	1d. to 5d.
Ditto issued twice a-week.....	4	3d. to 1s. 4d.
Ditto once a-week.....	86	1d. to 1s.
Ditto at more distant intervals.....	24	3d. to 1s. 6d.
<hr/>		
Total newspapers and stamped publications.....	136	
Weekly magazines, and weekly issues of serial works.....	46	0½d. to 1s.
Monthly magazines, &c. do.	335	0½d. to 10s.
Quarterly reviews, &c. do.	57	1d. to 7s. 6d.
Transactions of various societies.....	26	2s. 6d. to 40s.
<hr/>		
Total.....	464	

Besides these there are numerous works published once or twice per annum, and of these the most worthy of remark is *Kelly's London Post-Office Directory*, an enormous octavo, issued regularly in November and March.

Many books have been published regarding London, but few of them are remarkable. Stow's *Survey of London*,

London.

first published in 1598, and since improved by Strype, &c., (in 2 vols. folio, 1754), is the most famous. The works of Maitland and of Pennant are also good. In the *Handbook to London*, of 1850, Mr Peter Cunningham has amassed a very large amount of information of the most entertaining kind regarding the antiquities of London; and Mr Henry Mayhew, in his work on *London Labour and London Poor*, has collected a wonderful amount of curious matter and statistics on his branch of the subject. But a good and comprehensive work on London, applicable to past and present times, is much wanted, and would, if well executed, form a valuable addition to English literature.

British
museum.

The British Museum, in Great Russell Street, Bloomsbury, has been established for upwards of a century; old Montague House, in which it was first deposited, having been purchased by government from Lord Halifax in 1753. The present building, erected 1823-47, from designs of Sir R. Smirke, stands on the site of the former one. The nucleus of this noble national museum was formed by the collections of Sir Robert Cotton and Sir Hans Sloane; the former acquired in 1700, and the latter purchased by government for £20,000 in 1753. The Museum has since been enriched by the following, among other acquisitions:—the Harleian MSS., purchased in 1755; the Royal Library, presented in 1757, by George II.; the Lansdowne, Hargrave, and Burney MSS., purchased between 1806 and 1818; the noble Library of George III., presented by George IV. soon after his accession, and that of the Right Hon. Thomas Grenville, devised by will, and transferred to the Museum in 1846.

The collection of antiquities is magnificent, consisting of,—1. The Egyptian antiquities, including the trophies of the Egyptian expedition of 1801, presents from various noblemen and gentlemen, and purchases, especially from the collections of Lord Belmore, Mr Henry Salt, and Signor Anastasi. 2. The Elgin marbles, containing the best specimens of Grecian art, purchased for £35,000. 3. The Phigaleian frieze. 4. The Towneley, Greek, and Roman marbles. 5. Sir William Hamilton's Greek and Etruscan vases. 6. Richard Payne Knight's fine collection of coins and medals, with the bequest of Rev. C. M. Cracherode, and the donations of Lady Banks and Mr W. Marsden.

The last great additions, and perhaps the most interesting, are the Nimroud marbles, collected from the ruins of Nineveh and Babylon by Mr A. H. Layard.

The collections of natural history are also extensive, especially in mammals, birds, and insects; while the mineral department contains the choice cabinet of Fulke Greville, with numerous additions, and a very fine assemblage of organic remains.

The governing body consists of *official* trustees, or personages high in the government, church, law, &c.; *family* trustees,—two of the Cotton family, two of the Harley, two of the Sloane, and one each of the Towneley, Elgin, and Knight families; and fourteen elected trustees, all eminent men.

From 7th May to 1st September, the Museum is open to the public from ten till six o'clock on Mondays, Wednesdays, and Fridays; closing at four o'clock from 1st November to 28th February; and at five o'clock during the rest of the year. Access to the reading-room (now, 1857, on an enlarged scale) attached to the library may be obtained by written application to the librarian, who issues tickets of admission available for six months. (See LIBRARIES.)

The number of visitors to the Museum in 1855, was 334,089 (in 1850, 2,527,216); the number of visitors to the reading-room being, in 1855, 53,567.

The annual expenditure of the Museum trustees is about £60,000, which is chiefly defrayed by the public.

The Geological Museum in Jermyn Street, a branch of the Government Department of Science and Art, is also open to the public. It contains specimens of British mien-

erals, raw and manufactured; and lectures are delivered here on mining, metallurgy, &c. London.

Though not open for general inspection, access may easily be obtained to Sir John Soane's Museum in Lincoln's Inn Fields, and that of the United Service Institution in Whitehall Yard, and they both merit a careful examination.

Exclusive of the government institutions for the promotion of science and art, there are many voluntary associations having the same object. Of these, the first in rank and antiquity is—

The Royal Society, Somerset House, incorporated in 1663, and well known from its *Philosophical Transactions*, published since 1665. The Society of Antiquaries, founded 1707, has also apartments in Somerset House. Its researches have been given to the public in *Archæologia*, first published in 1770. The Society of Arts, John Street Adelphi, established in 1754 for the encouragement of arts, manufactures, and commerce, was incorporated in 1846; and with a kindred object arose the Great Exhibition of 1851 and its Crystal Palace.

There are also, among many more, the following, bearing names indicating their character and objects:—The Medical Society, established 1773. Linnæan Society, founded 1785, and incorporated 1802. Horticultural Society, established 1804, and incorporated 1808. Medical and Chirurgical Society, established 1805. Geological Society, established 1807, incorporated 1826. Astronomical Society, established 1820, incorporated 1831. Asiatic Society, for research into eastern literature, founded in 1823. Society of Literature, founded in 1821, and incorporated 1825. Zoological Society, founded in 1825, and incorporated 1829; has an extensive collection of animals in Regent's Park. Geographical Society, incorporated 1830. Statistical Society, founded in 1834. Royal Botanical Society, incorporated 1839, and possessing 18 acres of garden in Regent's Park. Institute of British Architects, established 1834, and incorporated 1837. Institution of Civil Engineers, established 1818, incorporated 1828. Ethnological Society, Newman Street, Oxford Street; Numismatic Society, Gate Street, Lincoln's Inn; the Archæological Institute and Archæological Association, both branches of the Society of Antiquaries, and established in 1843. Most of these societies publish journals or transactions at stated periods; and they generally hold meetings weekly or every alternate week during six months of the year, from November to June.

There are also numerous institutions which partake, to some extent, the character of clubs, where newspapers and periodical publications are furnished to subscribers, and lectures are delivered by eminent men on various subjects. The oldest and most important of these is—

The Royal Institution in Albemarle Street, founded in 1799. Here Sir Humphry Davy and Sidney Smith delivered lectures, and Dr Faraday still maintains its reputation. It has a tolerable library and the current periodical literature of the day for the use of members. The London Institution in Finsbury Circus, the Russell Institution in Great Coram Street, the Marylebone, the Westminster, and the Pimlico Institutions, and a host of others, are all of the same class.

Again, the mechanics' institutes are after the same model, though on a smaller scale, and of these there are several in the metropolis. The circulating libraries are also very numerous; but perhaps the most important is the London Library in St James's Square, which now contains 78,000 volumes, collected within the last sixteen years. The Library of Sion College, London Wall, founded 1623, and that in Red Cross Street, established by Dr William's, who died 1716, are open to all respectable persons, and contain together about 60,000 volumes.

The National Gallery, which contains the chief portion of the national collection of paintings, constitutes the north side galleries.

London. of Trafalgar Square, and occupies one of the best sites in the metropolis. The foundation of the collection was made in 1824 by the purchase of Mr Angerstein's collection, but it has chiefly been increased by donations. The Gallery was erected in 1834-38, has a frontage of 460 feet, and contains, in all, ten rooms for pictures; this accommodation being shared equally by the trustees of the Gallery and by the Royal Academy. It contains many specimens of the Italian and Flemish, and a few of the Spanish schools; of which last the Holy Family, by Murillo, is a remarkably fine picture. There are, too, some good Claudes and Poussins in the gallery. In consequence of the late gifts to the public of the collections formed by Mr Vernon and Mr Sheepshanks, and of his own works bequeathed by Mr J. W. M. Turner, the moiety of the Gallery is now quite insufficient for the whole. On this account a portion, chiefly of the English school, has been temporarily removed to Marlborough House; and a royal commission is now (1857) sitting to fix upon a site for a new Gallery. The rooms in Trafalgar Square and Marlborough House are open to the public from Monday to Thursday inclusive, and to students on Tuesdays and Saturdays. A royal commission has this year (1857) been appointed for the formation of a portrait gallery in honour of distinguished men.

The chief private collections are those of Her Majesty, the Duke of Sutherland, the Marquis of Westminster, Marquis of Hertford, Earl of Ellesmere, Lord Ward, Sir Robert Peel, Mr Hope, Mr Thomas Baring, Mr Holford, &c.

Art Institutions.

The Royal Academy, chartered in 1768, is established under the same roof as the National Gallery. Here lectures on the fine arts, which now form part of the literature of the country, have been delivered by Sir Joshua Reynolds and other eminent presidents of the Academy. A good collection of paintings and casts, and copies from famous statues, are kept in the Academy for the use of students; and works of living artists in painting and sculpture are annually exhibited here. The sale of tickets yields the Academy a revenue of L.5000 or L.6000 a-year.

The British Institution, founded in 1805, is composed of amateurs, who, for the culture of public taste, lend and borrow good pictures, and exhibit them annually in their gallery, in Pall Mall.

The Society of Painters in Water Colours, established in 1804, has an annual exhibition of productions in this branch of art at 5 Pall Mall East.

The Society of British Artists in Suffolk Street, Pall Mall, is comprised of a section of artists who disapprove of the Royal Academy, or whose works have been rejected there.

The Art Union of London consists of a varying body of subscribers, to some of whom valuable works of art are distributed by lottery, and who all receive annually an engraving from the work of some British artist.

Of the societies for the cultivation of music,—

The Royal Academy of Music in Tenterden Street, Hanover Square, was founded in 1822. It affords tuition, vocal and instrumental, to indoor and outdoor students, on the payment of certain fees. There are, besides, the Sacred Harmonic at Exeter Hall, the Philharmonic, and several other similar societies.

Clubs.

London is especially remarkable for its clubs. The chief of these are the following:—

IN PALL MALL:—
Army and Navy.
Athenæum.
Carlton.
Guards'.
Oxford & Cambridge.
Reform.
Travellers'.

United Service.
United University.
IN ST JAMES'S STREET:—
Arthur's.
Boodle's.
Brooks's.
Conservative.
White's.

With the Junior United Service, in Charles Street, St James's; the Union, in Trafalgar Square; Oriental, in Hanover Square; and the City Club, in Old Broad Street.

Of all the clubs, White's is the oldest and most exclusive, dating its foundation about 1698, and reminding us of the White's chocolate-house of the *Tatler*, and of the days of Addison and Steele. It has not, however, the architectural pretensions of the club-houses in Pall Mall, some of which are copies after celebrated Italian palaces. Thus the Army and Navy Club is a pretty close imitation of the Palazzo Cornaro on the Grand Canal at Venice. These establishments are furnished in a very sumptuous manner, and afford a very luxurious style of *cuisine*. The number of members is usually limited, but varies in the different clubs from 300 to 2000. The members are elected by ballot; their entrance-fee varying from 9 to 30 guineas, and annual subscription from 5 to 12. All the clubs are provided with the newspapers and publications of the day, and some of them have extensive and valuable libraries. A few of these establishments, such as Brooks's, the Carlton, Conservative, and Reform, are of a political nature; others are exclusively professional, such as the two United Service, and the Army and Navy Clubs; and some are of a miscellaneous character.

London.

The largest monuments in London are "The Monument," the York and Nelson Columns, and the Wellington Arch. The first, a fluted Doric column 202 feet high, on Fish Street Hill, was constructed in 1671-8, from a design by Wren, to commemorate the great fire of 1666. The offensive inscription on its base, attributing the fire to the Roman Catholics, was removed in 1830.

Monuments and statues.

The column to the late Duke of York, raised in 1833, is at the top of the steps leading from Waterloo Place into St James's Park. It is plain Doric, 124 feet high, built of granite, and surmounted by a statue, 14 feet high, of his royal highness.

The Nelson column is fluted Corinthian, 176 feet high, having on the top a statue of the naval hero by Baily, and on the base sculptured reliefs illustrative of his death and the great events of his life.

The Wellington Arch, at the top of Constitution Hill, was erected from designs by Decimus Burton in 1828, and appropriated in 1846 to the support of an equestrian statue, by Matthew Wyatt, of the late Duke of Wellington.

The equestrian statues are those of Charles I., by I. e Soeur, at Charing Cross; William III., by Bacon, in St James's Square; of William, Duke of Cumberland, in Cavendish Square; of George III., by Wyatt, in Pall Mall East; George IV., in Trafalgar Square; and the Duke of Wellington, by Chantrey, in front of the Royal Exchange. The others of note are of Elizabeth, James I., Charles I., and Charles II., on Temple Bar; of James II., by Gibbons, in Whitehall Gardens; of Queen Anne, by Bird, in front of St Paul's; of William IV., in King William Street, City; of Her present Majesty, in the court of the Royal Exchange; of Pitt and Fox, in Hanover and Bloomsbury Squares; of the Duke of Wellington, in the Tower; of Sir Robert Peel, in Cheapside; of General Sir Charles Napier, in Trafalgar Square, &c.

London, in proportion to its extent and wealth, has fewer theatres than any other European capital. The largest and most fashionable is Her Majesty's Theatre, or the Italian Opera House, in the Haymarket. Burned down in 1789, it was rebuilt in 1790, and enlarged by Nash in 1818. It is now capable of containing 2500 persons; the boxes and stalls being private property, or let for the season, and the pit and gallery open, on payment, to the general public. The entertainments consist of operas and ballets; the singers, dancers, and musicians being almost exclusively foreigners; but though this house is liberally patronized, especially by the higher classes, far beyond the national theatres, it usually proves ruinous to any one bold enough to undertake its management.

Theatres

Drury Lane Theatre, in Brydges Street, the only patent

London.

establishment since the destruction by fire of Covent Garden Theatre in 1856, nominally enjoys a kind of monopoly of the legitimate drama. The present building is the fourth of a series erected here since 1663, two of which were burned in 1672 and 1809. That now in existence, built in 1811, and improved in 1820, has, it is said, sitting room for an audience of 3500. The regular drama having fallen into neglect of late, partly from the dearth of histrionic talent, and partly from the strong tendency of fashion towards musical entertainments, this house is now very often devoted to operas and dancing.

The Haymarket Theatre, first started in 1720, and rebuilt in 1821, and the Princess's Theatre in Oxford

Street, are both small, but well managed and successful.

London.

Besides these there are about seventeen minor theatres, not demanding particular notice here.

During the summer season the gardens at Vauxhall and at Cremorne, and the Surrey Gardens, are usually open in the evenings. Displays of fire-works, horsemanship, balloon ascents, music and dancing, form the chief attractions to those places.

The bridges spanning the Thames in its passage through Bridges.

London are 9 in number, 8 of these being adapted for carriages. The following table will show the cost and dimensions of these various bridges:—

Table showing the Material, Cost, &c., of the Bridges over the Thames, in London and its vicinity (compiled from McCulloch's Geographical Dictionary, and Parliamentary Paper (193) of Sept. 1856.

NAMES.	Date of completion.	Material.	Cost, including Approaches.	Cost, exclusive of Approaches.	Number of Arches.	Length.	Breadth.	Span of Central Arch.
			L.	L.		Feet.	Feet.	Feet.
London Bridge.....	1831	Granite	2,000,000	542,150	5	904	53	150
Southwark	1819	Iron arches, stone piers	800,000	384,000	3	800	42	240

Chelsea Suspension	1857	Iron piers & roadway	88,000	922	45	...
Battersea	1770	Wood	Not known.

N.B.—The cost of New Westminster Bridge is estimated at L.235,000.

None of the existing bridges have any interesting associations connected with them, except London Bridge, and that only in right of its predecessor, so well known as Old London Bridge. In 1209 the latter (the first stone bridge) was built, and by dint of occasional repairs, it existed for upwards of six centuries. But the obstruction to the tides offered by its peculiar formation, proved so serious an evil, that it was at length necessarily doomed, and one of London's quaintest features disappeared in 1834. New London Bridge, begun in 1824, and completed in 1831, is placed about 200 feet farther up than the old one. It is built of granite, and was designed by the late John Rennie.

Proceeding up the river, the second is Southwark Bridge, leading from Queen Street, City, to Southwark. It was begun by Mr Rennie in 1814, completed in 1819, and is composed chiefly of cast-iron. It was constructed at the expense of a joint-stock company, by whom the tolls are levied.

Blackfriars Bridge, the next in position, commenced in 1760, was finished in 1770. It stands midway between Waterloo and Southwark bridges, and has unfortunately, within the last few years, shown symptoms of decrepitude.

Waterloo Bridge, the most admired of all, comes next, and was commenced in 1811, and finished in 1817. The arches, nine in number, are elliptical, and each 120 feet wide, so that its symmetry is perfect and its roadway a dead level. It was built by the late Mr Rennie for a joint-stock company, and is undoubtedly his greatest work. Canova declared it to be the finest feature of London. But though most ornamental to the city, it is, in consequence of its toll, but little frequented.

Hungerford Suspension-Bridge, opened in 1845, is the only one exclusively for foot passengers; but the proprietors, who levy tolls, contemplate widening the bridge for a carriage-way. It springs on the Middlesex side from Hungerford market, and rests on the Surrey side, near the terminus of the South-Western Railway.

Westminster, the oldest of the metropolitan bridges, was begun in 1739, and completed in 1751. The roadway has been materially lowered within the last twelve years;

and the lofty stone balustrade which obstructed the view has been removed, and an unsightly wooden boarding substituted. From the very low situation of the New Houses of Parliament, they are to some extent hidden by this bridge, and it is therefore proposed to build another more in harmony with them.

Vauxhall Bridge, next in order, was commenced in 1813, and finished in 1816, by a joint-stock company still in receipt of the tolls. It affords ready communication with Surrey to Belgravia and other new districts lately created by Mr Cubitt and the Marquis of Westminster.

Chelsea Suspension-Bridge, commenced in 1851, is all but finished, and will be opened this year (1857). It connects Chelsea with the new park at Battersea, and, taken in conjunction with it and the embankment of the Thames from Vauxhall Bridge to Cheyne Walk, forms a gigantic undertaking.

Battersea Bridge, a wooden structure, connects Chelsea with Battersea, and is the last of the bridges within the metropolitan boundaries. It belongs to a body of about thirteen proprietors, who levy tolls, and derive about L.500 per annum each as net revenue.

The tunnel under the Thames, one of the wonders of Thames London, is situate about 2 miles below London Bridge, tunnel. starting from the Middlesex side of the river in High Street, Wapping, and leading into Rotherhithe, on the Surrey side. This great achievement was effected by the late Sir Isambert Brunel, the distinguished inventor of block machinery, &c. It was undertaken for a joint-stock company, incorporated in 1824; and the expense was originally estimated at L.160,000. The tunnel was commenced in 1825, and, after repeated accidents from invasions of the river, it was, with the assistance of government grants, completed in 1840. It is of brick, and its form is cylindrical; a tube nearly 1200 feet long being cut by a longitudinal division into two equal parts or roadways, 15 feet high by 12 broad. It is entered at either end by long descending stairs; and this difficulty of approach, and other circumstances, have hitherto rendered this great triumph of science and perseverance of comparatively little service to

London. the public. It is used to some small extent by passengers, but chiefly visited as a curiosity.

Corpora-
tion of
London. Though the government of by far the greater part of the metropolis is intrusted to the secretary of state for the home department, and administered under him by the commissioners of police; yet that portion known as *The City*, is under the exclusive superintendence of the Corporation of London, a body wielding considerable power, and possessed of extensive property.

The origin of this body has been shortly alluded to in the commencement of this article. It consists of the lord mayor, the court of aldermen, 25 in number, exclusive of his lordship, and 206 members forming the court of common council. The lord mayor is chosen annually from among the aldermen, but is capable of re-election. The right of nominating two aldermen worthy of election to the dignity, is restricted to those freemen of the city who have been admitted into the livery of their respective guilds or companies. The court of aldermen then decide which of the two is to be promoted. The number of livery-men in 1856-7 was 6611. (See LIVERY.) The other essential qualification for the mayoralty is previous service as sheriff. The aldermen hold office for life. They are elected one for each of the 26 divisions or wards of the city, and all resident freemen are entitled to vote in the election for their ward, whether they are livery-men or not. Each alderman appoints one deputy, and in some cases two, for his ward.

The members of common council are chosen annually by the rate-payers of the various wards, but members are for the most part re-elected. As shown in the following table, the several wards differ very materially in extent, and so does the number of their representatives in common council:—

Account showing the Number of Common Councilmen returned by each of the 26 Wards of the City of London.

Wards	Common Councilmen.	Wards.	Common Councilmen.
Aldersgate	8	Cripplegate Within	108
Aldgate	8	and Without	16
Bassishaw	4	Dowgate	6
Billingsgate	8	Farringdon Within...	14
Bishopsgate	14	... Without...	16
Bread Street	8	Langbourn...	8
Bridge Within	8	Lime Street	4
Bridge Without	Nil	Portoken	8
Broad Street	8	Queenhithe	6
Candlewick	6	Tower	8
Castle Baynard	8	Vintry	6
Cheap	8	Walbrook.....	6
Coleman Street	8		
Cordwainers	6		206
Cornhill	6	Aldermen.....	26
Forward ...	108	Total.....	232

The ward of Bridge Without is a sinecure reserved for the senior alderman, as there have been no inhabitants in it since the demolition of Old London Bridge. The civic deliberative assembly meeting in Guildhall consists of 232 members, of which his lordship is *ex-officio* president. The law officers of the corporation are the recorder and common serjeant, both barristers, who have seats in this assembly, but no vote. The sheriffs are chosen annually on Midsummer-Day by the livery, and are executive officers for the county of Middlesex as well as the city of London.

The chamberlain is chosen annually by the livery, but the office is virtually one for life. He has the care of the city revenues. Besides, there are the city remembrancer, solicitor, town-clerk, comptroller, and many inferior officers, most of whom are chosen by the court of common council.

The dignity and power of the lord mayor is great. He is the representative of royalty in the civil government of

the city, chief commissioner of its lieutenancy, conservator of the River Thames, and on the demise of a sovereign he becomes *pro tem.* a member of the privy council. To maintain the fame of the city for hospitality, an allowance of L.8000 per annum is made to his lordship, with the use of the Mansion House, furniture, carriages, &c. To generous mayors this sum is insufficient, while the parsimonious profit by the undertaking. But municipal honours are not now, as in the olden time, the pride and ambition of the first merchants and bankers of the city, and from various causes all city men of the highest standing studiously avoid any distinction of this kind.

The 9th of November, when the lord mayor enters into office is kept as a partial holiday in the city. He then proceeds in state to Westminster Hall, where he is duly sworn, and in the evening he gives a banquet in Guildhall to the great officers of state, judges, foreign ambassadors, city functionaries, &c.

The report of the commissioners appointed to inquire into the state of the Corporation of London, presented to Parliament in 1854, gives an account of the revenue and expenditure of the city for 1852, from which it appears that the former amounted to L.551,971, 5s. 4d., and the latter to L.403,983, 1s. 2d., leaving a surplus of L.147,988; but of this L.127,710 was payable to the government office of works, for metropolitan improvements beyond the limits of the city. The report alluded to recommends some radical changes in the constitution of the corporation, and considerable abridgment of its privileges. Already bills, adopting in great measure the suggestions of the commissioners, have been brought into Parliament, and will most likely ere long pass into law.

Neither the Mansion House nor the Guildhall is remarkable for architectural beauty, though both of them are large buildings. The former was erected in 1740, and the latter in 1789, on the site of a previous Hall built in 1411.

The following are three of the chief items of the city revenue in the year 1855:—

Duties on coals brought to the metropolis.....	L.135,154
Police rates.....	56,505
Sewer rates.....	75,764

Intimately connected with the corporation are the various guilds or companies composed of livery-men, and whose functions in civic elections have been already noticed. Of these companies there are upwards of 80, of which 39 have halls, the rest meeting in Guildhall or in taverns.

In Stow's time there were but 63, and of these there were 12,—

The Mercers,	The Merchant Tailors,
... Grocers,	... Haberdashers,
... Drapers,	... Salters,
... Fishmongers,	... Ironmongers,
... Goldsmiths,	... Vintners, and
... Skinners,	... Clothworkers.

—called by him “honourable companies, out of which the lord maier is to be chosen yearely, because those of inferiour ranke are not capable of such dignitie.” This restriction no longer exists, but the twelve companies still maintain a certain pre-eminence, and are called the “great companies.” Some of these are possessed of large property; the goldsmiths, mercers, grocers, fishmongers, merchant tailors, &c., having noble halls where they dispense the most princely hospitality. The goldsmiths (the richest of all) existed as early as 1180, but were not chartered till 1327, and were long the chief bankers of London. At present all articles of gold and silver must be assayed and marked by this company. Their new hall, on the site of the former one in Foster Lane, is classic in style, and of noble proportions, but hidden by neighbouring houses. The others of most mark are Fishmongers’ Hall at the corner of London Bridge; Mercers’ Hall in

London. Cheapside; Grocers' Hall in Bank Buildings; Merchant Tailors' Hall in Threadneedle Street, &c., &c.

Police. The police force, in its present form, was established in 1829. There are in all thirteen police courts in the metropolis, of which eleven are under the superintendence of the Home Secretary, and two under that of the city corporation; justice being dispensed in the former by stipendiary magistrates, and in the latter by the mayor and aldermen. London is indebted for its present efficient police force, as for many other advantages, to Sir Robert Peel. There are in all upwards of 128 city and metropolitan police stations. The following table will show the distribution of the police force between the city and other parts of London:—

Return showing the Strength of the Police Force employed in the Metropolis in 1856, distinguishing those employed by the Commissioners of Police, and those employed by the Corporation of the City of London:—

Police.	Total Number of Men.	Average Number on Day Duty.	Average Number on Night Duty.
Force acting under Commissioners of Police, consisting of 18 divisions (A to V and Thames).....	5817	2272	3545
Force under the Corporation of the City of London.....	589	340	249
Total.....	6406	2612	3794

Debtors' prisons.

The prisons for debtors in the metropolis are three in number,—the Queen's Prison and Horsemonger Lane Gaol in Southwark, and Whitecross Street Prison in the City. The Queen's Prison contains 220 rooms, but from changes in the law it is now comparatively little used. Formerly, debtors imprisoned here were allowed to purchase the right to live within the rules or liberties of the prison, which extended for a considerable distance around its walls. This system was abolished by 5th and 6th Vict., c. 22.

The numbers of prisoners for debt in two of the metropolitan prisons during the year ended 25th March 1856 were:—

Prisons.	Prisoners.
Queen's Prison	400
Whitecross Street Prison	2358
Total.....	2758

Criminal prisons.

Of prisons for criminals there are twelve within the bounds of the metropolis. The first and most noted is Newgate Prison in the Old Bailey, the common gaol for London and Middlesex. The old gaol was burned by a mob in 1780, but a new one having been partially built at that period, it was soon completed. The number of prisoners varies from 300 to 950, though there is not proper accommodation for above 480. In front of this prison sentences of death are carried into effect for capital crimes committed in London and Middlesex.

Under the management of the directors of government convict prisons are the four following:—

Millbank Prison, to accommodate	1100 males and 180 females.
Pentonville	560 males.
Brixton	650 females.
Fulham Refuge	180 females.

Besides these there are—

The House of Correction at Holloway, a new establishment, calculated to hold.....	420
Cold Bath Fields Prison, near Gray's Inn Lane	1398
The House of Correction in Tothill Fields, Westminster ...	900

House of Detention at Clerkenwell	331
Criminal side of Horsemonger Lane Gaol.....	364
Surrey County Gaol, Wandsworth Common.....	708
Borough Compter, in Mill Street.	

London.

The following is an account of the number of persons imprisoned in each of the principal prisons during the year ended 25th March 1856:—

Table showing the Number of Prisoners confined in the various Metropolitan Gaols and Houses of Detention for Criminals, and the Mortality therein, in the Year ended 25th March 1856.

Gaols, &c.	Numbers confined.	Deaths.
Newgate Prison	2,072	1
Holloway House of Correction	2,242	2
Cold Bath Fields Prison	8,113	28
Westminster House of Correction	7,980	11
Clerkenwell do.....	11,418	1 (suicide)
Millbank Prison.....	2,093	11
Pentonville Prison.....	1,032	6
*Horsemonger Lane Gaol	3,511	1
Total.....	38,461	61

* This prison includes debtors.

The tendency within the last twenty years has been to suppress prisons in the crowded parts of the metropolis; and in this way London has got rid of the Fleet, Marshalsea, and Giltspur Street Prisons; and a fourth—the Bridewell—has fallen into disuse.

There are 71 main sewers, and about 1000 miles of sewers in the metropolis, and the same extent of house or minor drains. In 1854 there were 347 miles of pipe sewers alone, draining about 27,000 houses. But large as this amount of sewerage appears to be, it is still far from being adequate to secure the comfort of the inhabitants, and cesspools and such like nuisances still exist to a considerable extent. The sewers of "The City" are managed by the City Commissioners of Sewers; while the superintendence of the sewers and the gradual extension of a proper system of drainage to every other part of the metropolis has been entrusted to the New Metropolitan Board of Works established in 1855. It is seriously proposed to divert the whole drainage of London from the Thames, to carry it off in a monster sewer, and to throw it into the sea.

Owing to the overcrowded and offensive state of many of the metropolitan churchyards, the necessity for other receptacles for the dead has long been apparent. The consternation produced in London by the late visitations of cholera gave rise to the Metropolis Burials Act and the appointment of inspectors of burial-grounds. All such as are, from time to time, considered dangerous or unwholesome are now, by order in council, closed against funerals. The number of cemeteries in the suburbs of London has constantly increased of late years. Many of these cemeteries are prettily situated, such as those at Highgate and Norwood; and most of them are laid out with great taste. The others of most importance are,—the Brompton Cemetery (the property of government); Kensall Green, on the Harrow Road, formed in 1832, and the property of a joint-stock company; and Abney Park, Stoke Newington, and Nunhead cemeteries. The London Necropolis Company have also a cemetery at Woking, whither funerals are conveyed by railway. It is doubtful, however, whether private companies can safely be trusted with the management of these concerns, as their pecuniary interests are so much at variance with the promotion of public health. It would therefore be sound policy on the part of the govern-

London. ment to take these establishments into its own management, and suppress all private speculations of the kind.

Insurance against fire. It is calculated that, on the average, the annual number of destructive fires in this city amounts to 665; and hence the system of insurance against fire is very general. There are in London alone forty-nine offices for effecting this species of insurance; and the chief insurance companies maintain a fire-engine establishment at twenty-two different stations throughout the metropolis. As already mentioned, too, there are fire-plugs in every street for the supply of water for the engines, and fire-escapes for saving life are kept ready at convenient spots throughout the metropolis.

Fire-engines.

The troops usually kept in London consist of two of the three regiments of Life-Guards and Horse-Guards, and 5 battalions of Foot-Guards, numbering in all 4860; and there is barrack accommodation for 132 officers and 4845 men. The principal barracks for the Foot-Guards are the Wellington Barracks in Bird Cage Walk, the barracks in the Tower, at Charing-Cross, Portman Street Portman Square, and St John's Wood; the chief cavalry barracks being situated in Knightsbridge, Hyde Park, and Albany Street, Regent's Park. A volunteer corps, called the Royal Artillery Company, and composed of citizens, is well maintained, and their training-ground lies near the City Road.

As may be seen from the table annexed, the metropolis returns 16 members to parliament; Marylebone, Finsbury, Tower Hamlets, and Lambeth, having acquired their right under the Reform Act. The inhabitants of certain districts of London, such as Chelsea, Kensington, Brompton, Notting Hill, &c., which are not included in any of the metropolitan cities or boroughs, form part of the constituency of the county of Middlesex. It has been more than once proposed to constitute Chelsea, Kensington, &c., a parliamentary borough, with the right of returning two members; and from their growing importance, it is likely that this proposition will ultimately be carried out.

Account of the number of Representatives allotted to each of the Parliamentary Cities and Boroughs in the Metropolis, and the Number of Electors Registered in each in 1857.

Cities and Boroughs.	Members.	Registered Electors.
London (City of).....	4	19,115
Westminster (City of)...	2	13,182
Marylebone (Borough)	2	20,851
Finsbury,* do.....	2	20,025
Tower Hamlets, do.....	2	27,980
Southwark, do.....	2	10,170
Lambeth,* do.....	2	18,131
Total.....	16	129,454

* The numbers of electors for Finsbury and Lambeth are applicable to 1852.

Greenwich, which is now an outpost of London, also returns two members.

Internal and external communication.

Looking at the map of London, the River Thames attracts the eye as forming one great means of metropolitan internal communication; and the steamers which ply from the east to the west end every five minutes during the day, materially relieve the crowded streets from what would otherwise be an intolerable pressure.

Railways.

The shipping of London, one of its greatest means of communication, has already been noticed.

The great railways having termini in London are,—the North-Western, Great Western, South-Western, South-

Eastern, Eastern Counties, and Great Northern, and these afford means of reaching all parts of the empire with wonderful speed and comfort, and at moderate fares. There are also smaller lines more exclusively for the convenience of Londoners, such as those to Greenwich, Blackwall, Hampton Court, Windsor, &c.

London.

Street communication.

There are at present (1857) in London 4312 hackney cabs, and 1019 omnibuses, for the conveyance of persons from any part of the metropolis to another. The cabs, though not what they should be, and still inferior in comfort and cleanliness to those of other large cities, have been much improved since placed under the more immediate surveillance of the police. They convey two persons, with a moderate allowance of luggage, at the rate of 6d. per mile, within a radius of 4 miles from Charing Cross; while by omnibuses one may travel half-a-dozen miles for 6d., or even less. The extent to which the latter are patronized may be estimated from the weekly traffic receipts of the General Omnibus Company (the chief proprietors of these vehicles), which amounted, in the week ended 7th March 1857, to L.10,818, 15s.

The great street thoroughfares are about eight in number, one half running from E. to W., parallel to, or following to some extent the sinuosities of the river, and the rest tending from N. to S., and cutting the others nearly at right angles. Of the former, the most important are,—1st, That running from the Tower through Eastcheap, Cannon Street, Fleet Street, and Strand, and either by Drury Lane and Long Acre to Piccadilly and Kensington, or by Whitehall and Victoria Street to Pimlico; and 2d, That leading from Mile-end through Whitechapel, Cheapside, Newgate Street, Holborn, and Oxford Street, to Bayswater. Of those running from N. to S. may be distinguished,—1st, That from Kingsland Road through Shoreditch and Bishopsgate Street, by London Bridge and High Street, Borough, to the Bricklayers' Arms; and 2d, That from Kentish Town Road by High Street, Camden Town, the Hampstead Road, and Tottenham Court Road or Gower Street, through Bow Street, and by Waterloo Bridge and Waterloo Road to the Elephant and Castle.

The Regent, and Grand Junction Canals, besides serving as the means of internal navigation to the Irish Channel, are most useful (as are also, on a smaller scale, the Surrey, Grosvenor, and Kensington Canals) in conveying coals and such heavy goods into the heart and outskirts of the metropolis. The facility of postal communication is elsewhere noticed.

The Electric Telegraph Company have twenty stations in different parts of London; and at charges varying from 1s. 6d. to 5s. and upwards, convey messages to almost all the civilized parts of the old hemisphere, and measures are in progress for completing communication of this kind with America.

The fate of London has often given rise to prophetic speculations; and an eminent historian of the present day has shadowed forth its ruin at a somewhat distant period. But though it has increased enormously within the last century, its increased facility of communication, and advance in science, have been in a greater ratio. We may therefore safely quote the words of David Hume as applicable to the London of the present day. Speaking of its enormous and increasing size, he says,¹—"Some men are apprehensive of the consequence. For my own part, I cannot help thinking, that though the head is undoubtedly too large for the body, yet that great city is so happily situated, that its excessive bulk causes less inconvenience than even a smaller capital to a greater kingdom." (H. C. R.)

¹ Essay on Public Credit.

London
||
London-
derry.

LONDON, a town of Canada West, capital of Middlesex county, is situate on the left bank of the Thames, an affluent of Lake St Clair, 115 miles S.W. of Toronto. It stands in the centre of the great peninsula which divides Lakes Huron and Erie; and is connected by railway with Detroit, Toronto, Montreal, and Quebec. The town was laid out in 1826, and since then it has risen rapidly into importance. In 1844 and 1845 it suffered severely from fires, which consumed at different times the Episcopal church and many of the houses. These, however, were rebuilt; the former in greater elegance, the latter on a more commodious and substantial plan. In 1855 London contained several fine buildings, such as the city hall, erected at a cost of £15,000; a market-house, and 12 churches, belonging to the Episcopalian, Roman Catholic, Wesleyan, and other denominations. Its schools also fully supply the wants of the community, and are well attended. Iron-casting is carried on with considerable success, while coal is comparatively plentiful. The chief trade of the town, however, is in the grain of the county, which is reputed one of the most fertile in Upper Canada. Pop. (1852) 7000, (1855) about 13,000.

LONDON, *New*, a seaport-town of the United States of N. America, New London county, Connecticut, on the W. bank of the Thames estuary, 3 miles from the sea, and 120 miles E.N.E. of New York by railway; N. Lat. (of light-house) 41. 18. 57, W. Long. 72. 5. 4. It is situate on an acclivity which rises from the waterside, and attains a considerable elevation at the back of the town. The streets are not so regularly laid out here as in most American towns, owing to the inequality of the ground, which rests on a granite formation. Much, however, has been done of late to level the surface. The chief public edifices are,—the custom-house, a handsome granite building near the river, the court-house, and numerous churches belonging to the various denominations, besides public and private schools. The harbour of New London is one of the best in the Union, being 3 miles in length, with 5 fathoms of water, and is seldom obstructed with ice during winter. It is protected from the ocean by Fisher's Island. The great trade of the port is connected with the whale fishery, which is carried on yearly in a number of vessels, having an aggregate burden of 16,000 tons. In 1849, 1949 barrels of sperm oil arrived here, besides 38,030 barrels of common whale oil, and 2688 cwts. of whalebone. The coasting trade and cod fishery are carried on here with much vigour and success; while ship-building and machine-making are also on the increase. The town was settled in 1644, and a large part of it was burned by the British under Benedict Arnold, in September 1781. Pop. (1840) 5519, (1850) 8991, (1853) about 10,000.

LONDONDERRY, a maritime county in the province of Ulster, in Ireland, bounded on the N. by the Atlantic, on the E. by the county of Antrim, on the S. by that of Tyrone, and on the W. by Donegal and Lough Foyle. Its greatest length is from the point of Magilligan, at the entrance of Lough Foyle, to Cookstown, a distance of 52 miles; its greatest breadth, from the western point of the liberties of Londonderry to Vow Ferry, on the Bann, is 44 miles. It extends over a surface of 810 square miles, or 518,595 acres, of which 318,282 are arable, 180,709 uncultivated, 7718 in plantations, 1559 in towns, and 10,327 under water. The uncultivated pasture land of this county is chiefly situate in elevations exceeding 800 feet above the sea. Of the entire quantity, it is probable that about 50,000 acres may be improved for cultivation, 60,000 may be drained for pasture, and 71,000 may be considered as unimprovable, consisting of the tops of the highest ridges of mountains, and the sands of Magilligan.

According to Ptolemy, the tribe of the Robogdii were located here. Afterwards it was the territory of the O'Cahans,

who were feudatories of the great O'Neil family. After the confiscation of O'Neil's princely estate, in consequence of his abrupt flight into Spain at the commencement of the reign of James I., this county was offered to the city of London on certain conditions. The city accepted the grant of the towns of Derry and Coleraine, and the whole country betwixt them, which is above 20 miles in length, bounded by the sea on the N., the river Bann on the E., and the river Derry, or Lough Foyle, on the W. The common council appointed a special company for the management of the affairs of the plantation, afterwards well known under the name of the Irish Society, and retaining in its possession the houses of Londonderry and Coleraine, the lands attached thereto, and the woods, ferries, and fisheries. The remainder of the grant was in 1613 divided into twelve lots, and balloted for by the great London companies, viz., the drapers, salters, vintners, mercers, ironmongers, merchant tailors, clothworkers, haberdashers, fishmongers, grocers, goldsmiths, and skippers. The county is now divided into the baronies of Coleraine, Kenaught, Loughinsholin, and Tirkeeran, together with the liberties of Londonderry and Coleraine, which have separate jurisdictions. These greater divisions are subdivided into forty-three parishes, chiefly in the diocese of Derry.

The diocese of Derry is much larger, both as to number of parishes and extent of surface, than the county, comprehending, besides the parishes within the civil boundary, ten in Donegal, eleven in Tyrone, and part of a parish in Antrim. By a curious anomaly, the ecclesiastical jurisdiction of the parishes in the liberties of Coleraine belongs to the Bishop of Down and Connor. The seat of the see is in the city of Derry, where is the cathedral, a building in inferior Gothic style, erected in 1633. The chapter consists of a dean, an archdeacon, and three prebendaries.

The neighbourhood of the great Western Ocean, and the height of the mountain ranges, may account for the fall of a considerable quantity of rain; yet Mr Sampson in his survey of the county states the mean annual depth of rain as only 31 inches, and in the ordnance survey of the parish of Templemore it is stated at 34.2 inches.

The surface of the county presents an appearance of valleys separated from each other by ridges of rugged but not very elevated mountains, and expanding as they approach the coast into alluvial plains. The most elevated of the mountains are,—Sawel, 2236 feet high; White Mountain, 1996 feet; Slieve Gallen, 1730 feet; Cairntogher, 1521 feet; Donald's Hill, 1318 feet; Benyevanagh, 1262 feet; and Legavannon, 1269 feet.

The principal river is the Roe, which, receiving as it flows in a northerly direction the tributary streams of the Owenbeg, Owenmore, Gelvan, Castle, and Curley, discharges itself into Lough Foyle, below Newtown-Limavady. The mud deposited near its mouth forms shifting banks, which prevent it from being a useful port for small craft. The Faughan rises in the S., and discharges itself into Lough Foyle, nearly opposite Culmore Fort. The Moyola takes a south-eastern course, and falls into Lough Neagh. A small portion only of the Foyle belongs to the county. It is navigable for vessels of large burden as far as the city of Londonderry, and thence to Lifford in Donegal for lighters of 20 tons. The Upper Bann, from Lough Neagh, forms the eastern boundary until it approaches Coleraine, where it separates the barony from the liberties of the town. The navigation of this river is impeded by shoals, which form a dangerous bar.

The valleys formed by these rivers, and their subordinate branches, are called *slacks*. The most beautiful is that of Fin-Glen. On the western side of the ridge of Benyevanagh there is a shaking quag, named the Gray Lough, which spreads over many acres. Cattle can pass freely through it in summer, yet at every step the soil yields

London-
derry.

London-
derry.

to the pressure, communicating an undulating motion all around. The surface is broken in every direction by pits full of water of unknown depth, and all invariably rectangular parallelograms, very much resembling tan-pits. The only lake is Lough Finn, situated in the confines of Tyrone; it is of very inconsiderable dimensions. Lough Neagh touches the county over about 6 miles of its south-eastern boundary. The small port of Ballyronan, in the N.W. angle of the lough, affords accommodation for sloops of 60 tons to load and unload. The inlet of Lough Foyle forms the principal part of the western boundary. Having a narrow entrance, but with 10 fathoms of water, between Culmore Fort and Magilligan Point, it expands itself at high water into a gulf of 15 miles in length and 7 in breadth, with a channel 14 fathoms deep at low water, but very narrow, and therefore of difficult navigation.

The soil in the northern part, along the sea-coast, is a stiff and reddish clay, interspersed with knolls of basalt, and resting on a substratum of white limestone, which occasionally appears on the surface. Near the mouth of the Roe is an extensive tract of a marly nature, formed of layers of clay and shells, alternating to a depth of several feet. Fossil shells are frequently found in the ditches. The lands lying between the loamy soil in the low grounds and the higher wastes are either of a blue clay with fragments of quartz, slate, and a shallow covering of peat moss, or a shingle of slate interspersed with red ochreous sand, or with gravel and loam. Above the lime is the region of the trap, and the soil is generally without clay, being merely composed of the softer parts of this ochreous sand, producing little but potatoes and straw. Yet its summits are admirable as sheep walks; for, if the immediate substratum be of the fossil known by the name of zeolite trap, the soil is fertile and the herbage sweet, presenting an elegant carpeting of shamrock, daisy, butter-cup, and plantain, which is eagerly browsed on by sheep.

The valley of the Roe divides the county into two districts, totally different in respect to their geological character. On the W. lies the territory of clay slate, on the E. that of basalt. The prevalent species of slate is a kind of flag-rock or micaceous clay slate, next to which in quantity is a laminated flag, the dip of which is generally N.W. The great mountain of Sawel is composed of several varieties of this rock, surmounted towards the summit by amorphous whinstone, interspersed with veins of quartz. Slieve Gallen is also a mass of trap, resting upon granite, which emerges from beneath in various places. Limestone may be found everywhere, from the sea to Benbradagh. The most remarkable cavern on the coast is in the white limestone; it is very appropriately called the Robber's Cave, having at one time been the asylum of formidable banditti. A species of blue limestone has been used for various architectural purposes. Sandstone is universally found below the basalt, and is occasionally intermingled with slate. A species of it, of a bright tawny colour, is raised in large quantities near Dungiven. Many of the principal buildings are constructed of it. Iron is found in great abundance, as bog ore. To the abundance of this metal in the peat moss is to be attributed the red colour of the ashes, which are so heavy as to keep in heaps even in a breeze of wind. Copper and lead, in small veins, have been discovered. Boate states that pure gold had been found in a rivulet which discharges itself into Lough Neagh; but the fact has not been substantiated by subsequent discoveries, further than that some specimens of quartz have been observed to contain thin laminæ of that metal. Quartz and hornstone are common in all parts. The latter sometimes exhibits marine impressions, the quartz never. In all the mountains composed of slate with pyrites the streamlets show strong indications of iron,—to such a degree, indeed, that in some places the water is not fit for drinking.

VOL. XIII.

London-
derry.

The treatment of arable ground differs little from that generally practised throughout the province. The principal crops are oats and potatoes; the implements, the Scotch and Irish ploughs; the manures, sea-weed, and composts of which it forms a part, near the coast, and lime and turf-mould in the interior. The shell banks of Lough Foyle also furnish valuable manure. When the tide is out these banks form extensive flats, which are firm enough to be walked on without inconvenience, and are resorted to by numerous boats for loads of shells, which are all of recent species, and the supply is apparently inexhaustible. "They are particularly useful in bringing bad lands into cultivation, and in ameliorating stiff wet clays, deficient in calcareous matter, being applied at the rate of from thirty to sixty barrels per acre. They are preferred to lime as warming and bristling the land." In Magilligan the mossy sands are alternately ploughed and laid up in meadow.

The farms in this county are generally small; out of 17,000 holdings exceeding one acre in extent, about 13,500 are of less than 30 acres, 2100 between 30 and 50 acres, and 1100 between 50 and 100 acres. The extent of land under each description of crop in 1855 and 1856 was:—

	1855. Acres.	1856. Acres.
Wheat.....	3,201	5,424
Oats.....	91,990	87,017
Barley, Bere, Rye, Beans and Pease...	2,084	2,368
Potatoes.....	31,983	35,464
Turnips.....	11,451	10,301
Other Green Crops.....	1,454	1,545
Flax.....	11,795	13,959
Meadow and Clover.....	20,379	22,310
Total.....	174,337	178,388

The florin grass springs up luxuriantly here. Amongst the more uncommon species of grasses may be mentioned the *Parnassia palustris*, commonly called crottel,—in Irish croutail.

The total quantity of live stock in the county in 1855 and 1856 was:—

	1855. No.	1856. No.
Horses.....	20,331	21,254
Cattle.....	102,185	101,556
Sheep.....	23,888	32,129
Pigs.....	22,828	23,679

There are no great herds of goats in the mountains, but a few are found in many of the habitations of the cottiers. Magilligan contains a very large rabbit-warren, extending over 1500 acres. The poultry are numerous, and flocks of geese are fed in summer on the vetches and tares which abound in the bottoms, in autumn on the stubble, and in winter on the potato-ridge. The county was once remarkable for the quantity of honey it produced; latterly the produce has decreased.

The linen manufacture is the staple here, and contributes greatly to the comfortable support of the population. The yarn and linen are generally of a coarser staple than in the neighbouring county of Antrim. Sacking is made of the tow-yarn. Potteries, in which the coarser kinds of earthenware are manufactured, are carried on in some places. There are several large distilleries and breweries, and some salt-works. One of the most productive salmon fisheries in Ireland is on the Bann, near Coleraine.

The most remarkable relic of ancient fortification is the Giant's Sconce, or Ring, a remarkable remnant of pagan times, situate in the pass between Drumbo and Largantea. It formed a circular space of about 600 feet in diameter, on an isolated knoll of basalt, difficult of access on all sides but the N.E., where art has supplied the deficiency by a wall of massive masonry. The interior was hollowed, as if for a receptacle for men and stores; whilst a covered way, admitting only one person in a stooping posture to pass at

London-
derry.

a time, surrounded the whole. Several cromlechs are still in existence, some of them surrounded by a circle of upright pillars, somewhat like Stonehenge. The most remarkable is that at Slacht Manus. Cairns are too numerous to admit of special notice. Danish forts are sometimes exposed. Sepulchral pillars are numerous, and one peculiarly remarkable stands near Dungiven. Artificial caverns, evidently constructed for the concealment of men and property, are frequently discovered. They are rudely built of stone, without cement; and flags or long stones form the roof. They consist of narrow galleries, some at right angles with the main entrance, others parallel to it. The entrance is usually concealed by a rock or grassy sod. Castles of acknowledged Irish erection are few. That of Carrickreagh is looked upon as amongst the most ancient. Near Ballyraghran was another. Both are said to have been residences of the family of the M'Quillans. Pieces of pit-coal, found in the cement of the walls, lead to the opinion that the operations of miners were practised in those remote ages. Some of the castellated mansions of the first English settlers, with their *bawns*, are still in a state of preservation; as at Killolod, Dungiven, Salterstown, and Muff.

The most ancient monastic building was the abbey of Derry, founded by S. Columba in the sixth century, and on the site of which the present cathedral stands. At Coleraine were two monasteries, one of Dominicans, the other of regular canons. At Camus, on the Bann, was a very celebrated monastic structure, attributed to St Comgal. The only remains of it at present existing are the fort, with a pillar curiously carved. The remains of the abbey of Dungiven are the most interesting in the county. It was the burial-place of the O'Cahans several of whose tombs have resisted the attacks of time. The principal monument is that of one of the chieftains, named Cooley-nagal. There is a tower at the north-west side of the building, and a sepulchral pillar placed on an artificial mount. A smaller tumulus in the vicinity, when opened, was found to contain an urn of earthenware with bones. The urn was surrounded with white stones. Other tumuli, when examined, exhibit similar results.

The number of pupils attending each description of school during the week ending 15th April 1851 was:—

Schools.	No. of Schools.	Scholars.		
		Male.	Female.	Total.
National.....	145	3657	3153	6,810
Church Education.....	33	652	627	1,279
London Corporations.....	24	645	621	1,266
Diocesan.....	1	74	...	74
Endowed.....	6	188	125	313

Total.....	338	8445	6774	15,219

The great London companies have always afforded marked encouragement to the education of the people, and no consideration as to the religion of the children is allowed to interfere with their bounty.

The population has increased progressively from the earliest period at which any probable estimate of its amount was made until the last two decennial periods:—

Year.	Authority.	Population.
1760.....	De Burgho.....	46,182
1792.....	Beaufort.....	125,000
1813.....	Parliamentary census.....	186,181
1821.....	Ditto.....	193,869
1831.....	Ditto.....	222,012
1841.....	Ditto.....	222,174
1851.....	Ditto.....	191,868

London-
derry.

The last of these estimates gives an average of 237 inhabitants to each square mile. The county is represented in the imperial parliament by two members for the county at large, and one for each of the boroughs of Londonderry and Coleraine.

LONDONDERRY, the capital of the above county, stands on the W. side of the River Foyle, near to its junction with the lough, spreading itself over the summit and sides of a hill which here projects into the river, and which was once covered with oak trees, whence the place derived the name of Derry Calgach, "the eminence covered with oaks," which it still partially retains. "The situation of Londonderry is," says Inglis, "the finest of any town or city in Ireland. Indeed, with the exception of Edinburgh, I do not know any town in the United Kingdom so well situate as Londonderry." Its monastery first drew inhabitants hither. The town was entirely ecclesiastical, consisting almost exclusively of churches and the dwellings of the clergy and their dependents. The English government, after having been baffled in several attempts to plant a garrison here during the war against the Earl of Tyrone, at length succeeded, in 1600, in gaining possession of the place, and securing it against any efforts of the Irish to dislodge them. It was surrounded with a substantial wall, strengthened with bastions, and had four main streets diverging at right angles from a point on the summit of the hill, now called the Diamond, to a gate at the other extremity of each. The strength of these fortifications was tested in the subsequent wars of 1642 and 1688, in each of which the town maintained a successful stand against its besiegers. After a lapse of more than two centuries, the walls still retain, in most parts, their original form and character. The external ditch, indeed, has disappeared. The gates have been rebuilt in a more elegant style of architecture, and two new ones have been added. One bastion has been removed to make way for a butter-market, and another has been appropriated as the site of a pillar commemorative of the military services of the Rev. George Walker during the memorable siege which lasted 105 days; it commenced on the 18th of April 1689, and was raised on the 1st of August following. The cathedral stands within the walls, on the most elevated portion of the hill of Derry. It consists of a nave, divided into a central and lateral aisle, separated by pointed arches. There are four Presbyterian, one Independent, and two Methodist meeting-houses; there are also two Roman Catholic chapels and a large Roman Catholic cathedral. The corporation hall stands in the centre of the Diamond. It is surrounded by a colonnade, with embattled parapet; and the same kind of military ornament surrounds its roof. The other public buildings are,—the court-house, the lunatic asylum, the poor-house, the gaol, the custom-house, the linen-hall, the public library and news-room, the barrack, and the magazine. The bridge is the peculiar boast of Derry. It is built of wood, and extends in length 1068 feet by a breadth of 40. A turning bridge, near the centre, admits a free navigation to vessels going up the river. Walker's Testimonial is a pillar of the Roman Doric order—erected in 1828 by public subscription—surmounted by a statue of that celebrated individual, represented as dressed in canonicals, and armed with the Bible and the sword. Its height is 82 feet including its base; the statue is 9 feet high.

The municipal jurisdiction extends over a space of 3 miles in every direction from the centre of the city. The

Long
Island
||
Long,
Roger.

government is vested in a mayor, six aldermen, and eighteen councillors. The income of the corporation, amounting to L.12,000 per annum, arises from tolls on the bridges, tolls on the market, rents of land and shambles, and tonnage and quayage.

The progress of commerce may be estimated from the custom-house receipts at different periods:—

Years.	L.	Years.	L.
1830	74,856	1853.....	123,225
1849	104,991	1854.....	114,526
1851.....	108,194	1855.....	120,561

The shipping of the port of Derry in 1760 consisted of 67 sail, of from 30 to 350 tons. At the conclusion of the last century, the tonnage registered at the port was about 3000, which has since increased to upwards of 25,000 tons. In 1855, 1224 vessels, of 214,990 tons, entered inwards; and 759 vessels, of 171,448 tons, cleared outwards.

The population of the city in 1841 was 15,196; and in 1851, 19,399. (H. S.—R.)

LONG ISLAND, a long narrow island off the E. coast of the United States of N. America, forming part of New York state, and separated from the mainland at its western extremity by two channels, called the Narrows and the East River, the former $1\frac{1}{2}$ mile, the latter $\frac{3}{4}$ of a mile in width. It stretches from W.S.W. to E.N.E., between N. Lat. 40. 33. and 41. 6., and W. Long. 71. 50. and 74. 4., being 115 miles long, by from 12 to 20 miles broad, and containing an area of about 1448 square miles. A low range of hills extends from one extremity of the island to the other, exhibiting on the northern slope an irregular and broken surface, while on the S. the ridge declines more gently to the Atlantic. There are no large streams; and the want of water-power is much felt in the island. The soil is of a light sandy character, generally sterile on the southern coast, but productive at the western extremity, in King's and Queen's County. The coasts are much indented, forming numerous large lagoons on the southern coast, and an extensive inlet at the eastern extremity, which almost severs the island in two. A railroad, one of the first constructed in the state, and originally intended to accelerate the traffic between New York and Boston, traverses it from W. to E. Communication is kept up with the mainland by means of steam ferries at Brooklyn, Fort Hamilton, &c. The island is divided into the three counties of King's, Queen's, and Suffolk. Pop. (1850) 212,637, (1854) about 260,000. (See NEW YORK.)

LONG ISLAND, or *Yuna*. See **BAHAMAS**.

LONG, Loch, an arm of the sea on the W. coast of Scotland, stretching first N. then N.E. from the Firth of Clyde, and separating the counties of Argyll and Dumbarton. It is 20 miles long by from 1 to 2 miles broad. From its centre a branch loch stretches for $4\frac{1}{2}$ miles northwards into Argyllshire, called Loch Goil. The shores of both lochs are mountainous and highly picturesque.

LONG, ROGER, an astronomer, was born in Norfolk about 1680. He was educated at Pembroke Hall, Cambridge, was created a master of arts in 1704, and a doctor of divinity in 1728. He was chosen a fellow of the Royal Society, and vice-chancellor of the university in 1729, and master of Pembroke Hall in 1733. In 1749 he was elected Lowndes professor of astronomy, and in 1751 was appointed to the rectory of Bradwell, in Essex. He was also the rector of Cherryhinton, in Huntingdonshire. At his death in 1770, he bequeathed L.600 to his college. Long is best known as the inventor of a curious contrivance, at Pembroke Hall, for facilitating the study of astronomy. It is a hollow sphere 18 feet in diameter, and capable of containing thirty persons. The inner surface is covered by a map of the heavenly bodies, and represents that portion of the celestial sphere visible in Britain. The entire structure is moved by machinery. Long's chief work is a

Treatise on Astronomy, Cambridge, 1742–64, 1781, 2 vols. 4to. He also wrote a *Commencement Sermon*, 1723; a pamphlet entitled *The Rights of Churches and Colleges Defended*, 1731, 8vo; an *Answer to Dr Gally's Pamphlet on Greek Accents*, 1755; and a *Life of Mahomet*, prefixed to Oakley's *History of the Saracens*.

LONG, St John, was born at Newcastle in Limerick, in 1798. From his father, a person of versatile ingenuity, he inherited a disposition to try his hand at whatever vocation came in his way. At the age of 25, after studying painting in Dublin, he set out for London as an artist. His merit not meeting with due appreciation, he resolved to turn his hand to medicine. In 1826 he acquired great celebrity by his specific for consumption and other diseases generally regarded as incurable. After some time, he was tried for the death of a young lady, a patient, and found guilty of manslaughter. So great was his influence that no less than sixty-three persons of rank appeared in his favour. After realising a large fortune, he fell a victim to the disease which he professed to cure at the age of 36.

LONGFORD, an inland county in the north-western extremity of the province of Leinster, in Ireland, bounded on the N. by the counties of Leitrim and Cavan, on the E. and S. by Westmeath, and on the W. by Roscommon, from which it is separated by the Shannon. Excepting Carlow and Dublin, it is the smallest county in Ireland, comprising an area of 420 square miles, or 269,409 acres, of which 191,823 are arable, 58,937 uncultivated, 4610 in plantation, 364 in towns, and 13,675 are under water. The uncultivated land consists either of heathy pasture, or of flow-bog. The latter may amount to about 30,000 acres, of which about 18,000 acres are susceptible of improvement for cultivation, by a system of perfect draining, followed by a coating of from three to four inches of clay and gravel, which occur abundantly near the edges of most of the bogs. The whole might be considered capable of cultivation; but owing to the expense of conveying gravel from the edge, even by the assistance of railways, the surface cannot be coated with clay at a remunerative price at a greater distance than half a statute mile from the bog edge; but the entire extent might be advantageously drained, by which means, in a few years, coarse pasture would be produced. Including the mountain pasture and a portion of the bogs, this county contains 18,000 acres which may be reclaimed for cultivation, so as to produce corn and green crops; 38,000 acres may be improved for pasture; and 3000 acres are incapable of improvement.

The county, according to Whitaker, was peopled by the tribe of the Scoti, who spread themselves over most of the inland regions. Afterwards, under the name of the Anally, it became the principality of the O'Ferrals. In the reign of Elizabeth, it was made shire-ground, being one of the seven counties into which Connaught was then divided; but it was afterwards transferred to Leinster, of which it still continues to form a part. It is divided into the six baronies of Ardagh, Granard, Longford, Moydow, Rathcline, and Shrule, which are subdivided into twenty-six parishes, all in the diocese of Ardagh, except one, which is in that of Meath.

The diocese of Ardagh, which was founded in the fifth century, was in 1658 united with that of Kilmore, from which it was subsequently separated, and, after being for some time held alone, was united with the archdiocese of Tuam; but according to the recent ecclesiastical arrangements, it is united with the sees of Kilmore and Elphin. No traces of the cathedral are now in existence.

By much the greater part of the surface of the county is level, but in its northern angle it rises into bleak and rugged hills of no great elevation; and some hills also protrude in various parts of the plain country. The general surface,

Long,
St John.
||
Longford.

Longford. however, is of considerable elevation, the summit-level of the Royal Canal, which is within the county, being 290 feet above the level of the sea. The only rivers of any size are—the Camlin, which rises near Granard, and flows by the town of Longford into the Shannon near Tarmonbarry; and the Inny, which has its source in Lough Shillin, on the borders of Cavan, passes by the southern border of the county, through a fertile and well-peopled district, and discharges itself, after a winding course, into Lough Ree, being navigable from Ballymahon. There are several lakes within the county, but none of them of great extent. The most remarkable are Lough Gawnagh in the north, Derrylough, Lough Drum, and Lough Bannow. The fine expanse of Lough Ree, on the western side of the county, may be considered as partly belonging to it. It has in it the islets of Innisbofin, Innisclohran, and Innismacsaint. Lough Derrymacar is merely an arm of this lake. The quantity of bog in the county is considerable. Some of the bogs contain deep places, which are known by the name of swallow-holes, and throw up large quantities of water. In 1809, part of the bog near Johnstown burst away from the main body, and moved to a considerable distance, crossing in its passage the river Camlin, the channel of which it choked up, and caused all the adjoining lands to be flooded.

The northern boundary of the great limestone field of Ireland passes through this county. The line of division is marked by the Camlin as far as Longford town, and thence proceeds by Johnstown to Lough Shillin. To the north of this line the formation is of clay slate and greywacké. Isolated hills of sandstone show themselves at Slievegoldry and at Ballymahon, on both sides of the Inny. Indications of iron are abundant in the northern parts. Near Lough Gawnagh very rich iron ore has been observed. Marble of fine colour, and susceptible of a high polish, has been raised from quarries near Ledwithstown.

A great portion of the northern part of the county is of a rough, untractable quality, affording little encouragement for agricultural speculations; but all the more level districts, not covered with bog, are of good quality, the soil being mostly rich, and of easy culture.

The extent of land in the county under each description of crops in 1855 and 1856, was:—

	1855. Acres.	1856. Acres.
Wheat.....	2,253	2,847
Oats.....	38,841	36,893
Barley, Bere, Rye, Beans, and Pease...	328	497
Potatoes.....	16,258	17,262
Turnips.....	2,730	2,800
Other Green Crops.....	936	1,224
Flax.....	262	388
Meadow and Clover.....	20,156	21,036
Total.....	81,744	83,047

The manufactures are confined to those necessary to supply the limited wants of an agricultural population. The principal are linen, frieze, linsey-woolsey, for the garments of men and women, and leather for shoes and harness.

The only vestige of remote antiquity worthy of special notice is a tumulus at one end of the town of Granard, said to have been a Danish rath, and called the Moat of Granard. It is 593 feet above the level of the sea, and commands a view of six or seven surrounding counties. Though several ruins of monastic buildings may still be traced, few memorials of their history have been preserved. The island of Inchimore in Lough Gawnagh, and those of Innisbofin, Innisclohran, and Innismacsaint, in Lough Reagh, were each at some remote period the site of a religious house, now in utter ruin. The castle of Longford, once the mansion of the O'Ferrals, was taken at the commencement of the war of 1641, and the garrison slaughtered after their surrender upon terms. Rathcline, placed in a highly

romantic position near Lanesborough, was dismantled by Cromwell, and burned in the wars between William and James. The castles of Ballymahon, Barnacor, and Castlecor, were built to command passes over the Inny. Of these, the last named has suffered not only from the ravages of time, but from excavations made to discover concealed money, imagined to have been buried in its interior. The seats of the gentry are numerous. Carrickglass on the Camlin, the seat of Chief Justice Lefroy, is a fine residence; as is also Castle Forbes, the seat of the Earl of Granard; and Edgeworthstown will long be noted in the annals of British literature as the residence of the Edgeworth family. This county is also celebrated for having given birth to Oliver Goldsmith, who was born at Pallas, a village near Ballymahon.

The statements of the population at various periods, with the authorities on which they rest, are as follow:—

1760.....	De Burgho.....	25,142
1792.....	Beaufort.....	50,100
1813.....	Parliamentary return.....	95,917
1821.....	Ditto.....	107,570
1831.....	Ditto.....	112,558
1841.....	Ditto.....	115,491
1851.....	Ditto.....	82,350

The proportion of Protestants to Catholics is as one to eight, and the number of Protestant dissenters is inconsiderable. The number of schools and pupils attending them during the week ended 12th April 1851, was:—

SCHOOLS.	No. of Schools.	No. of Pupils.		
		Males.	Females.	Total.
National.....	43	1389	1160	2549
Church Education.....	13	298	284	582
Endowed.....	1	27	3	30
Boarding.....	1	30	...	30
Private.....	52	788	554	1342
Parochial.....	3	58	75	133
Free.....	4	92	101	193
Military.....	1	22	20	42
Mission.....	1	8	9	17
Workhouse.....	4	761	792	1543
Gaol.....	1	22	4	26
Total.....	124	3485	3002	6487

The county of Longford returns two members to parliament. (H. S.—R.)

LONGFORD, the county town, is situate on the River Camlin, in the midst of an extensive plain of mixed pasture, tillage, swamp, and bog land, interrupted only towards the S. by the hill of Fenighfadd, which rises to a height of 200 feet. It contains a Protestant church and a Roman Catholic chapel, a gaol, a court-house, a market-house, a union workhouse, and barracks for cavalry and infantry. It has a tolerable share of inland trade, which has been much enlarged by the extension of the line of the Royal Canal through it. Here are also extensive stores, corn mills, tan-yards, &c. Its population amounted in 1851 to 4614 souls.

LONGINUS, DIONYSIUS CASSIUS, a celebrated Greek critic, was born about A.D. 213. His name, originally Dionysius, was changed for some unknown reason; and, besides the full title given above, he was also called Dionysius Longinus, or Cassius Longinus. According to some, he was born at Palmyra; others think that his intimate knowledge of Syriac, and the fact that his uncle was a native of Emesa, in Syria, indicate that he also was born in that city. From the circumstance, however, that Longinus, in his boyhood, seems to have been under the care and tuition of his uncle Fronto, the famous teacher of rhetoric at Athens, it is most probable that he was an Athenian by birth. On Fronto's death he became his heir; and, from one of his fragmentary works preserved by Porphyry, we learn that, in his earlier years, he travelled much, and thus formed an

Longitude. intimacy with Ammonius Saccas, Origen, Plotinus, Amelios, and other philosophers. Under the instructions of the first two were imbibed his admiration for Plato, which a subsequent familiarity with the works of that philosopher confirmed; and his sympathy with the spirit of the Platonic philosophy, which he everywhere exhibits in the few of his comments on *Plato's Dialogues* that are extant. On completing his education, Longinus fixed his residence at Athens, and devoted the chief part of his time to the instruction of young men in philosophy, criticism, rhetoric, and grammar. His most distinguished pupil was Malchus, whose Syriac name Longinus has changed into the Greek synonym, Porphyry. After sojourning for a considerable period at Athens, where he composed most of his works, Longinus travelled into the East; and on being invited by Queen Zenobia of Palmyra to become her instructor in Greek literature, settled in that city. On the demise of her husband soon afterwards, the queen, assuming the reins of government, appointed Longinus one of her counsellors. In this new capacity he persuaded her to shake off the Roman yoke, and dictated, it is said, a defiant letter to the Emperor Aurelian. This zeal was ungratefully employed by Zenobia as a shield to ward off the punishment of her revolt; for, when Palmyra was captured by the Romans, A.D. 273, Longinus was delivered up and condemned to death by order of the emperor. He met his doom with firmness.

So high did Longinus stand in the estimation of his contemporaries, that Porphyry styled him "the critic;" and the phrase "*κατὰ Λογγίνον κρίναι*" meant "to judge correctly." Not less noted was his erudition, so that Eunapius called him "a living library and walking museum." Of his numerous works, both philosophical and critical, the only one extant is his dissertation *Περὶ ὑψους* (*On the Sublime*), a treatise not more remarkable for the sagacity with which its canons of criticism are framed than for the judicious taste with which the passages adduced in support of these canons are selected from the best authors. The diction of the work, moreover, is a striking example of that forcible and elevated style which he endeavours to teach. Of the philosophical character of Longinus, almost the only note we have is that from Plotinus, who says, that "he was a philologer, but no philosopher." This taunt, however, loses the greater part of its value when we consider that its author probably set up, as his ideal of philosophy, the trifling and whimsical speculations of his own age. Though a pagan, Longinus was acquainted with the sacred Scriptures. In his famous treatise he quotes, as a specimen of the sublime, the passage from Genesis,—“And God said, let there be light, and there was light.” And in one of his extant fragments he ranks Paul of Tarsus, as he styles the apostle, with Demosthenes and the celebrated orators of Greece. Emanations, too, from the spirit of Christianity can be detected in his writings.

The best editions of the treatise *On the Sublime* are those of Pearce, London, 1724, 4to; 1773, 8vo; and of Morus, Leipsic, 1769–73, 8vo. The same work, together with all the surviving fragments of his other works, was published by Toup, with notes by Ruhnken, Oxford, 1778, 1789, and 1806, 8vo; by Weiske, Leipsic, 1809, 8vo; and by Egger, Paris, 1837, 16mo. Longinus has been translated into French by Boileau; into German by Schlosser, Leipsic, 1781; and into English by Smith, 1739, 1800.

LONGITUDE. By the term *geographical longitude*, is meant an arc which measures the inclinations of two terrestrial meridional planes, one of which passes through a known place, as a place of reference, the other through any place whatever. It is sometimes also defined as the distance E. or W. along the equator, of any place from a certain meridian. The selection of a station from which the longitudes of all other places are to be reckoned is en-

tirely arbitrary; British astronomers and geographers have chosen the meridian of the Royal Observatory of Greenwich as their *first meridian*. The French and other continental nations refer the longitudes of all places to the meridian of their principal observatory.

The longitude of a place may be expressed in hours, minutes, and seconds of time, or in degrees, minutes, and seconds of space; if it be given in either, it may be translated into the other. The reason of this is, that the earth revolves on its axis from W. to E. in twenty-four mean solar hours, thereby causing the first meridian to describe during that time a space equal to 360°, and, therefore, in one hour 15°. Hence, if the plane of the first meridian pass at the present moment through the sun, then the meridian of a place 15° west of the former will pass through the sun exactly one hour after; if the place be 15° east of the first meridian, the plane of the former will pass through the sun one hour before the latter. The sun always passes the meridian of any place when highest in the heavens, i.e. at mid-day, or twelve o'clock mean solar time. Wherefore, places lying to the E. of the first meridian will have every hour earlier, but places lying to the W. of that meridian will have every hour later than it; so that if, while the meridian of one place is passing through the sun, the time be known before the meridian of another place pass through the sun, then the longitude of that place from the former is determined, the time being turned into space, at the rate of 15° to the hour. Hence, therefore, places will have E. or W. longitude, according as they lie E. or W. of Greenwich Observatory, the longitude of the meridian of which is zero.

The problem of the longitude may be reduced to this,—Given the hour by calculation at the place of observation, to find the hour at Greenwich Observatory corresponding to the same time; the difference of times gives the longitude of the place from Greenwich. The solution of this problem was attempted in very early times, dating even from the time of the ancient Egyptians, but the results obtained were very inaccurate. These results were deduced from tables of celestial phenomena calculated for a certain meridian, and then the times were compared with the times at which the same phenomena appeared at a different place; actual admeasurement was also employed. But it was not till after the invention of watches that the problem was rendered solvable. Harrison, in the eighteenth century, was the first who gave a *true* solution by a watch; but the first accurate resolution of the problem may be said to date from the discovery by Galileo of Jupiter's satellites, and his tables of their motions. The result of the problem at this period, as well as now, was, as Wolfius has expressed it, that means might be found whereby the art of navigation might be brought to its utmost pitch of perfection.

If the advantages of determining the longitude to a commercial and maritime people be considered, it will not appear surprising that princes and others should have held out high rewards for a true solution of the problem. Philip III., king of Spain, saw its value, and in 1598 offered a reward of 1000 crowns to the person who would solve it. The States of Holland imitated his example by a prize of 10,000 florins. In the year 1714, the British government offered a premium of L.20,000 for any method whereby the longitude might be determined at sea to within 30 miles; L.15,000, if the proposed method would give it to within 40 geographical miles; L.10,000, if it would determine the longitude to within 60 miles. It was also enacted, that a reward of L.5000 would be given to the inventor of any time-keeper which should enable a ship, during a voyage of six months, to keep her longitude to within 60 miles; L.7500 if within 40 miles; and L.10,000 if within 30 miles. If the method were by improved astronomical tables, the reward was to be L.5000, the tables being com-

Longitude. pared with previous observations. France also, in 1716, under the regency of the Duke of Orleans, offered a prize of 100,000 livres. In consequence of these rewards, many and various methods were proposed, the best of which, at least as respects frequency of observation and shortness of calculation, is the method of *Lunar Distances*.

Jean Werner of Nuremberg appears to be the first who proposed, in his *Ptolemy's Geography*, 1514, a method of finding the longitude by the distance between the moon and a star. The lunar method was also recommended by Oronce Finé of Briangon, in his book *De Inveniendis Longitudine*; by Gemma Frisius, in his treatise, *Structura Radii Astronomici et Geometrici*, 1545; by Kepler in his *Rudolphine Tables*; and by Christian Longomontanus in his *Astronomia Danica*, 1622. Gemma Frisius is, moreover, said to have attempted the longitude by a watch some time after 1530. Carpenter, in his *Geography*, 1635, says that the lunar method is to be ascribed to Pierre Applan, a German, born in 1495. John Baptiste Morin, in 1634, attempted to improve the lunar method, and received, in 1645, a pension of 2000 livres; but his *improvements* were useless, as Pascal declared, owing to the imperfect nature of the existing tables.

The tables of celestial observations previous to Flamsteed's time were imperfect and erroneous: those generally used were Tycho Brahe's or Kepler's, and to show that they were of little value in determining the longitude, although invaluable in other respects, it may be stated that Flamsteed's observed differed from Tycho's computed places by 5', 6', or more; and the tabulated distances of the latter differed from the observed distances of the former by 15' or 20', which would cause an error in the longitude of about 15°, or 300 leagues. Tycho's *lunar theory*, and the tables grounded on it, were in error 12' and more. The uncertainty, then, of these tables being known, as well as the paucity of astronomical observations generally, a Frenchman, named Le Sieur de St Pierre, contrived, in 1674, to get his pretensions to the discovery of the longitude brought under the notice of Charles II. of Britain and the court. Commissioners were appointed, and St Pierre's data necessary to work the problem were as follow:—(1.) The heights of two stars, and on which side of the meridian they were; (2.) The heights of the two limbs of the moon; (3.) The height of the pole; all to be given in degrees and minutes; and (4.) The year and day of observation. Flamsteed being in London at the time, was appointed, not only to act as a commissioner, but also to supply the necessary data. St Pierre, having received the data which he required, refused to work the problem, because he alleged the observations given him were feigned. Flamsteed on this wrote to the commissioners, assuring them that the observations were genuine, and at the same time stated, that the longitude could not be solved by the conditions proposed; but if the tables of celestial observations, especially those of the moon, could be rendered more accurate, then the longitude might be determined by them. On the letter being shown to Charles, his majesty was startled at the assertion of the computed places not agreeing with the observed, and said with some vehemence, he must have them observed, examined, and corrected anew for the use of his seamen. It was this simple incident which led to the formation of the Royal Observatory of Greenwich, the foundation of which was laid by Flamsteed on the 10th of August 1675; and it was in that building that Flamsteed laboured for forty-four years, under the most trying circumstances, to correct existing tables, and to commence the *British Catalogue*, one of the noblest monuments of British perseverance. So valuable were Flamsteed's observations to Newton, that they enabled him to form his *lunar theory*, which is now of such consequence in determining the longitude.

From the improvements made in watches by Huygens,

Longitude. Hooke, and others, previous to the year 1714, it was thought that the longitude would be solved by this machine. Hence, after 1714, the best artists applied themselves to the construction and improvement of watches. Henry Sully, an Englishman, but resident at Paris, tried in 1726 to determine the longitude by a *marine watch*, but without success. Julian Leroy, one of his pupils, would appear to lay claim to priority of invention; but it has never been disputed that the honour of solving the difficult problem of the longitude by means of a watch belongs wholly to Harrison. This ingenious workman began, at a very early period, to make experiments on pendulums made of different metals, in order to counteract the effects of heat and cold. In the year 1736 Harrison was brought into notice by a pendulum clock which he had made in 1726, and which, for ten successive years, kept remarkably exact. This clock was tried in a voyage to Lisbon during August 1736, when it corrected an error in the ship's reckoning of 1° 30'. At the special request of the commissioners of longitude, who advanced him money, he continued his experiments on watches from 1737 till 1761, when he produced three watches, or time-keepers,—the third the most accurate, and about 4 inches in diameter. This watch, or chronometer, was tried in a voyage to Jamaica as to its practicability in determining the longitude. The trial was eminently successful; the difference of time as shown by the chronometer indicating Greenwich or rather Portsmouth local time, and the local time of the place, being 4 seconds of time, which is equivalent to 1 nautical mile in the parallel of Jamaica. On the arrival of the vessel at Portsmouth, it was found that the error of the chronometer was only 1 min. 53.5 sec., or 28.375 for the entire voyage, which, in the parallel of Portsmouth, would be equivalent to 18 nautical miles. Since this error was within the limit prescribed by the act, Harrison claimed the full reward of £20,000; but the commissioners, considering the matter in all its detail, came to the conclusion that the watch was not yet sufficiently tried. In order, however, to testify their appreciation of the invention, they gave Harrison a grant of £5000, and requested him to improve the watch still further against a second voyage. This voyage was undertaken, in 1764, to Barbadoes; and that no misunderstanding might ensue, Maskelyne and Green were also sent out to make the necessary astronomical observations at that place. The difference of longitude, as shown by the chronometer and that by astronomical observation, was 43 seconds of time, which is equivalent to 10' 45" of space, or longitude. In consequence of the success attending this and the former trial, the House of Commons ordered one-half of the reward promised by the act of 1714, or £10,000, to be paid to Mr Harrison, the inventor of the *longitude clock*; the other half to be paid him when watches, constructed on principles stated by him, should determine by trial the longitude of any place to within 30 nautical miles. Another condition annexed to the payment of the other £10,000 was, that the inventor should give on oath a full explanation of the principles on which the watch was constructed. This was done most willingly, and Harrison delivered over all his watches to government. The first watch made on Harrison's principles was that by Mr Kendall; it was found to exceed the regularity of the best of its models. This instrument was committed to the care of Mr Wales, in his voyage round the world with Captain Cooke, during the years 1772, 1773, &c., and such was its success, that in 1774 an appeal was made to the House of Commons to order the remaining sum to be paid to Mr Harrison, which was accordingly done. Harrison realized by his invention alone upwards of £24,000.

Several other parties received rewards for their improvements in chronometers, Arnold and Son received £3000, and Mudge £500.

Longitude. Since Harrison's time, remarkable improvements have been made in time-keepers, or *chronometers* as they are now termed; no one sustaining a good character that gains or loses more than a single second in one day.

But while watches were thus gradually being perfected, the tables of celestial motions were also attended to. Halley, on succeeding Flamsteed as astronomer-royal, continued improving what the latter had begun, so that for 1730, and consequently for the future, the *Caroline Tables* were presumed to give the true place of the moon, within the compass of 2' of her motion. But however perfect such tables may be made, they will be useless without a proper instrument with which to take angles accurately at sea. Dr Halley proposed to overcome this obstacle, by using on shipboard a telescope of 5 or 6 feet; but the error in such a case would nearly equal 2°, or under the equator the longitude would be in excess or defect about 40 leagues. But in 1761, Mr Hadley communicated to the Royal Society the nature of the *sextant* which he had then invented. The sextant is an instrument for taking angles at sea with surprising accuracy; its principle depends on the law of the reflection of light. This instrument was tried in several voyages with wonderful success; but its results were most accurate when used with Professor Mayer's *Tables of the Moon*, computed for the meridian of Paris. These tables first appeared in the *Memoirs of Göttingen* for 1742, and a manuscript copy was sent in 1755 by Mayer to the Board of Longitude, setting forth, at the same time, his claim for some one of the rewards which he might be thought to merit. These tables were placed in the hands of Dr Bradley, astronomer-royal, who compared several hundred computed longitudes of the moon with his own observed longitudes, and never found a greater difference than 1'.5. Dr Bradley showed the commissioners the value of these tables. Mayer died in 1762; but having in the interval greatly improved his tables, his widow sent them in 1763 to the Board of Longitude. These are the tables which, in consideration of their value in finding the longitude at sea, were, by act of parliament, honoured with a reward of L.5000, which was paid, in 1765, to Mayer's widow. Dr Maskelyne, astronomer-royal, was at the same time requested to improve and correct them as far as possible, so that they might be compiled, and form the basis of a *British Nautical Ephemeris or Almanac*; and to print the same, in order to make the lunar tables of general utility. The first of the series of the *Nautical Almanac and Astronomical Ephemeris* was published in 1766, under the superintendence of Dr Maskelyne. It was published yearly by the Commissioners of the Board of Longitude. The *Nautical Almanac* has been greatly improved, corrected, and extended, under the able superintendence of Mr Airy, the present astronomer-royal; it is now published four or five years previous to the observations being made at Greenwich Observatory; hence in long voyages the set of tables may be taken out.

In consideration of Mayer having availed himself of Euler's *lunar theory*, the latter received from government L.300.

The several methods for finding the longitude are the following:—

To find the Longitude by a Chronometer.—Suppose that a chronometer is warranted to measure equal portions of time uniformly, and always indicates Greenwich local time; it is evident that, were this instrument carried to any station on the surface of the earth where also the local time is known, the local times of Greenwich and that place can be compared with each other. If the chronometer be carried to any station on the meridian of Greenwich, the chronometer and local time of the place will always coincide; but if it be carried to any station W. or E. of the meridian of Greenwich, then the time as shown by the

Longitude. chronometer will be in excess in the former case, but in the latter in defect of the local time of the place; the difference of local times gives the longitude of the place from Greenwich. The time may be converted into distance, at the rate of 15" to 1 hour. Chronometers can never be made perfect; they require, therefore, to be daily compared with the heavenly bodies, in order to ascertain if their motion has been uniform.

Such is the method of finding the longitude by means of a chronometer; but to show the care and trouble involved in the delicate operation of finding the difference of local times between any two places, it will suffice to state briefly the attempt of Mr Airy, astronomer-royal, to determine the longitude of Valentia on the W. coast of Ireland. Mr Airy considered it necessary to take into account the facility of land conveyance by railways, and of sea conveyance by steamboats. With respect to the former, the route by Bristol and Cork had the preference; but he found those advantages best combined by adopting the route by Liverpool and Kingston. It was at first proposed that the chronometers should be transmitted from Greenwich to Valentia without interruption, save for the purpose of winding them up and comparing them with a clock at Kingston. But Mr Sheepshanks, who acted in concert with Mr Airy, thought that, for the sake of accuracy, the arc of parallel from Greenwich to Valentia should be divided into two parts—that from Greenwich to Kingston, and that from Kingston to Valentia—which was the plan adopted. Thirty chronometers were employed, to be compared with the transit clocks which were set up at each station. The following were the *courses* of these chronometers:—The chronometers left Greenwich for the first time on the morning of 27th June, and reached Kingston for the last time on the morning of 27th July, having made nine journeys from Greenwich to Kingston, and eight from the latter to the former place. The chronometers then left Kingston for Liverpool on the evening of 27th July, and were returned to the former place the last time on the morning of 4th Aug., having made four journeys each way. They then left Kingston for Valentia on the evening of 5th August, and returned to Kingston the last time on the morning of 14th September, having made ten journeys each way. After a short delay, and transmission to Liverpool, the chronometers left that place for Greenwich on the morning of 21st September, and arrived finally at the latter place on the evening of 28th Sept., having made four journeys from Liverpool to Greenwich, and three from Greenwich to Liverpool. It was by this transmission of chronometers from Greenwich to Valentia, that the comparison of the clocks at these two places was made. At each station, moreover, the transits of stars across the meridian were compared with the right ascensions of the *Nautical Almanac* list, using the mean places of the *Greenwich Catalogue* of 1439 stars. By this means, and with the requisite calculations, the inclination of the planes was obtained. The results on the whole are, in time,—

Longitude of Liverpool W. from Greenwich.....	12 ^m 0 ^s .05
Longitude of Kingston W. from Greenwich.....	24 ^m 31 ^s .20
Longitude of Valentia W. from Greenwich.....	41 ^m 23 ^s .23

The whole of the operations, including everything relating to the longitude of Liverpool, Kingston, and Valentia, occupied nearly from the end of June to the end of September 1844.

Mr Airy considered it proper, after all his labour with the transmission of chronometers, to compare the deduced results with that found by geodetic calculation. For this purpose, he made a survey-triangulation, which extended in an easterly and westerly direction from Greenwich to Valentia. From this survey the distance in yards was known between these two places, measuring along an arc of parallel. Knowing, therefore, this distance, as also the

Longitude. inclination of the two meridional planes, the whole parallel passing through Greenwich was computed.

The inferences which Mr Airy deduces from the chronometrical and geodetic results are:—That the verticals at Liverpool and Greenwich are less inclined to each other, or that the earth's surface in England is flatter than accords with geodetic calculation; that the inclination of the verticals at Liverpool and Kingston is, sensibly, precisely the same as that given by geodetic calculation; and that the inclination of the verticals at Kingston and Feagh Main is greater than that given by geodetic calculation, or that the earth's surface in Ireland is more curved than the elements of geodetic calculation imply: but that upon the whole arc the difference of the chronometrical and geodetic results is very small; and, lastly, in latitude $51^{\circ} 40'$ the complement of the logarithm of the number of feet in 1" for an arc perpendicular to the meridian is 7.9928932, or the length of 1" in an arc perpendicular to the meridian in latitude $51^{\circ} 40'$ is 101.6499 feet. (See *Transactions of the Royal Astronomical Society of London*, 1847.)

To find the Longitude by Lunar Eclipses.—Since an eclipse of the moon is visible to one-half of the earth at the same time, this would seem to be an excellent method of finding the longitude. The different steps of the process are,—to compute the time at which an eclipse is to happen at the place of observation, and to compare this time with an accurate chronometer showing Greenwich time; or in the absence of this, the Greenwich time of the happening of the phenomenon must be looked for in the *Nautical Almanac*; or it may be computed by the observer from the lunar tables. But this method of determining the longitude is rarely used, owing to the difficulty of ascertaining the exact time of contact of the penumbra of the earth's shadow with the moon's limb at the beginning or ending of the eclipse. Sometimes, indeed, two observers of an eclipse at the same place may differ more than 2 minutes in noting the time of contact; and hence the error from this cause alone would be about 4 minutes of time, which would be equivalent to nearly 1° of longitude. It was proposed in the *Philosophical Transactions* of 1786 to diminish this source of error, by observing the contact of the earth's shadow with some remarkable spot on the moon's face. But although this method were more accurate, the unfrequency of lunar eclipses at sea renders the method of little use.

To find the Longitude by the Eclipses of Jupiter's Satellites.—Ever since the discovery by Galileo of Jupiter's satellites the observation of their eclipses by their primary has been used as a method of finding the longitude. Tables of these eclipses were constructed by Galileo; and it was the disagreement of these tables with actual observation that led Roemer to the discovery of the gradual propagation of light. (See LIGHT.) The first astronomical solution of the great problem of the longitude really dates from the discovery of these *secondaries*, for the tables of their eclipses were framed on scientific principles. The three interior satellites of Jupiter pass through his shadow, and are eclipsed at every revolution; the fourth, or outer one, at times escapes eclipse, grazes the umbra, or is partially eclipsed. The computed times at which the eclipses are to happen at Greenwich Observatory are noted in the *Nautical Almanac*, published three or four years in advance; so that if these tables are in the hands of any one distant from Greenwich, he has but to observe the eclipse, and calculate the time at which it occurs, to find the difference of the local times between Greenwich and the place of observation, and thus ascertain the longitude. The times of immersion and emersion are noted with much greater accuracy than the contact of the moon's limb with the earth's shadow.

But before these eclipses can be observed with ac-

curacy, a telescope of considerable power must be used; Longitude. and as it is extremely difficult to direct a telescope properly on shipboard, the method is practically useless at sea. But again, particular care is required in observing; for two observers at the same place, with telescopes of different magnifying powers and apertures, seldom agree within a second or two of each other; hence the mean of the results of immersion and emersion should be taken. But another source of error is, that no two or more observers will agree as to the instant of the total immersion, or of the complete emersion of the satellite; hence the only case in which this method is practically useful in determining terrestrial longitudes is that in which the instant of immersion and emersion are observed with the same telescope, and by the same observer, since in this manner he will find the precise instant of the satellite's opposition to the sun.

To find the Longitude by Signals.—If the difference of longitude between two places be small, it may be easily found by means of the bursting of a rocket, the oxy-hydrogen lime-ball light, or the explosion of gunpowder fired from the one place at a preconcerted time, and observed at the other place; the local times of these places being accurately ascertained, the longitude is known. These artificial signals, when fired from an elevated spot of country, may be seen, when the atmosphere is in a proper state, at distances varying from 30 to above 100 miles. An observer, therefore, distant from the spot at which the rocket or other signal is exposed, has only to observe the time when he sees it, and afterwards compare this time with the time when the rocket was set up, the difference of times giving the longitude of the one place from the other; if at one of the places the Greenwich time corresponding to that of the event is known, the longitudes of the places from that meridian are also known. It is here supposed that the gradual propagation of light leads to no appreciable error in the small distance between the two places.

If the distance between the two places be considerable, and if a rocket sent up at the one place cannot be seen at the other place the longitude of which is required, then a series of signals must be made and noted by observers, placed at stations intermediate to the two extreme places.

Thus, let A and E be the two places, the longitude between which is required; B, C, and D, observers at intermediate stations; *w, x, y, z*, signal places, and let these places be arranged in the following manner:—

A *w* B *x* C *y* D *z* E.

Before the signals are sent up at the previously arranged hours from *w, x, y, z*, the local times of the places along the whole line AE are supposed to be accurately known. Let then a signal be sent up at *w*, and noted at A and B, the difference of times of observation, as noted by the chronometers at those two places, will give the longitude AB. Let, again, another signal be sent up at *x*, and the time of appearance noted at B and C, then the difference of times, as shown by the chronometers, gives the longitude between B and C; and therefore between A and C. Similar results will be found when signals are sent up from the stations *y* and *z*, to be observed at C and D, D and E; and in this manner, the whole longitude AE between the extreme stations can be found. The longitude found on this principle, and the mode of deducing the most advantageous results from a combination of all the observations, is fully stated by Sir John Herschel in the *Philosophical Transactions*, 1826, on the *Difference of Longitudes of Greenwich and Paris*.

Natural signals might be adopted in place of artificial ones, especially if they occur in sufficient number. Thus, Halley is said to have first suggested the idea of employing

Longitude. shooting stars, or meteoric stones, for determining the differences of longitude by simultaneous observation. Dr Maskelyne, in 1783, drew the attention of astronomers to these phenomena, and distinctly pointed out their application to this subject. The idea was revived in 1802 by Benzenberg; but so long as these shooting stars were regarded as casual and irregular phenomena, it was not to be expected that they could be of much service in geodetic measurements. Since, however, these meteors are known to be regular in their appearance, especially on the 9th and 10th of August, and on November 12th and 13th; and since they are visible over extensive regions of the earth's surface, they may be advantageously applied, by previous concert and agreement between distant observers to watch and note them. Mr Cooper has thus employed the meteors of the 10th and 12th of August 1847 to determine the difference of longitudes of Markree and Mount Eagle, in Ireland. Those of the same epoch have also been used in Germany for ascertaining the longitudes of several stations, and with very satisfactory results.

To determine the Longitude by Moon-culminating Stars.—This method consists in finding the increase of the moon's right ascension in the intervals between the passage of the moon over the meridian of Greenwich and over that place whose longitude is required. It is necessary to find the right ascension of the moon's bright limb, and of a star selected on, or as near as possible to, the moon's parallel of declination, and not differing much from her in right ascension at the two meridians; then, the moon's increase of right ascension being known, the difference of longitude is determined.

Let T , for example, be the time when the moon's enlightened limb transits the meridian of any place distant from Greenwich; t the time of passage of a star over the meridian of the same place; let also n be the error of the clock in the course of the day; then $24 + n$ will be the interval of time elapsing between two successive transits of the same star, and $24 + n : T - t = 360^\circ$: the difference of right ascension of the moon's bright limb and the star at the instant of the limb being on the meridian; and if to this the right ascension of the star be added, the right ascension, $= a'$, of the moon's bright limb when on the meridian is determined. Now the proper stars to be observed for this purpose, as well as the right ascension of the moon's bright limb when on the meridian of Greenwich, are given for every day of the year in the *Nautical Almanac*, from which the daily increment of right ascension may be determined. Let a be the right ascension of the moon's bright limb when on the meridian of Greenwich, e the increment of right ascension in the time between two successive transits over the same meridian; then, whilst the moon, by her relative motion, separates from the meridian of Greenwich by an angle of 360° , its real motion in right ascension is e ; and whilst it separates by an angle equal to the difference of longitude, the motion in right ascension is $a' - a$; and, therefore, supposing the change in right ascension uniform, the required longitude $= \frac{a' - a}{e} \cdot 360^\circ$. Where greater accu-

racy is required, the difference of longitude corresponding to the increase of right ascension $a' - a$, must be determined by interpolation. This method is considered one of the best which can be adopted for determining the longitude of distant places, when the observer, furnished with a transit instrument, can obtain a landing. (*Hymer's Astron.* 1840.)

To find the Longitude by the passages of the Moon over the Meridian.—If the sun, moon, and a star be supposed to be on the meridian of Greenwich at the present moment, then in the next instant the three bodies will be separated from each other,—the star will be found most advanced to the W., the moon least advanced from the meridian, while the sun will occupy an intermediate situation. The meridian itself also leaves these bodies, but will approach

them with different degrees of velocity, and reach each of Longitude. them after certain intervals of time. It will pass the star after the lapse of a sidereal day, or after having described 360° ; it will pass the sun at the end of a solar day, or after having described $360^\circ 59' 8''.3$; and it will pass the moon after a time $=$ the sum of 24 hours and the moon's *retardation* for that time, or after having described an angle $=$ the sum of 360° and the moon's right ascension in 24 hours. This always takes place in the interval between two successive transits of the moon over the same meridian. So also a spectator on a different meridian will notice similar effects, but less in degree, and less proportional to the distance of his from the first meridian. The sun's right ascension will be increased (or the separation of the sun from the star), but less than $59' 8''.3$; the moon's right ascension (or the separation of the moon from the star) will also be increased to the spectator, but less than its increase between two successive transits; consequently there will be an excess of increase of the moon's right ascension above that of the sun's, but less than the excess that takes place between two successive transits of the moon over the meridian of Greenwich. Wherefore, since the spectator at the second meridian may compute the respective increments of right ascension of moon and sun that take place between two successive passages of the moon over the meridian of Greenwich; then, since he is also able to compute, by actual observation, the right ascensions of sun and moon at the times of their passage over his own meridian, he has determined the longitude. The spectator may choose the sun and a star, the moon and a star, or the moon and sun; the two former are preferable. (*Woodhouse's Astron.*, 1821.)

To determine the Longitude by means of Eclipses of the Sun, or by Occultations of Stars by the Moon.—One of the most exact methods, and at the same time the simplest, for finding the longitude, is by means of solar eclipses and occultations. If the commencement and ending of an eclipse of the sun, or the immersion and emersion respectively of a star from the enlightened and dark limb of the moon or of a planet, be observed, it is only necessary to deduce the true time of conjunction for Greenwich and also for another place of observation; the difference of the times gives the difference of meridians, and therefore also of longitudes. Kepler employed this method, and it is one of the simplest. (*Kepler, Astron. pars opt.*) The only inconvenience of this method is the large amount of calculation required.

To find the Longitude by Lunar Distances; that is, by the distance of the Moon from a Star or the Sun.—This method supposes that the face of the heavens is a dial-plate, the stars marks apparently irregularly distributed upon it, and the moon the hand moveable among them and round the earth as a variable centre. Three things require particular notice about this clock;—1. The intervals of space separating the principal and secondary marks from one another and from the moving hand—the moon. 2. The exact amount of the eccentricity of the earth, the centre of motion of the hand. 3. The proper motion of both moon and earth at any part of their respective paths. When these data are properly known, the time as shown by this clock may be read. The time as pointed out on this dial-plate is generally read at Greenwich Observatory, and tabulated in the *Nautical Almanac*, four or five years beforehand, for every three hours. But this clock is supposed to be accurately seen by a spectator at the centre of the earth, and consequently, since observers are on the surface, the moving hand being rather near, and the marks immensely distant from the earth, it is evident that this moveable hand will be displaced, or undergo a *parallax* with respect to the stars, which must be allowed for, ere the true place is known which she occupies in space, as seen from the centre of the earth. A reduction must also be made to the

Longitude. centre of the earth. The necessary steps for computing the longitude by this method are,—(1.) Find by a sextant the distance between a star and one of the moon's limbs; or, between the limbs of the sun and moon; add or subtract, in the former case, the semi-diameter of the moon, and in the latter, the sum of the semi-diameters of sun and moon, which gives the distance of the moon's centre from the star, or that between the centres of sun and moon. (2.) When two observers are making the observations, one should take the above distance, while at the same instant the other takes the altitude above the horizon of the moon and star, or of the moon and sun. In the case of one observer, he must take the altitudes immediately before and after the distance has been found, and allow for the changes of altitude which may have taken place in the intervals between their observations and that of the distance. (3.) The true altitudes are derived from the apparent and observed, by correcting the latter for refraction and parallax; the *apparent* altitude being the observed altitude corrected for the dip of the horizon and instrumental errors. (4.) The observed is also an apparent distance, and must, like the altitude, be corrected for parallax and refraction in order to find the true distance. (5.) Since the true distance is found, the hour, minute, &c., of Greenwich time corresponding to it will also be found by the tables of the *Nautical Almanac*. (6.) The local time of the place of observation is now to be computed from the true and corrected altitude of a star or the sun, the sun's or star's N. polar distance, and the latitude. (7.) The difference between this local time and Greenwich time gives the longitude.

To find the Longitude by the Electric Telegraph.—This beautiful and ingenious application of electricity for recording astronomical observations is the latest method of finding the longitude, and was proposed by Mr Bond of the Cambridge Observatory, United States. Mr Airy, of the Greenwich Observatory, has also carried it into effect with great improvements. During the summer of 1847 experiments were made on the electric telegraph connecting New York, Philadelphia, and Washington, for the purpose of determining the differences of longitude between these three cities. A competent observer was stationed at each observatory. A continuous wire connected the three cities, so that telegraphic signals might be exchanged between any two of them at pleasure. In some of the first experiments, signals were exchanged between Philadelphia and Washington, but it was found impossible to transmit signals from Jersey City to Washington, the power of the battery being inadequate to that distance. This, however, was remedied on the 29th of July, when twenty clock signals were given at Jersey City, and recorded both at Philadelphia and Washington; twenty signals were given at Philadelphia and recorded at Jersey City and Washington; and twenty signals were given at Washington and recorded at Jersey City and Philadelphia. Thus the comparison of the three clocks was decisively made in a remarkably short period of time. The success of these experiments amply repaid the first unsuccessful efforts. The difference of longitude between Jersey City and Philadelphia is $40^m 3^s$; and between Jersey City and Washington, $12^m 3^s$; omitting in each case the small fractional part of a second, which was ultimately allowed for. The distance between New York and Washington is 225 miles, and the time required to make a communication pass betwixt these two places was a fraction of a second which cannot be measured.

Soon after a system of telegraphic wires was erected on the principal English lines of railway, Mr Airy had them put in communication with Greenwich Observatory, his object being to give *Greenwich time* on a given day to the United Kingdom. It was at first proposed that a ball should be dropped from the upper part of Greenwich Observatory, so as to touch a spring communicating with all the tele-

graphic wires in the kingdom, and then, by the striking of a bell, give instantaneously true Greenwich time to Liverpool, Manchester, and all the northern towns. But this method was found impracticable, owing to the non-completion of all the lines with Greenwich. On the 1st of December 1847, true Greenwich time was communicated directly from the observatory to the several stations of the London and North-Western and Midland lines in connection with it; but to all other stations of these lines special messengers were sent with chronometers indicating true Greenwich time. Hence, since Greenwich time is used over the whole of the United Kingdom, if the local time of any place be known, its longitude from Greenwich is also determined.

Since submarine cables connect Greenwich with Brussels and Paris, and these again with the principal cities of Europe, Mr Airy was very lately enabled to correct the latitudes and longitudes of their observatories. Hence, also, when the submarine cables which are to connect India, Australia, and America, with Greenwich, shall have been completed, the true longitudes of the principal cities of the world will easily be determined.

LONGOBARDI. See **LOMBARDS**.

LONGOBUCO, a town of Naples, province of Calabria-Citra, situate in a valley 21 miles N.E. of Cosenza. The inhabitants are chiefly employed in the neighbouring argentiferous lead mines, and in the burning of charcoal. Pop. 8000.

LONGOMONTANUS, CHRISTIAN, a Danish astronomer, the son of a poor ploughman, was born in 1562. His original surname, Severin, was changed into Longomontanus, an epithet derived from the Latinized name of his native village Langoberg. Compelled from a very early age to earn his bread by field labour, he received little or no school education. However, by the aid of the minister of the place, he instructed himself, and at the same time fostered so keen a desire for learning, that at the age of fifteen he stole away from his family, and entered the College of Wiborg. Here he remained for eleven years, and though forced at the same time to gain a scanty support by toil, progressed rapidly in his studies, especially in mathematics. He then removed to Copenhagen, and there becoming known, through his high attainments, to the professors of the university, he was recommended by them as assistant to Tycho Brahe. With this celebrated astronomer he continued for eight years engaged in astronomical calculations and observations, and living successively at the island of Høene and at the castle of Benach, near Prague. From this latter place, Longomontanus set out in 1601, and after travelling by a circuitous route, arrived at Wiborg in 1603. There he was immediately appointed superintendent of the gymnasium. In 1605 he became professor of mathematics in the university of Copenhagen. Longomontanus died in 1647.

His principal works are, *Astronomia Danica*, 1622, 4to; *Systematis Mathematici, Part I.*; *Cyclometria e Lunulis reciproce demonstrata*; *Geometriae Quasita XIII. de Cyclometria rationali et vera*; *Rotundi in Plano seu Circuli Absoluta Mensura*; and *Inventio Quadraturæ Circuli*. In this last treatise an attempt was made to square the circle, which was proved by Dr John Pell to be unsuccessful. Yet, at the end of an animated dispute with this mathematician, Longomontanus remained unconvinced of his error.

LONGTOWN, a market-town of England, Cumberlandshire, on the left bank of the Esk, 9 miles N. by W. of Carlisle, and 3 miles from the Scottish border. Its streets are regularly laid out and clean. The inhabitants are mostly employed in hand-loom weaving and agriculture. Weekly markets on Monday and Thursday; the former for butter and bacon, the latter for grain. Pop. (1851) 2142.

Loo-Choo
Islands.

LONGUS, a Greek sophist, the author of the pastoral romance entitled *Ποιμενικά τὰ κατὰ Δάφνην καὶ Χλόην*, and commonly called *The Loves of Daphnis and Chloe*, lived in the fourth or fifth century. Regarding his life nothing is known. His work is admired for its natural elegance and simplicity, but occasionally betrays a want of purity both in taste and in morals. It was first printed by Columbanus at Florence in 1598, 4to. The best editions are those of Boden, Leipzig, 1777, 8vo; Villosion, Paris, 1778; Schæfer's, Leipzig, 1803, 8vo; Passow, Leipzig, 1811, 12mo; and Seiler, Leipzig, 1843, 8vo. Courier's edition, published in 1810, contains a passage which he found in the manuscript in the Laurentian library at Florence, and which fills up a gap apparent in all the other manuscripts. Longus was translated into English by Thornley, London, 1657, 8vo; and by Le Grice, London, 1804, 12mo.

LONGWY, a fortified border town of France, department of Moselle, near the Chiers, a tributary of the Meuse, 33 miles N.N.W. of Mentz, and about a mile distant from the Belgian frontier. It is divided into an upper and lower town. The former is situate on an elevation once occupied by a strong castle, which was destroyed, and replaced in the time of Louis XIV. by a town fortified by Vauban. The latter, which contains most of the manufactories, lies underneath the southern escarpment of the upper town. The chief public buildings, including the town-hall, the principal churches, and an hospital, belong to the upper town; while the manufactures of calico, Delft ware, and porcelain, are carried on in the lower town. Longwy has sustained many sieges. In 1792 it was taken by the Prussians under the Duke of Brunswick, and again in 1815 by the allies under the Prince of Hesse Homburg, after a gallant resistance. Pop. 3374.

LONS-LE-SAULNIER, the capital of the department of Jura in France, and a town of considerable importance, is situate on the Solvan, not far from its source, in an agreeable valley surrounded by the mountains of the Jura, whose lower slopes are clad with vineyards. It is clean and well built, possesses tribunals of first instance and of commerce, a library, and a college; it has a handsome church and museum of antiquities, and is ornamented by beautiful fountains. At one end of the town is a brine spring or well, 60 feet deep, supplying the saltworks, *Salins* (whence the ancient name *Ledo Salinarius* and the modern *Saulnier*). These saltworks are situate at Montmorot, about a mile from the town, whither the brine is conducted by a wooden canal, with immense evaporating houses for strengthening the brine before it is boiled, in order to spare fuel. The tanworks of the place are important, and there is a tolerable trade in salt, iron, building timber, wine, cheese, &c. Pop. 9410.

LOO-CHOO ISLANDS, a group consisting of about 36 islands in the North Pacific Ocean, between Japan and Formosa. They lie between N. Lat. 24. and 28. 40. and E. Long. 127. and 129. They are small and insignificant, with the exception of Great Loo-Choo, which extends about 60 miles in an N.E. direction, and has an average breadth of about 10 or 12 miles. This island is entirely encircled by coral reefs, which, however, do not appear above water. Along its centre runs a chain of hills, covered for the most part by forests of pine, and broken at intervals by abrupt crags that bear seeming traces of volcanic action. Their slopes in many parts are covered with terraced gardens and fields of grain, and are watered by streams led in artificial channels. The valleys are well watered, fruitful, and covered with a luxuriant vegetation. The villages are almost completely hidden among groves of bananas, bamboos, banyans, and pines. Rows of trees overarch the roads, line the streets of the chief towns, and form a screen in front of the houses. There are large rich fields of rice, intermingled with crops of sugar-cane, wheat, millet, sweet potatoes,

plums, oranges, cotton, and tobacco. The principal surface-rock is argillaceous, and is intersected at intervals by peculiar ridges of limestone. The disintegration of the former rock forms the chief ingredient of the rich adhesive soil which is most prevalent in the island. Situate within the range of the trade-winds, Loo-Choo has in general a mild climate. The domestic animals are,—geese, ducks, fowls, pigs, goats, a small species of black ox, and a nimble and hardy breed of horses. Wild boars abound in the extensive forests. A striking trait in the zoology of the island is the scarcity of birds in the woods.

The dress, customs, but especially the language, of the Loo-Chooans, indicate a Japanese origin. Suspicious of strangers, they are, nevertheless, gentle and hospitable. They are diminutive in stature, and in complexion resemble the Chinese. They have dark eyes and black hair, plaited into a knot on the crown of the head; and the character of the hair-piu determines the sex as well as the rank of the weaver. The women wear single and the men double hair-pins. Among the higher classes, these articles are made of gold or silver; among the lower, of brass, lead, or pewter. The highest grade of society includes the spies and officers of the government, and also the mechanics and small merchants. Immediately below them are the literary class, who pass the most of their time in smoking tobacco and drinking tea, and are supported by the subordinate rank of field-labourers. The meanest order are the public slaves, possessing no personal freedom and no civil rights. Subjected from mere infancy to perpetual toil, closely watched by spies, and prevented from all intercourse with strangers, the lower classes are spiritless, uncomplaining drudges, subsisting upon two-tenths of the produce they reap from the soil. In the same slavish labour the women also are engaged. The Loo-Chooans of one village seldom intermarry with those of another. Their dead are treated with great respect; and their capacious tombs, built of white limestone, appear at a distance like cottages chequering the hill-sides. The huts are generally placed in the middle of well-cultivated gardens. Their floors, covered with thick mats, are used both for sitting and sleeping. A great part of the industrial population are engaged in weaving the grass-cloth that forms the ordinary garment, and in turning wooden implements and covering them with lacquer. There are also manufactured tobacco, sugar, and small quantities of salt. Saki, a strong intoxicating liquor, is distilled from rice. All the processes of agriculture, and especially that of irrigation, are carried on with great success. The entire trade of the island is with Japan, and consists chiefly of sugar, saki, and grass-cloth. Napakiang, situate in the S. part of the island, is the chief port. The government of Loo-Choo seems to consist of an oligarchy of *literati* subject to Japan. Learning is limited to a knowledge of the Chinese character and the Confucian classics, and the principal means of disseminating it is home education. A few regular schools, however, are scattered over the island, and at Napakiang there is an advanced seminary. The Loo-Chooans have no native literature. Their religion is a hybrid between Confucianism and Buddhism. Concerning the history of the island nothing certain is known, but tradition reports that it was once subject to three distinct sovereigns.

LOODIANA, in Hindustan, a town of Sirhind, is so called from having been founded by the Lodi tribe of Afghans. The population, consisting chiefly of Mohammedans, has been estimated at about 20,000 souls. Here Shah Zeman Dooranee took refuge after he had been deposed, deprived of sight, and exiled from Cabul; and his brother, Shah Shooja, also here found an asylum until his departure, in 1838, to attempt the recovery of the sovereignty of Afghanistan. The district, of which this town is the chief place, lapsed to the British on the failure of heirs to the late ruler in 1836. It has an area of 725 square

Loodiana.

Looe
||
Lord.

miles, and a population of about 120,000. The town of Loodiana is situate in Lat. 30. 55., Long. 75. 54.

LOOE, EAST and WEST, two villages of England, S.E. coast of Cornwall, on the Looe estuary, connected with each other by a stone bridge, 15 miles W. of Plymouth. They are of considerable antiquity, and at one time were of importance as seaports, having sent twenty ships to the siege of Calais in the time of Edward III. The east town was a borough, returning two members to parliament from the reign of Elizabeth, and the other returned the same number from the time of Edward VI., till both were disfranchised by the Reform Bill. The present villages are made up of irregular lanes, of antique houses, overlooked by beautifully-wooded hills, which almost surround them on every side. The inhabitants are principally engaged in pilchard fishing, and in the shipment of copper and granite brought by canal from Liskeard. Pop. (1851), East Looe, 970; West Looe, 746; total, 1716.

LOONGHEE, a town of the Burman empire, situate on the E. side of the Irrawaddy, Lat. 19. 39., Long. 94. 59.

LOPEZ DE VEGA. See VEGA.

LORARII, amongst the Romans, officers whose business it was, with whips and scourges, to compel the gladiators to engage. The *lorarii* also punished slaves who disobeyed their masters.

LORCA (the ancient *Eliocroca*), a town of Spain, province of Murcia, and about 40 miles S.W. of the town of that name. This town is situate on the southern skirt of the Sierra-del-Caño, on the summit of which is a fortress still in a state of defence. It is divided into an upper and lower town by the River Guadalentin, only since 1847 crossed by a bridge. Formerly communication was cut off during the annual floods. The upper and more ancient part of the town consists of wretched and narrow streets; the lower is more spacious and extensive. The principal buildings are,—the collegiate church of St Patrick, a beautiful structure of the sixteenth century; the former college of the Immaculate Conception, since 1837 incorporated with the university of Granada; the episcopal palace of the diocese of Cartagena; and the churches of Santiago and Santa Maria. On account of the long droughts, the scanty waters of the Guadalentin are collected above the town in two reservoirs for the purpose of irrigation. In the spring of 1802 one of them burst and caused great damage. The environs of the town are woody and picturesque, and there are several fine parks and promenades. The manufactures are chiefly soda, soap, saltpetre, linen, silk, oil, and paper. The trade is of no great importance, consisting in articles of local production—barley and wheat in good years, soda, and some other articles. There is an annual fair from the 8th to the 23d September, chiefly for the sale of cattle, and especially of mules, which are employed in the husbandry of the district. The Sierras contain minerals, which are worked to a considerable extent; some years ago great hopes were excited, and much capital embarked, in the lead mines, terminating in considerable losses. The town is remarkable in history as having been the key of Murcia during the Moorish wars; being situate on the frontiers of Granada, it was often taken and retaken. During the French occupation in 1810, the inhabitants suffered greatly from military violence, having taken up a position of decided hostility towards the invader. The painters Juan de Toledo, Pedro Camacho, and Baltasar Martinez were natives of Lorca. Pop. 40,469.

LORCHA, the name of a coasting vessel used in the Chinese seas. One of those vessels sailing under British colours was, in 1856, boarded by the Cantonese, had her flag pulled down, and her crew forcibly carried off. Governor Yeh refused either reparation or apology, and this led to the conflict between Britain and China during the same year.

LORD, a title of honour given to those who are noble

either by birth or by creation. The title is also by courtesy given to all the sons of dukes and marquises, and to the eldest sons of earls; and it is likewise a title of honour bestowed on those who are honourable by their employment, as Lord Advocate, Lord Chamberlain, Lord Chancellor, and the like. The word is Saxon, but abbreviated from two syllables into one. "The etymology of the word," says Coates, "is well worth observing; for it was composed of *hlaf*, a loaf of bread, and *ford*, to give or afford; so that *Hlaford*, now *Lord*, implies a giver of bread, because in those ages such great men kept extraordinary houses, and fed all the poor."

LORDS, HOUSE OF. See PARLIAMENT.

LORETO, a city in the province of Macerata-e-Camarino, in the Papal States, standing on a hill 3 miles from the Adriatic, on the E. coast of Italy. Though but a small city, consisting of little more than one long and narrow street, yet it has obtained a wide celebrity as a religious sanctuary. The Santa Casa, or Holy House, sacred to the Madonna, and said to be her birthplace, the scene of the Annunciation and Incarnation, as well as the place where the holy family found shelter after their return from Egypt, was, as the story goes, transported from Nazareth by the hands of angels to the coast of Dalmatia in 1291, and was afterwards, in 1294, conveyed in the night, in the same miraculous manner, to a laurel grove near Loreto. From this laurel grove, or from Lauretta, the person to whom it belonged, the place received its present name. To afford accommodation to the pilgrims which flocked thither, the foundations of the present town were soon laid. One side of the piazza, in which the sanctuary is situate, is occupied by the convent of the Jesuits, the other by the splendid palace of the governor, built after the design of Bramante. In the middle is the statue of Pope Sixtus V., who, in 1586, fortified the place against the attacks of the Turkish pirates, for whom the treasures of the sanctuary had considerable attractions. This piece of art is the work of Calcagni of Recanati. On the third side of the square stands the church called the Chiesa della Santa Casa. Over the grand entrance is a full-length bronze statue of the Virgin and Child, by Girolamo Lombardo. The chief external ornaments are three superb bronze doors, divided into compartments, with bas-reliefs illustrating events in the history of the Old and New Testaments. These exquisite performances are the work of the sons and pupils of the celebrated Girolamo Lombardo of Siena, and were finished during the pontificate of Paul V. The campanile, designed by Vauvitelli, exhibiting a combination of the four orders, is of great height, and is surmounted by an octagonal pyramid, with a bell weighing 22,000 pounds. The great attraction of the church, however, is the Santa Casa, a small brick building of the rudest kind, 13½ English feet high, 27½ in length, and 12½ in breadth. It has a door on the north side, and a window on the west. Over the fireplace is a statue of the Virgin, of Lebanon cedar, black with age, said to be sculptured by St Luke. The statue is resplendent with jewels, and the value of the relics and treasures must be very great. All sorts of offerings, from all classes of worshippers, are to be met with—from the richest jewels to a cannon-ball of the warlike Julius II., or a wedding-dress of the king of Saxony. The marble casing which incloses the Santa Casa is one of the most remarkable monuments of the finest age of art. The design was by Bramante, and the sculptures by Sansovino, Girolamo Lombardo, Bandinelli, Giovanni da Bologna, Guilielmo della Porta, Sangallo, &c. It has four fronts of white marble, and the sculptures are in relief. These wonderful works were for the most part begun, if not finished, by Sansovino. Vasari pronounces his representation of the Annunciation, on the western front, an *opera divina*. The next object of attraction is the bap-

Lords
||
Loreto.

Lorica
||
Lorraine.

tistery, a splendid work in bronze, ornamented with bas-reliefs relating to baptism. The chapels of the various naves are superbly ornamented with reliefs, arabesques, fresco paintings, and mosaics from the paintings of the great masters. Besides its church, Loreto contains little that is worthy of notice. It has a population of 9700.

LORICA, a cuirass, or coat of mail, worn by the Roman soldiers, was made of various materials. One formed by numerous folds of linen was used rather in hunting than in warfare. The ordinary kind consisted of a skin or a piece of strong linen, covered with small plates of iron which resembled, both in their shape and in their manner of overlapping each other, the scales of a serpent or a fish. Sometimes cuirasses or hauberks, composed entirely of iron rings linked together, were worn by the Roman *hastati*. A less flexible but more impervious defence was the cuirass made of hard leather or of metal, and consisting of two parts (the one covering the breast and abdomen, and the other the back), united by hinges and leathern thongs.

LORIENT, one of the five great naval ports of France, and the principal town in the arrondissement of the same name in the department of Morbihan, is situate on the northern shore of the Bay of Biscay, where the rivers Scarf and Blavet, after mingling their waters, fall into the Bay of St Louis. It is a large and flourishing town, strongly fortified, tolerably well built, but not very clean, standing in an angle between two creeks, one of which forms the naval the other the mercantile port. The port, which is large and commodious, is walled off from the town, thereby excluding all view of the water from the inhabitants. It is the seat of a maritime prefecture, of a civil tribunal, of a tribunal of commerce, of a college, and of a school of naval artillery. The dockyard is the first in France for the building and equipment of ships of war; there is accommodation on its slips for the simultaneous construction of thirty ships of war. It has an arsenal, a park of artillery, engineering works, masting-sheds and forges, &c. There is a good trade in sardines, marine stores, iron, wax, honey, &c. The town is quite modern. Founded by the French India Company in the reign of Louis XIV., in 1664, it was not till the time of the Duke of Orleans that the company took full advantage of the accommodation of Lorient. The greater portion of the town was then built, and the port fortified. In 1745 it contained thirty-five frigates, besides a very great number of ships, averaging from 900 to 1200 tons burden. In the comparatively short space of thirty years Lorient had risen to the first rank of towns. On the dissolution of the company in 1770, it was made one of the stations for the French navy. Its population and shipping declined during the unsettled period of the Revolution, but since the peace of 1815 it has been more than restored to its former activity. Pop. 25,700.

LORN, a division of Argyllshire. See ARGYLLSHIRE.

LORRAINE is the corrupted form of *Lotharingia*, *Lothair-regne*, *Lotharii-regnum*, or kingdom of Lothaire. The son and successor of Charlemagne, Louis the Pious, divided the empire between his three sons; Lothaire, Pepin, and Louis. Subsequent to this division, he had, by a second marriage, a son named Charles. Louis the Pious wished to make a new distribution of his dominions, which should include this Charles. The wish led to an insurrection on the part of the three elder brothers, and to the temporary deposition of Louis the Pious. The mother of Charles was desirous of securing the empire for her son, but failing in this, she united with Lothaire, to the exclusion of his younger brother, Louis. Pepin was at this time dead. The old and imbecile emperor being restored to the throne, agreed to make Lothaire and Charles his sole heirs. On the death of the emperor, however, Lothaire found himself opposed by his brothers Louis and Charles, and the result of the bloody battle at Fontenay, in which 100,000 lives

are said to have been sacrificed for three unworthy princes, Lorraine. compelled Lothaire to agree to the terms imposed on him by his brothers. According to these terms, Lothaire was to retain the imperial title, but he was to possess only Italy and a territory which reached from the Mediterranean to the Netherlands, and which was partially bounded by the Rhine, the Rhone, the Meuse, and the Scheldt. Louis received Germany, and Charles willingly accepted France for his portion. The treaty of Verdun, which established these terms, was concluded in 843. The territory out of Italy, which was assigned by that treaty to the Emperor Lothaire, is said to have taken from him the name of Lotharingia. This, however, is an error. The district above described was a portion of the empire, and was subsequently split into the kingdoms of Austrasia and Burgundy. Among the political arrangements which followed the confusion supervening on the demise of Lothaire, the most important was that subdivision of territory between his heirs, by which his son Lothaire II. was invested with sovereign power over the districts between the Meuse and the Rhine (excepting certain cities on the banks of the latter river), the Scheldt and the Meuse, and some contiguous "counties." This district was the true Lotharingia, of which King Lothaire, son of the Emperor Lothaire, was the first sovereign. A glance at the map will show that this territory was so situate that, if its monarch gave offence, it could be easily invaded on the sides of either Italy, Germany, or France. On the other hand, Lorraine could give its support to either of its neighbours against the others. One consequence of this position was that the country was for centuries a brand of discord between the German empire and the kingdom of France.

Early in the tenth century, on the death of Louis II., the last German emperor of the blood of Charlemagne, Lorraine was recovered by the French king, Charles the Simple. Under that monarch we meet with the first *Duc beneficaire* of Lorraine. This was no other than that Reynier (Reginald or Raguiner) whose system and policy have been so pleasantly transmitted to us in the exquisite satire, *Reineke Fuchs*. Reynier's son, Gislebert, succeeded to the ducal stewardship. Sanguinary contests ensued between Germany and France; and finally, a division of the prize being agreed upon, that portion known as Upper Lorraine became a fief of the empire in the year 960, to be governed by dukes receiving their nomination from the kaiser. This species of administration lasted eighty years, when the Emperor Henry III. founded a line of hereditary dukes in the person of Albert of Alsace. This line, which commenced in 1044, flourished during seven centuries, at the end of which time Lorraine was finally annexed to the French crown, and Francis, the twenty-sixth duke from the Alsatian (whose genealogy partial heralds have traced from Hector, and more modest builders of races from Dagobert) exchanged the duchy of Lorraine for that of Tuscany, took the hand of Maria Theresa, and gave to the imperial house of Austria the name of Hapsburg-Lorraine.

A more famous line of dukes never challenged admiration. Occasionally we find one weary of his glory. Thus, after Albert, Gerard, Thierry I., and Matthew I., had successively enjoyed their ducal state, we meet with the astute Simon II., who, after twenty-two years of renown and responsibility, laid down his ducal cap, and ended his days in a monastery. His coronet was joyously worn by his nephew Ferry, or Frederick I., whose successor, Thibaut the Handsome, wore it more joyously still, but less happily, ending a gay life by poison, mixed for him by the hand of a favourite and ungrateful mistress. His brother and successor, the terrible Matthew II., is remembered for the summary manner in which he suppressed all desire to commit acts of injustice on the part of local governors by skinning one offender alive. Ferry II., in 1298, received

Lorraine. an accession of sovereign power in the imperial sanction to coin his own money. The second Thibaut reduced the authority of the aspiring Lorraine nobles as vigorously as Richelieu subsequently crushed that of the proud aristocracy of France. The third Ferry, surnamed the Wrestler, gave asylum in his duchy to the fugitive Templars, flying from the vengeance of other sovereigns. He is otherwise remembered as being the first of the Lorraine dukes who was a decided partizan of France. It was the ambition of all these dukes to obtain the title of king. Raoul, who followed Ferry the Wrestler, acquired the lordship of Guise, in Picardy, by his marriage with Mary of Blois; but this alliance with France was founded more on policy than affection. This "paragon of Lorraine dukes" was not unknown to our forefathers, for he was among the bravest of our foes counted among the dead on the well-stricken field of Cressy. Still better known to the English was his successor John, godson of John, King of France. John left his dukedom a prey to the luxurious nobles and to the peasantry, who massacred those nobles because of their licentious cruelty, and Duke John joined his fortunes with those of his royal godfather. Like him, the duke became our prisoner at Poitiers, hunted in our English woods, sojourned in our English castles, was now at large, anon under strict restraint, and was not released, even by the peace of Bretigny, under a less modest ransom than 30,000 livres.

Then ensued the period of disputed successions, the history of a portion of which is familiar to English readers who have perused the *Anne of Geierstein* of Sir Walter Scott. Charles, the son of our prisoner John, died without male heirs. His daughter, Isabella, was married to René d'Anjou, "Duke of Bar, King of Naples, Sicily, and Jerusalem," by whom the ducal coronet of Lorraine was claimed. René is famous for his lack of good fortune, his empty titles, and his love of poetry and minstrelsy. He was unable either to sustain the claim of his wife to the sovereignty of Lorraine, or to help his daughter, Margaret of Anjou, Queen of England, in her attempt to recover the crown of her husband, Henry VI. René and Isabella left the disputed coronet of Lorraine to be worn by their son John II., who was wiser than his father, and still more unfortunate. John's son, Duke Nicholas, was an exquisite dancer, but a very indifferent duke. His death left the seat of authority to be occupied by René II., but it was claimed by Charles, Duke of Burgundy, for the Count of Vermandois. The contest which arose is one of the principal features in Scott's romance, already named, and it ended unsuccessfully for the Burgundian by his defeat at Nancy, and his death in the marsh near the city. When his body was discovered there, the gentle René took the frozen hand, and exclaimed, "God have your soul, cousin, although you have caused me many a pain and sorrow!" René II. refused to confiscate the property of any of the adherents of Charles in Lorraine; and of all the rich spoil of the Burgundian camp, he retained only a crystal vase, out of which he drank, after the funeral of Charles, "to the oblivion of vengeance." When René died, in 1508, his wife Philippa took the veil in the convent at Pont à Mougeon. At the solemn ceremony, her youngest son, twelve years of age, placed in her hand the symbolic wax-light, and burst into tears as he turned from his mother, who for the next fifty years humbly signed herself "Sister Philippa, poor earth-worm." Of the good duke, René II., it is unnecessary to say more here than that from him sprang another line of dukes, of which we shall briefly speak at the close of this article, namely, the dukes of Guise.

Duke Antony, the eldest son of René II., has received the equivocal praise of Brantome, for many fine qualities and reputable virtues. He was French by education and inclination. His ducal coronet passed to the brows of three successive dukes, Francis, Charles, and Henry, before

a lineal succession was interrupted by the lack of male heirs at the decease of the last-named ducal sovereign. Henry was succeeded in 1614 by his nephew and son-in-law, the great Duke Charles, the most famous and most unfortunate of his house. He was renowned for his gallantry in the field and in lady's bower, and he prided himself on this double reputation. In the Thirty Years' War, he took the side of Germany against France, a partnership which for a time cost him his dukedom. His reconciliation with France did not induce him to consider the designs of the government of that country with less dread or suspicion. He evinced his antagonism by entering the Spanish service, and in that service he carried on war against the French crown, after the peace of Westphalia in 1648 had caused a cessation of hostilities between France and her other adversaries. But Charles found his worst foes amongst his latest friends, and his freedom of speech was exercised at the cost of his personal liberty. For some audacious criticism, the Spaniards put him under arrest in Brussels, transferred him to close captivity in Antwerp and Toledo, but released him in 1659, when Louis XIV. concluded the peace of the Pyrenees. The French monarch procured the enlargement of the duke on terms which made of the latter a very obsequious servant. His obsequiousness, however, went farther than the stipulations required of him; and when his nephew and heir, Charles Leopold, declined to enter into a marriage proposed to him by the duke, the latter forwarded a despatch to Louis XIV., which the French monarch received as he was enjoying the gay delights of the fair at St Germain, in 1661. When Louis had read the missive, he joyously remarked that he had obtained a more precious prize than could be found in the fair. The despatch from Lorraine contained an offer to make over the duchy to France after the death of Charles, on condition that the princes of the House of Lorraine should be reckoned among the princes of the blood-royal of France. When Charles Leopold heard of the offer, he fled to the emperor for protection. His uncle became the slave of Louis, and when Charles attempted to free himself from the galling yoke in 1670, he was driven out of his duchy by French troops. He died a soldier in the imperial service in 1675. There were difficulties in the way of the annexation of Lorraine to France which neither Louis nor the able Colbert could surmount. It is a singular circumstance, too, that during the early period of the sway of Duke Charles he was a proud assertor of his independence of France. He repaired to Versailles, indeed, to do homage for the dukedom of Bar, which was on French territory, but when the ceremony was concluded, he remarked that he hoped no one would construe the act as an acknowledgment of vassalage. The chancellor of King Louis expressed, in his turn, a hope that no chicanery was intended; at which the haughty duke looked at the legal gentleman, and asked if, by chance, he mistook him for a lawyer!

Charles Leopold only nominally reigned from 1675 to 1690. He might have returned to Lorraine, but he refused to accept the terms allowed him by the peace of Nimeguen. He made his name famous by his deeds in the wars of that period; and the recovery of the dukedom which was denied to him, was realized in the person of his son, Leopold Joseph, by the terms of the peace of Ryswick, in 1697, after Lorraine had been more than a quarter of a century in the possession of the French. The experience of his predecessors rendered Leopold Joseph wise. He loved peace rather than war; was respected equally by Germany and France, and while he cultivated the friendship of the former, he cemented his alliance with the latter by marrying Elizabeth Charlotte, daughter of Philip, Duke of Orleans. He died in 1729.

It seems paradoxical to assert that the glory of this ambitious house was consummated by the downfall of the

Lorraine. duchy. Such, however, is the remarkable fact. The son of Leopold Joseph was Francis Stephen, the last duke. He was popular, gentle, very much of a German by education, a moderate traveller, and was the lion of the London season, at the gay parties of 1731. Of the wars and political struggles of this period we cannot speak farther than as they influenced Lorraine. The possession of the duchy became necessary for the security of the French frontier. Cardinal Fleury finally effected the desired end. Francis married Maria Theresa, exchanged Lorraine for Tuscany, and, with his bride, ascended the imperial throne of Germany. The great hope of the House of Lorraine was thus accomplished. Maria Theresa and Francis could alike trace their descent from Gerard of Alsace, the nephew of the first duke of the hereditary line; and on grasping the sceptre of the kaisers they might have quoted, as fulfilled, the device of their race, *Spes adhuc restat avorum*. They were, as before noticed, the first of the line of Hapsburg-Lorraine.

The old duchy did not immediately revert to the French crown. Among the unseptrated monarchs of the time there was Stanislaus Leczinsky, who had been carried to the throne of Poland by Charles XII., and who was driven from it by Charles's enemies. Louis XV. married the daughter of Stanislaus, and gave the duchy, with all its privileges, to her father, in life-interest. The new Duke of Lorraine passed the most pleasant of lives under the protectorate of the worst of kings. He kept a brilliant court; governed with remarkable wisdom; was alternately religious and licentious; made of Nancy a city of parks and palaces; drank joyously the Tokay wine sent to him by Francis; cooked little dishes of his own invention, for which he is still gratefully remembered; dabbled in literature; wrote maxims for daily conduct, which embrace the wide distances between duty towards God and watchfulness against damp shoes; and, after a reign or residence of twenty-eight years, from 1738 to 1766, was burned to death by the ignition of his dressing-gown as he was stooping to light his pipe at his own fire.

After his decease Lorraine became a province of France; but the annexation was not carried into effect without various riots, in which the Lorraine women were especially conspicuous. As a province, it disappeared in the French Revolution, when provincial governments, with all their heavy oppressions, ceased. The ancient province was broken up into departments, and that part of the old kingdom of Lothaire is now divided into the departments of the Meurthe, the Meuse, and the Moselle.

The story of Lorraine would be very imperfect without some notice of the branch of Guise. Towards the end of the fifteenth century, René II. sent his fifth and youthful son Claude into France, to push his fortune. The boy grew up to manhood; served Francis I. with his sword; carried the double cross of Lorraine triumphantly over many a field, and acquired such power, that although Francis had made him Duke of Guise, the king warned his successor against the ambition of such men as the duke and his brother, the famous Cardinal John. It was the daughter of this duke, Mary, who married James V. of Scotland, and became the mother of Mary Stuart.

If these two Guises were the terror of all Protestants, still more so were Francis, the second duke, and his able but unscrupulous brother, Cardinal Charles. Side by side they governed France; revived her glory; impoverished the people, and enriched themselves. They overcame all political opponents; lived with a splendour which was unknown at court, and sealed their reputation—the first, by capturing Calais from the English; the second, by his sanguinary persecution of the Reformers. The reputation of the duke during the reigns of Henry II. and Francis II. was only equalled by that of his brother; and the kingdom was

never so much at the mercy of individuals as when it was brilliantly misruled by Duke Francis of Guise and Cardinal Charles of Lorraine. The duke was shot by Poltrot at the siege of Orleans; the cardinal survived to the reign of Henry III. Meanwhile, there succeeded to the dukedom Henry of the Star (Le Balafre), who was perhaps the most redoubtable antagonist that the Reformers ever had, as he was the most formidable subject ever possessed by helpless sovereign. To him and to Cardinal Charles may be traced the authorship of the plan carried out in that never-to-be-forgotten day of massacre—the day of St Bartholomew. When Charles IX. had passed away, the great struggle for power commenced between the new king, Henry III., and the Guises. It was a struggle for very existence, and in it the Guisards had the sympathy of the people, always excepting the Huguenots. The history of the horrors of the struggle comprises the darkest pages in the history of France. It was not closed when Henry III. got his namesake of Guise into his power at Blois in 1588, and there had him cowardly assassinated in the very bed-chamber of the king. The bloody struggle was only brought to an end when the sister of the murdered duke, Ann of Montpensier, put a knife into the hand of the Dominican, Clement, and he, inspired by her beauty and her promises, went and plunged the weapon into the bosom of the last of the Valois kings of France.

From this time the fortunes of Guise suffered retrogression. The fourth duke, Charles, escaped from his captivity at Tours, and joined the league against that over-landed monarch, "Henri Quatre." The triumph of this Bourbon king reduced the duke to comparative retirement. Cardinal Richelieu drove him into exile in the reign of Louis XIII., and this worthless duke was succeeded by his son, the more worthless Henry, who surrendered the dignity of a cardinal to assume the honours and responsibility of a dukedom. It was this libertine who, in 1647, headed the expedition by which, for a time, he succeeded Masaniello on the throne of Naples. After a life of great vicissitudes, he died, in 1664, a sort of "gold-stick-in-waiting" at the French court. Being childless, he was succeeded by his nephew, Louis Joseph, a youth who died of smallpox in 1671, and who bequeathed the once proud title of Guise to his infant son, Francis Joseph, who, in his turn, died of the same disease, the seventh and last of the Dukes of Guise, in the year 1675.

With the prestige of this house its pretensions did not expire. The French memoirs continually reveal to us the petty court quarrels and the silly struggles for precedence at state balls, carried on at court by ladies and gentlemen who could trace their descent from some younger branch (and there were many of them) of the House of Lorraine. The last of the race connected with the line of Guise was that Prince of Lambesc, colonel of cavalry, who, in one of the street riots in Paris, which, in 1789, were preludes to the Revolution, struck a rioter with the flat of his sabre, and for this assault upon the people was driven out of France, three centuries after his great ancestor, Claude, had entered it from Lorraine. The last of the Guises found a refuge at Vienna, where the heir of the elder branch of Lorraine held the imperial sceptre. The present Emperor of Austria is the representative of this ancient race; and he, as if unwilling to give up all connection with the old ducal province which has been so long annexed to France, still reigns supreme over a few square yards in Nancy, the old capital of the province. Those few yards are comprised within the walls of the church wherein are ranged the cenotaphs of all the dukes of Lorraine, and near which lies the body of one of whom Nancy is as proud as of her dukes—Callot, the great French engraver. The ecclesiastical staff of this edifice is in the pay of the Emperor of Austria, as representative of the ancient ducal family. The

Lossini
||
Lot.

edifice is said to be Austrian property; and while no repairs are made therein but at Austrian cost, so no appointments are concluded but under Austrian approval. Such is the last shadow of the symbol of authority over the once powerful dukedom of Lorraine. Of the race which once held sway therein, the younger branch, that of Guise, has become extinct; but the heir of the elder line occupies an imperial throne at Vienna, where he upholds a policy that would have been despised by Lothaire. (J. D-R-N.)

LOSSINI. See OSERO.

LOSTWITHIEL, a market-town of England, county of Cornwall, on the River Fowey, 5 miles S.S.E. from Bodmin. Its streets are narrow and roughly paved; and its houses are generally built of stone, and roofed with slate. The principal building is the parish church, a structure of the fourteenth century, surmounted by a spire, and containing a curiously ornamented old font. During the civil war, having been used as a barrack by the parliamentary troops, it was injured by an explosion of gunpowder. Near the church is the site of the ancient palace of the earls of Cornwall, now occupied by the stannary prison. There are also three dissenting chapels. Many of the population are employed in tanning, lime-burning, and the woollen manufacture. A considerable trade is carried on in lime, coals, iron, and timber. About a mile from the town are the fine ruins of Restormel Castle, another palace of the earls of Cornwall. Lostwithiel once returned two members to Parliament, but was disfranchised by the Reform Act. Pop. of parish (1851) 1053.

LOT, a department of France, formed from Quercy, part of the old province of Guyenne, is bounded on the N. by the department of Corrèze, on the E. by those of Cantal and Aveyron, on the S. by that of Tarn-et-Garonne, and on the W. by those of Lot-et-Garonne and Dordogne. It is situate between N. Lat. 44. 13. and 45. 5., and E. Long. 1. and 2. 10. It is 65 miles long by 35 broad, and has an area of 2168 square miles. The department is drained by two navigable rivers; the Lot in the S., from which the department takes its name, and the Dordogne in the N. The watershed of these two rivers is formed by a branch of the mountains of Auvergne. The Lot flows into the Garonne, and receives the Selle on its right bank near St Cirq. The Dordogne receives the Cère on its left. The principal minerals are coal and iron. The mountainous districts yield marble, granite, limestone, alabaster, millstones, and lithographic stones, and the valleys fuller's earth. The chief places of mineral wealth are—Miers, La Garde, and Gramat. Industrial manufactures have made little progress. There are some iron-works, potteries, and tile-kilns, and manufactories of coarse woollen stuffs, brandy, and paper. There is a small trade in those articles, besides wine, corn (which is pretty abundant), hides, salt, and groceries. The department is almost entirely agricultural. Wheat, maize, barley, and oats, are raised in the valleys and plains; and in the stronger soils, hemp and tobacco. The best wines are those of Cahors and Grand-Constant. The white mulberry is grown for production of silk, and truffles and plums are plentiful. Horses, mules, asses, cows, sheep, swine, and goats are numerous and of tolerable quality. The rivers abound in fish, of which the most noted are the eel and the carp. The department of Lot has three tribunals of first instance under the court of appeal of Agen, a tribunal of commerce at Cahors, a lyceum, two colleges, and a normal school.

The principal town of the department is Cahors, with a pop. of 13,350. Lot has three arrondissements, subdivided as follows:—

	Cantons.	Communes.	Pop. in 1851.
Cahors	12	127	118,515
Figeac	8	112	94,345
Gourdon	9	73	83,364
Total	29	312	296,224

Lot-et-Garonne
||
Lotteries.

LOT-ET-GARONNE, a department of France, formed chiefly of the old province of Guyenne, besides small portions of Condomois and of Lomagne, is bounded on the N. by the departments of Gironde and Dordogne, on the E. by those of Lot and Tarn-et-Garonne, on the S. by that of Gers, and on the W. by those of Landes and Gironde; between N. Lat. 44. and 44. 45., and W. Long. 0. 10. and E. Long. 1. 3. It is 63 miles long and 55 broad, and contains an area of 2067 square miles. It receives its name from the rivers Lot and Garonne, which traverse it in a westerly direction, and unite near the town of Aiguillon. The Garonne receives as tributaries the Baise and the Dropt; the former joining it opposite Aiguillon, the latter below La Réole. Another principal river is the Gers. Those rivers are, for the most part, navigable, or are rendered so by means of canals. Steamers ply between Bordeaux and Agen, and a railway has been projected from Bordeaux to Certe. The chief mineral productions are iron, gypsum, building-stone, and marl. The department possesses, as industrial establishments, a manufactory of tobacco at Tonneins, and one of beautiful sail-cloth at Agen. The remaining articles of manufacture are flour, linen, cotton, pottery, iron, glass, lime, paper, ropes, and leather. There is a considerable trade in those articles, as well as in agricultural produce, which is rich and abundant. The valleys of the Lot and Garonne are remarkably fertile and beautiful. The low grounds yield wheat, maize, rye, hemp, and tobacco; the upper slopes are covered with vines, figs, and plums. The N. of the department is rather barren. The climate is very healthy. A considerable number of horses, mules, asses, cattle, sheep, pigs, and goats are reared. Geese and game are also abundant. Lot and Garonne forms the diocese of the Archbishop of Agen, and has five consistorial churches of the Calvinistic persuasion. It has a court of appeal at Agen, four tribunals of first instance, three tribunals of commerce, and five colleges.

The principal town is Agen, with a pop. of 14,987; and the department is divided into four arrondissements, subdivided as follows:—

	Cantons.	Communes.	Pop. in 1851.
Agen	9	72	84,092
Marmande	9	96	101,044
Nérac	7	62	60,818
Villeneuve-d'Agen	10	82	95,391
Total	35	312	341,345

LOTHIAN, a name given to three counties of Scotland, —Haddingtonshire, Edinburghshire, and Linlithgowshire; otherwise called *East, Mid, and West Lothians*. (See the articles on these different shires.)

LOTTERIES, in their highest application, are institutions for raising the revenue of a country by granting to those who voluntarily contribute the chance of obtaining a reversion of part of the money collected. This reversion is determined by lot. The practice may be traced back to the Romans, who were accustomed, at least in the days of the empire, to enliven their festivals with the distribution of tickets uniform in appearance, but entitling the holders to receive articles of various value. Instead of granting largesses to the leaders of the Plebs, the Emperor Augustus frequently distributed his gifts on the same principle; and Heliogabalus has the merit of devising in sport a plan, frequently resorted to in fraud to avoid the penalties against lotteries in England, of making prizes really worthless take the place of blanks. In the middle ages the same practice prevailed at the banquets of feudal princes, who distributed their presents economically, and without the fear of jealousy, by granting lottery tickets indiscriminately to their friends. The practice soon descended to the merchants; and in Italy, in the sixteenth century, this became a favourite mode of disposing of their wares. In 1580 the "Lotto" of Florence was established for the necessities of

Lotti.

the state, and the example was quickly followed throughout Europe. The first lotteries with numbered tickets were instituted at Genoa. Mercantile lotteries were established in France under Francis I. in 1539, and a tax levied on each ticket; but these were supplanted in 1660 by lotteries of money, under the direct control of the king. The first lottery established in England was drawn in 1569. It consisted of 40,000 lots, which were sold at 10s. each. The prizes were pieces of plate; and the profits were devoted to the repair of certain harbours in the kingdom. The printed plan of this scheme is still in possession of the Antiquarian Society of London. In 1612 a lottery was granted in behalf of the Virginia Company; and in 1680 the same privilege was accorded to a contractor who undertook to supply London with water. From this time forward the spirit of gambling increased so rapidly, and grew so strong, that in the reign of Queen Anne, private lotteries had to be suppressed as public nuisances. The first parliamentary lottery was instituted in 1709; and from this period till 1824, the passing of a lottery bill was in the programme of every session. Up till about the close of the eighteenth century, the prizes were generally paid in the form of terminable, and sometimes of perpetual, annuities. Loans were also raised by granting a bonus of lottery tickets to all who subscribed a certain amount. This gambling in annuities, however, despite the restrictions of an act passed in 1793, soon led to an appalling amount of vice and misery; and in 1808 a committee of the House of Commons urged the suppression of this ruinous mode of filling the national exchequer. In October 1826 the last public lottery was drawn in Britain. In France state lotteries have been abolished, but they still exist in most of the continental states; and although demonstrably a source of loss to those who embark in them, they are upheld as a very ready mode of procuring money from the poor, the miserly, and the adventurous. The Hamburg lottery affords the most favourable representation of the system, as in it all the money raised by the sale of tickets is redistributed in the drawing of the lots, with the exception of 10 per cent. deducted in expenses and otherwise. In the United States lotteries were established by congress in 1776, but, with the exception of the southern states, heavy penalties are now imposed on persons attempting to establish them. Private lotteries are now illegal at common law in Great Britain and Ireland; and penalties are also incurred by the advertisers of foreign lotteries. Some years ago, it became common in Scotland to dispose of merchandise by means of lotteries; but this is specially condemned in the statute 42d Geo. III., c. 119. An evasion of the law has been attempted by affixing a prize to every ticket, so as to make the transaction resemble a legal sale; but this has been punished as a fraud, even where it could be proved that the prize equalled in value the price of the ticket. This decision rested upon the plea that in such a transaction there was no definite sale of a specific article.

In 1844 art-unions began to be established in Britain; and as the principle on which they are founded involves that of the lottery, their operations, which are in reality illegal, were immediately suspended by order of government. In the following year, however, an act was passed to indemnify those who had embarked in them for the losses which they had incurred by the arrest of their proceedings; and since that time, they have been tolerated under the eye of the law without any express statute being framed for their exemption.

LOTTI, ANTONIO, one of the great founders of the Venetian school of musical composition, was born at Venice about 1665, and died there in 1740. He studied music under Giovanni Legrenzi, and in 1693 became first organist of St Mark's, a position which he held till he was appointed chapel-master of that cathedral in 1736. In 1718 he was called to Dresden, in order to compose an opera for the

Elector of Saxony. He returned to Venice the same year, and then devoted himself to the study of music for the church. According to his continental critics, the style of his music is clear and expressive, and he possessed peculiar skill in writing parts for voices smoothly and melodiously—a rare and difficult branch of musical composition. In his madrigals and church music, he was considered superior to all other composers of his time. Most of his church music was deposited in the library of St Mark, and little of it published. He composed nineteen operas for the theatre. In 1705 he published at Venice a collection of his vocal duets and trios, and madrigals for four and five voices. One of these madrigals—“*In una siepe ombrosa*”—Bononcini (Handel's opponent in London) had the folly and impudence to publish as his own. This imposture was detected and exposed in 1732 and Bononcini having thus lost all credit, besides having become intolerably insolent and overbearing, quitted England for the continent in the following year. Latrobe, in the second volume of his *Selections*, gives a “*Qui Tollis*,” and, in the third volume, a “*Gloria in excelsis*,” by Lotti.

(G. F. G.)

LOTUS, a very famous plant amongst the ancients, but the name is applied to several different species. Fée signalizes eleven. The most celebrated is that from which the *Lotophagi* (or lotus-eaters) were designated. It grew in the Syrtic region of Africa, and is described by Polybius as a thorny shrub, with berries about the size of an olive, which were at first white, but afterwards acquired a red tinge. The taste of these resembled that of dates, and was supposed to have the property, when eaten, of causing strangers to forget their native country. Hence the proverb of “tasting the lotus,” as applied to those who travel far and neglect their own land. Modern travellers and botanists identify the plant now referred to as the *Zizyphus lotus*, found in Tunis and other parts of Africa. Park describes the berry as very sweet and affording a liquor, as was the case with the ancient lotus. When the fruit was ground into meal, baked into cakes, and dried in the sun, he found it to be delicious to the taste. It is the opinion of Munby, however, that the true lotus tree of the ancients is the *Nitria tridentata*, found in the desert of Soussa, near Tunis, producing a succulent fruit having stimulating qualities.

The lotus of the Egyptians is the *Nelumbium speciosum* of botanists (or sacred water-bean), supposed to have been the Pythagorean bean, from which he charged his followers to abstain. The blue species, often found sculptured on the walls of Egyptian temples, is, in all probability, the *Nymphaea caerulea*. Both the seed and the root of the former were used for food by the inhabitants. The plant appears frequently in the hieroglyphic representations of the rites of Isis and Osiris, to whom it was sacred, and was regarded as an emblem of the creation of the world from water. It was considered symbolical of the Nile, as the Indian lotus was of the Ganges.

LOUDON, JOHN CLAUDIUS, a famous writer on horticulture, was the son of a farmer in the neighbourhood of Edinburgh, and was born at Cambuslang, in Lanarkshire, in 1783. After attending a public school in Edinburgh, he was apprenticed, at the age of fourteen, to a nurseryman and landscape gardener in that city. Meantime he had become intimate with the theory of horticulture, as well by diligent private study, as by attending the classes of botany, chemistry, and agriculture, in the university. In 1803 he repaired to London, and through the high testimonials which he bore, soon obtained abundance of employment. Bent upon improving the inferior system of agriculture in England, Loudon in 1806 rented, conjointly with his father, a farm in Middlesex, and in the ensuing year published a pamphlet, entitled *An Immediate and Effectual Mode of Raising the Rental of the Landed Property in England*. The success attending his new vocation induced him to

Lotus
||
Loudon.

Loudun
||
Loughrea.

take a lease of the larger farm of Tew Park, in Oxfordshire. There he also established an agricultural college. After amassing by his enterprise a fortune of L.15,000, he set out, in 1813, on a tour, and having travelled in Sweden, Russia, Poland, and Austria, returned to England in 1814. The knowledge of foreign horticulture he thus obtained was still further enlarged by a visit to France and Italy in 1819, and formed an important part of his *Encyclopædia of Gardening*, published in 1822, with numerous woodcuts. A second edition of this great work appeared in 1824. Less successful, his elaborate treatise *Arboretum et Fruticetum Britannicum*, 1838, was sold slowly, and involved its author in a debt of L.10,000 to the printer, the stationer, and the wood-engraver. While toiling assiduously at this work, Loudon was also editing four monthly periodicals—an amount of activity extraordinary in a man whose right arm had been amputated in consequence of disease, and whose constitution had been seriously impaired by rheumatic fever. Enfeebled still more by this labour and its attendant anxiety, he yet continued his studies as unweariedly as ever, and immediately before his death in 1843, was engaged in a work entitled *Self-Instruction for Young Gardeners*. In addition to the works already mentioned, Loudon wrote—*Observations on the Formation and Management of Useful and Ornamental Plantations*, 8vo, Edinburgh, 1804; *A Short Treatise on some Improvements lately made on Hot-houses*, 8vo, Edinburgh, 1805; *A Treatise on Forming, Managing, and Improving Country Residences, and on the Choice of Situations*, 2 vols. 4to, London, 1806; *Encyclopædia of Trees and Shrubs*; *Encyclopædia of Agriculture*, 1825; and *Encyclopædia of Cottage, Farm, and Villa Architecture*, 1832. He also edited *Encyclopædia of Plants*, 1829.

LOUDUN, a town of France, capital of a cognominal arrondissement in the department of Vienne, situate on an elevation between the Dive, Creuse, and Martiel, 32 miles N.N.W. of Poitiers. Its streets are well laid out, and a beautiful promenade now occupies the site of an old fortress, destroyed in the beginning of the seventeenth century by order of Cardinal Richelieu. Some cloth, linens, and common lace are manufactured here; and a brisk trade in oil, white wine, and walnuts is carried on. This town was one of the first in France to embrace the reformed religion, and soon became a stronghold of the Protestant party. In 1634 it was the scene of the disgraceful execution of Grandiere, curate of Loudun, who was burnt at the stake by command of Richelieu. Pop. (1851) 4457.

LOUGHBOROUGH, a market-town of England, in Leicestershire, and a station on the Midland Counties' Railway, about 9 miles N.N.W. from Leicester. It is lighted with gas, and consists of five principal streets, meeting near the centre of the town, and lined with houses mostly built of brick. The chief buildings are,—the old parish church; the new church of Emmanuel; and Burton's school—a well-endowed institution, possessing two exhibitions at Jesus College, Cambridge. There are also other schools, several dissenting meeting-houses, a literary and philosophical society, a theatre, barracks, and a Roman Catholic convent. The principal articles of manufacture are, woollen and cotton hosiery, laces, and shoes. The trade of the town is much facilitated by the Loughborough canal that connects it with the River Soar. Market-day, Thursday. Pop. (1851) 10,900.

LOUGHREA, a market-town of Ireland, county of Galway, on the N. side of Loughrea Lake, about 20 miles E.S.E. from Galway. With the exception of the houses that skirt the Dublin and Galway road, the town is ill-built, and consists of narrow and irregular streets. It has a parish church, recently rebuilt, three Roman Catholic chapels, a nunnery, and a Carmelite friary, founded in 1300 by Richard de Burgh, Earl of Ulster. There are also bar-

racks, a union workhouse, and a bridewell. The inhabitants are chiefly occupied in tanning, brewing, and the linen manufacture. Market-day, Thursday. Part of the old wall that fortified the town still remains. Pop. (1851) 5238.

LOUHANS, a town of France, capital of a cognominal arrondissement in the department of Saône-et-Loire, on the left bank of the Seille, which is here navigable. The town is composed of antique and grotesque-looking houses, and its streets are irregular and dirty. From its position, however, between the Saône valley and Switzerland, it has gained a certain commercial importance. It has a number of flour-mills, and an extensive trade in cattle, horses, and grain. Pop. (1851) 3785.

LOUIS, the name of many kings of France. Louis I., surnamed "Le Débonnaire," was born in 778, succeeded his father Charlemagne in 814, as King of France and Emperor of the West, and died in 840. Louis II., surnamed "The Stammerer," was born in 846, succeeded his father, Charles the Bald, in 877, and died in 879. Louis VI., called "Le Gros," the son and successor of Philip I., was born in 1078, ascended the throne in 1108, and died in 1137. Louis VII., son of the preceding, was born in 1120, succeeded his father in 1137, and died in 1180. Louis IX., canonized as St Louis, was born in 1215, succeeded his father, Louis VIII., in 1226, and died of a pestilence in 1270. Louis XI., the son and successor of Charles VII., was born in 1423, ascended the throne in 1461, and died in 1483. Louis XII., the son of Charles, Duke of Orleans, was born in 1462, succeeded Charles VIII. in 1498, and died in 1515. Louis XIII., surnamed "The Just," was born in 1601, succeeded his father, Henry IV., in 1610, and died in 1643. Louis XIV., the son of the preceding, was born in 1638, ascended the throne in 1643, and died in 1715. Louis XV., the great-grandson and successor of Louis XIV., was born in 1710, was declared king in 1715, was crowned in 1722, and died in 1774. Louis XVI., the son of Louis the Dauphin, was born in 1754, succeeded Louis XV. in 1774, and was beheaded in 1793. Louis XVIII., the brother of the preceding, was born in 1755, assumed the title of King of France and Navarre in 1795, ascended the throne in 1814, and died in 1824. Louis Philippe, the son of the Duke of Orleans, was born in 1773, was elevated to the throne in 1830, abdicated the crown in 1848, and died in 1850. (See FRANCE.)

LOUIS, Sr, a city and river port in the state of Missouri, U.S. of North America, is situate on the right bank of the Mississippi, about 20 miles below the junction of the Missouri, and 1194 miles above New Orleans. N. Lat. 38. 37. 28., W. Long. 90. 15. 16. Next to New Orleans, this is the principal port on the Mississippi; and among the western cities it is second only to Cincinnati in population and wealth. The Upper Mississippi, Ohio, Missouri, and their numerous tributaries, furnish it with upwards of 8000 miles of connected water communication, and open up to it countries rich beyond description in mineral, vegetable, and animal products. The mineral resources of its immediate vicinity are very great, comprising iron, coal, lead, and probably copper. The town extends for nearly 7 miles along the curve of the Mississippi, and about 3 miles backward; but the dense portion of it is only about 2½ miles in length by 1½ in breadth. It stands on two plateaux of limestone formation, the one 20, the other 60 feet above the highest flood of the river. The ascent to the first plateau is rather abrupt; the second rises more gradually, and spreads out into an extensive plain, affording fine views of the city and river. The town is well and regularly laid out; the streets, with few exceptions, being wide, and intersecting each other at right angles. Front Street, Main Street, and Second Street run parallel to each other and to the river, and are the seat of the principal wholesale business. Fourth Street

Louhans
||
Louis.

Louis.

is the fashionable promenade, and contains the finest retail shops. The houses are well built and handsome, chiefly of brick, though limestone is sometimes used. The new court-house, a magnificent building, resembling in style the Capitol at Washington, is constructed of limestone, and occupies an entire square. The fronts are adorned with porticos, and in the interior is a rotunda lighted from the dome. Among the finest of the other buildings are,—the Roman Catholic cathedral, a number of the other churches, the market-house, arsenal, and several of the hotels and private residences. There are at present about 60 places of worship in St Louis, of which 12 are Roman Catholic, 12 Methodist, 8 Presbyterian, 5 Episcopalian, 2 Jewish synagogues.

The educational and literary institutions are numerous and efficient. The university of St Louis, organized in 1832, and under the direction of the Roman Catholics, is a well-ordered and flourishing institution, having, in 1855, 20 instructors, 175 students, and 15,400 volumes in library. The medical college connected with it is also in a very flourishing condition. The medical department of the Missouri college is also located here. The Mercantile Library Association, organized in 1846 and incorporated in 1851, has recently erected, at a cost of about L.20,000, a magnificent building, four storeys in height, having a library and reading-room, lecture-room, grand hall, &c. The benevolent institutions comprise several hospitals, asylums, &c. The city hospital, long distinguished for its excellent accommodation, has recently been found inadequate to the wants of a rapidly increasing population, and the erection of new buildings is in agitation. The marine hospital, sisters' hospital, the home for the friendless, designed for aged indigent females, and the house of refuge, are all valuable institutions. Of the Roman Catholic and Protestant orphan asylums, the former is under the direction of Sisters of Charity, the latter of Protestant ladies.

The city is supplied with water from the river, raised by means of steam engines into a reservoir 250 feet square by 15 feet deep, and capable of containing 5,000,000 gallons, and thence distributed over the city by about 36 miles of pipes. It is in contemplation to construct another reservoir, 540 feet in length, 250 in breadth, and 25 in depth, and capable of containing 52,000,000 gallons. Gas-works have recently been erected here, and about 33 miles of street pipes are now laid down.

The manufactures of St Louis, although still in their infancy, are of great importance, and rapidly increasing. The flour-mills are here more extensive than in any other city in the west. The product of the various mills for 1852 amounted to 393,184 barrels, and their daily capacity is estimated at 3000 barrels. Sugar refining is actively carried on; Belcher's sugar refinery being one of the largest in the Union. The vast mineral resources of the district are being taken advantage of, and the iron manufactures of St Louis already exceed those of any other city on the Mississippi, if not in the west. Chemicals, oils, and tobacco are among the more important of its other manufactures. It is, however, as a commercial city that St Louis is most important. The shipping owned in the district at 30th June 1852 amounted, according to the custom-house returns, to an aggregate of 37,861 tons, enrolled and licensed, of which 32,646 were steamers. The aggregate number of arrivals of steamers during 1852 was 3184.

St Louis was founded in 1764, but up to 1820 it contained only 4598 inhabitants, and in 1830 only 6694. In 1840 it had reached 16,469, and in 1850, 77,854, of whom 75,204 were free and 2650 slaves; 23,774 were natives of Germany, 11,257 of Ireland, 2933 of England, and 2450 of other foreign countries. An official return of the population of St Louis in 1855 gives the number of inhabitants in the city proper as 97,642, of whom 94,686 were free.

The entire population of the city and suburbs is estimated at nearly 120,000.

LOUIS, *St.*, a small island belonging to France, on the W. coast of Africa, Senegambia, at the mouth of the Senegal River, N. Lat. 16. 5., W. Long. 16. 32. It is low and sandy, about 2 miles long by half a mile in breadth, and nearly 5 miles from the debouchment of the Senegal. Situate on the island is a town and seaport of the same name, where the governor resides; it can only be reached by vessels of light burthen. Pop. of island, 15,000, of whom 800 are whites.

LOUISIANA, one of the United States of North America, is bounded on the E. by the state of Mississippi, W. by that of Texas, N. by that of Arkansas, and on the S. by the Gulf of Mexico. It extends from W. Long. 88. 50. to 94. 20., and its extreme southern point is in N. Lat. 28. 56., whilst its northern limit is in N. Lat. 33. The average length is about 240 miles, and the mean breadth rather more than 200 miles; the area being 46,431 square miles. The surface of Louisiana is low, and generally level, with some hilly ranges of slight elevation in the western part. The southern part of this state, from Lake Borgne to Sabine River, and from the Gulf of Mexico to Baton Rouge and Red River, is an alluvial tract of country, extending about 240 miles in length, by from 70 to 140 in breadth. It is intersected by numerous rivers, bays, creeks, and lakes, which divide the country into a great number of islands. Three-fourths of the state are destitute of any elevation which deserves the name of a hill. The pine woods generally have a surface of a very particular character, rising into fine swells, with table surfaces on the summit, and valleys from 30 to 40 feet deep. They do not present the aspect of a connected range, and are scattered over the country like the waves of an agitated sea. A range of hills commences by gentle undulations in Opelousas, rises gradually, and diverges towards the river Sabine. In the vicinity of Natchitoches it preserves a distance intermediate between the Sabine and Red Rivers, and increases in elevation to the western part of the state. A second line of hills, not far from Alexandria, commences on the N. side of Red River, and separating between the waters of that river and Dugdemona, unites with another chain of elevations which bound the alluvial plains of the Washita as bluffs, gradually diverging from that river as they pass beyond the western limits of the state. There are likewise some considerable hills beyond the Mississippi, and in some other parts the country is high; but, generally speaking, Louisiana is one immense plain, divided into pine-woods, prairies, swamps, and hickory and oak lands. The pine-woods have almost invariably a poor soil. The greater proportion of the prairies is second-rate land, and some of them are even sterile. A few, however, in Opelousas and those of Attakapas, possess great fertility. They are in general more level than those of the upper country. A very considerable extent of them has a cold clayey soil, with a hard crust near the surface. In other places the soil is of inky blackness, and in the hot and dry season it cracks into fissures of some inches in width. A considerable belt of these prairies, near the gulf, is low, marshy, and in rainy weather inundated. The bottoms are generally rich. Those of the Mississippi and Red Rivers are particularly so, and the vegetation there is remarkable for its size and luxuriance. The cotton on fresh lands of the richest quality reaches the size of a considerable shrub. The basin of Red River possesses extraordinary fertility, and the lower courses of this stream are noted for the production of cotton. The soil is said to derive its fertility from a portion of salt which is intimately mixed with it, and from its peculiar friability; and the darkish red colour which it bears, is to be traced to the presence of the red oxide of iron. All the branches of Red River, and they

Louis
||
Louisiana.

Louisiana.

are very numerous, partake of the character of the main stream. The richest tract, however, in the state is a narrow belt of land lying along the Mississippi on both sides, and extending from 150 miles above to 40 miles below New Orleans. It is from 1 to 2 miles in width, and lies below the level of the river when flooded, being defended by a dyke about 6 or 8 feet in height. West of the Mississippi there are some tracts of soil very fertile, and here the sugarcane thrives well. A considerable portion of Attakapas is of great fertility, as are smaller portions of Opelousas, which is, however, best adapted for a grazing country. The lands on the Washita River are black, like those on the Mississippi; and the alluvions on the lower courses of this stream furnish an admirable soil for cotton and other productions.

A very great proportion of the surface of this state is covered with prairies. The first that occur W. of the Mississippi are those which are included under the general name of Attakapas; a term implying "man-eater" in the language of the savages who formerly inhabited it, and who are said to have been cannibals. It is an immense plain of grass, stretching from the Atchafalaya on the N. to the gulf on the S., and is of great fertility. To the W. of this prairie occurs that of Opelousas, still larger than the former, and computed to contain nearly 8000 square miles. It is divided by various natural boundaries into a number of prairies, distinguished by separate names. The soil, though occasionally very fertile, is less so than that of Attakapas; but this deficiency is compensated by the greater salubrity of the climate, which is reckoned the healthiest in the state. There are here very considerable cotton plantations, and some of indigo. Some of the others are of great extent, and they all possess nearly the same characteristics. They are generally so level as to appear to the eye a perfect plain; but there occasionally occur swells and declivities, such as are sufficient to carry the water from them. The margin which borders on the gulf is commonly a wet marsh, covered with a luxuriant growth of tall reedy grass called cane-grass. In various parts of these prairies there are islands of timber lands. Wherever a bayou or stream crosses the prairie, it is marked with a fringe of timber; and here the soil is invariably rich, as well as at the points of the prairie; but towards the River Sabine it is less so.

Wheat and rye do not flourish here in general, but oats and barley succeed well; and maize grows luxuriantly on the alluvions and rich lands. The sweet potato (*Convolvulus batatas*) in the sandy soil attains the greatest perfection. They are of different varieties, and occasionally of a very large size, but all are extremely nutritive, and raised with ease in great abundance. The Irish potato is not so easily raised, and is only cultivated for eating during the early part of summer. The pumpkin and melon tribe flourish in this climate, and all the northern fruits come to perfection, with the exception of apples, which generally decay before ripening. Different kinds of figs grow in the greatest abundance, and the tree would appear to attain its largest size in this quarter. Along the whole shore of the gulf, and in some other places, the orange tree, sweet and bitter, flourishes, and the fruit is of the finest quality. The cultivated vine flourishes abundantly; and wild grapes, such as the summer, winter, fox, muscadine, and pine-wood grape, are abundant. There is an immense number of wild and cultivated flowering shrubs, which flourish in this region; and the abundance of mulberry trees holds out a prospect that the culture of silk will ere long form one of the branches of trade in this state. The timber trees on the bottoms are willow, cotton-wood, honey-eye locust, pawpaw, and buck-eye; on the rich uplands, elm, cucumber, ash, hickory, mulberry, black walnut, with abundance of grape vines; and on the second rate, or sandy uplands, white, pitch, and yellow pines, and various kinds of oak. As yet agriculture is only in its infancy, the principal ob-

Louisiana.

ject being not to produce a great variety of crops, but to obtain the greatest amount of the staple productions. Sugar and rice are the staples of the state in general S. of 30°, and cotton N. of that parallel; the latter, however, is extensively cultivated in every part of the state. Sugarcane is an abundant article of growth in Louisiana. It requires the richest soil, the mould of which should at least be a foot deep. There are three or four varieties or species, as the African, the Otaheitan, the West Indian, and the riband cane. The Otaheitan grows luxuriantly, and ripens considerably earlier than the West Indian; but it is said to contain only two-thirds of the saccharine matter of the other. The riband-cane is a new and beautiful species, which possesses the advantage of not requiring so long a season for ripening. Throughout the state the planters are turning their attention to the cultivation of the sugarcane; and in 1850 this state produced nine-tenths of the entire quantity raised in the Union. The rice is remarkably white, and yields abundantly. There is a great extent of land favourable for the production of the upland rice; and no limit can be assigned to the amount which might be raised. The cotton cultivated here is an annual plant, growing in the rich lands more than six feet in height, and the larger stalks of the size of a man's arm, throwing out a number of branches, on which form large and beautiful whitish-yellow blossoms. It is planted from March till the middle of May, in drill rows, six feet apart. The kinds of cotton cultivated are—Louisiana, green seed or Tennessee, and recently Mexican cotton. The green seed is not of so fine a quality, but it is less subject to the destructive malady called the rot. The Mexican is finer, and yields more abundantly. Sea Island cotton grows well upon grounds that have been exhausted by the continued cultivation of the other kinds. All the species exhaust the soil; but the seeds, which accumulate in prodigious quantities around the gins, furnish an admirable manure, which supplies the deficiency of nutriment. Indigo was formerly a prime object of attention amongst the planters, but the cultivation of it has been abandoned. The finest tobacco is raised, but it is not so profitable as sugar and cotton, although that which is cultivated in the vicinity of Natchitoches is said to equal the tobacco of Cuba. Louisiana in 1854 produced 346,635 hogsheads of sugar.

In 1699 a colony of Frenchmen was founded on the shores of Louisiana by M. D'Iberville. In 1712 the King of France granted to M. Crozart a charter, which included the whole of the territory of Louisiana; but after five years the charter was surrendered into the hands of the king. To the company founded in Paris by the notorious John Law was granted the great territory of Louisiana, as it had been surrendered by Crozart. By the failure of this company, Louisiana again reverted to the crown, by which it was held for some time; but in 1762 it was ceded to Spain, to prevent its falling into the hands of the English. In 1800 Bonaparte succeeded in inducing Spain to retransfer Louisiana to France; and in 1803 it was sold to the United States for 60,000,000 francs=12,500,000. In 1812 it was admitted as a member of the Union.

According to the present constitution, every white male person, twenty-one years of age and upwards, who shall have resided in the state twelve months, and in the parish for six months next preceding the election, has the right of voting. The legislature consists of a senate of 32 members, elected for four years, one half going out every second year; and a house of representatives of not less than 70, nor more than 100, elected for two years. The governor is elected for four years. The legislature meets annually, and the session lasts not more than 60 days.

The constitution provides that "free public schools shall be established throughout the state; the proceeds of lands granted for the purpose, and of lands escheated to the state,

Louisville shall be held as a permanent fund, on which six per cent. interest shall be paid by the state for the support of these schools." The number of schools in operation on an average eight months in the year, in 38 parishes, was 687; average attendance about 36,000, and number of teachers about 1000. According to the census of 1850, Louisiana had 306 churches, with accommodation for 109,615 persons. Of these, 125 were Methodist churches, accommodating 33,180; 77 Baptist, 16,660; 55 Roman Catholic, 37,780; 18 Presbyterian, 9150; 14 Episcopalian, 5210; 6 Union, 1350; 3 Christian, 1500; 3 Free, 675; 1 German Reformed, 500; 1 Jewish, 600; 1 Universalist, 1000; and 2 minor sects, 1650. The number of libraries was 10, with 26,800 vols.; and of these, 5, with 9800 vols., were public; 2, with 12,000 vols., school; and 3, with 5000 vols., college libraries. In 1810 Louisiana contained 76,556 inhabitants; in 1820, 153,407; in 1830, 215,739; in 1840, 352,411; and in 1850, 517,763;—of whom 141,244 were male, and 114,248 female whites; 7479 free coloured males, and 9983 free coloured females; and 125,874 male, and 118,935 female slaves.

LOUISVILLE, a city and river port of the United States of North America, capital of Jefferson county, Kentucky, on the left bank of the Ohio, opposite the falls. N. Lat. 38. 3., W. Long. 85. 30. This town, the most populous in the state, and one of the chief ports on the Ohio, is regularly laid out on a plain about 70 feet above the river. Several of the streets are two miles in length, running parallel with each other, and often ornamented with rows of trees. The chief public buildings are the town-hall, the court-house, the two colleges for law and medicine, St Paul's Episcopal church, and the blind asylum. Besides these there is an historical institute, and a mercantile library association possessing 5000 volumes. Louisville owes its present importance to the falls which occur here, and to the canal constructed to obviate this stoppage of the navigation. It is 2½ miles long, cut through limestone, and falls 22 feet by means of lockage. The depth, however, which is only 16 feet, has been found insufficient for the heavy river steamers; and consequently a ship-railway has been projected, by which the largest vessels may be brought round the falls on the Indiana side of the river. Vast quantities of provisions are brought into Louisville both by river and railway, but especially by the former. In 1855 the value of articles (including provisions and hard goods) imported into the town amounted to L.7,566,945; the chief articles being pork and bacon, beef, sugar, flour, feathers, hemp, bagging, and shingles. Most of these likewise form articles of export. The steamship building has much increased here, and now constitutes an important trade. In the year ending November 1855 there were 41 steamers launched from this port. In the year ending 31st December 1855, 93 steamers, of 28,705 aggregate tonnage, were registered. The manufactures of the place have also increased in number and extent. Bagging, flour, rope, wool, cotton, and tobacco manufacturing now employ a large number of the inhabitants, and copiously supply the export trade. Louisville was laid out in 1773, but it was not established as a town till 1780, when it received its name from the Virginian legislature, in commemoration of the alliance concluded between Louis XVI. of France and the Western Republic. Pop. (1840) 21,210, (1850) 43,196, and (1853) 51,726.

LOURDES, a town of South France, department of Hautes Pyrénées, on the right bank of the Gave-de-Pau, 24 miles S.E. of Pau. It is built on a steep elevation, which rises to the height of 511 feet, and is crowned by a fortress formerly possessed by the counts of Bigorre. The streets are as well laid out as the irregular nature of the ground will admit. Manufactures of handkerchiefs and flax are carried on, as well as a general trade in agricultural pro-

duce. Some remains of Roman fortifications are found here, and in the vicinity are several curious grottos. While in the possession of the English in the fourteenth century, it formed the centre point of their military operations, but was evacuated by them shortly after the treaty of Breigny in 1360. Pop. (1851) 4500.

LOUTH, a maritime county in the province of Leinster, in Ireland, bounded on the N. by the county of Down and the Bay of Carlingford, on the E. by the Irish Sea, on the S. by the county of Meath, and on the W. by the counties of Meath and Monaghan. It is the smallest county of Ireland, comprising an area of only 315 square miles, or 201,434 acres; of which 178,972 are arable, 15,603 uncultivated, 5318 in plantations, 728 in towns, and 813 covered by water. Of the 15,000 acres of uncultivated or coarse pasture land of unproductive nature, it is estimated that 3000 may be drained and tilled; 5000 may be drained for pasture; and 7000 acres of the elevated ground near the summit of the mountains must be considered incapable of improvement.

In the time of Ptolemy it formed part of the maritime district inhabited by the Voluntii. Afterwards it was known by the name of Argiall, Orgiall, or Uriell, which also comprehended the greater part of the counties of Meath, Monaghan, and Armagh. Its leading families of Irish extraction were the O'Carrolls and the M'Scanlans. It was conquered by the English under De Courcy in his progress northwards to Ulster, and formed one of the twelve counties into which King John divided that part of Ireland which acknowledged his authority, and was granted to De Courcy, and subsequently to De Lacy, as earls of Ulster. By De Lacy it was divided and subgranted among the families of De Verdon, Peppard, Taate, Bellew, Gernon, &c. It is now divided into the six baronies—Ardee, Drogheda, Upper and Lower Dundalk, Ferrard, and Louth, which are subdivided into sixty-one parishes, all in the archdiocese of Armagh, and two parts of parishes in the diocese of Clogher.

The southern part of the county is fertile and agreeably diversified by gentle undulations of surface. Proceeding northwards, it becomes more hilly, until, at its most northern extremity, it rises into the bold and picturesque mountains of Ravensdale and Carlingford, which in some places attain an elevation of nearly 2000 feet. The rivers are the Dee, the Clyde, the Fane, and the Castletown. None of them are navigable, being useful solely for irrigation and other purposes of rural economy. The Boyne, which forms part of the southern boundary of the county, is navigable for large vessels as far as Drogheda. The county has a considerable line of sea-coast, consisting chiefly of a sandy strand, except where it is broken by the projection of Clogher Head, a bold promontory, which, although only 180 feet in height, forms a striking feature from the adjoining flat sandy beach. The Bay of Dundalk extends beyond this point for seven miles at its mouth, indenting the coast for an equal distance inland. The Carlingford Mountains, bounding the northern extremity of the county, separate it from the bay of that name, which forms the line of demarcation both between the counties of Louth and Down and the provinces of Leinster and Ulster. This bay is deep and narrow, extending in length upwards of nine miles, with an average breadth of a mile and a half. It is navigable to Warrenpoint, near the town of Newry, and its shores on both sides are much admired for their bold and picturesque scenery. Immense beds of oysters, in high estimation amongst gastronomists for peculiar delicacy of flavour, occupy different localities in this bay.

The soil in the southern lowlands is well adapted for tillage, being composed of a rich vegetable mould resting on marl or on limestone, sometimes with a substratum of slate. The quality of the soil diminishes in agricultural value as

Louth.

Louth.

the land rises towards the N., and the summits of the mountainous district produce only heath and scanty herbage.

The mountains are composed chiefly of granite. On their borders hornblende and primitive greenstone are found in abundance, after which are exterior ranges of transition rock. The lower lands rest on a clay-slate formation. The line of separation between the granite and the clay-slate extends from Carlingford Bay, over the summit of the Ravensdale Mountains, into the county of Armagh. Flœtz limestone appears in the neighbourhood of Drogheda and Ardee. A lead mine was worked for a short period at Salterstown, near the sea-coast.

The returns of the population, taken at different periods, present the following results:—

1760.....	De Burgho.....	67,512
1792.....	Beaufort.....	57,750
1821.....	Parliamentary return.....	101,011
1831.....	Ditto.....	107,481
1841.....	Ditto.....	111,979
1851.....	Ditto.....	90,812

The county, though the smallest in Ireland, sent no fewer than twelve representatives to the Irish parliament. Two were returned for the county, two for the town of Drogheda, and two for each of the boroughs of Dundalk, Ardee, Carlingford, and Dunleer. The Act of Union reduced this number to four,—two for the county, one for Drogheda, and one for Dundalk; and this arrangement still continues.

The number of schools and of pupils attending them during the week ended 12th April 1851, was,—

Schools.	No. of Schools.	No. of Pupils.		
		Males.	Females.	Total.
National	48	2069	1940	4009
Church Education	14	258	209	467
Endowed	6	311	161	472
Boarding	3	11	95	106
Private	32	433	286	719
Parochial ..	8	108	118	226
Free.....	7	127	140	267
Industrial	1	...	7	7
Mission	1	2	3	5
Military	1	15	20	35
Workhouse	3	289	378	667
Gaol.....	1	62	26	88
	125	3685	3383	7068

The lands capable of cultivation are mostly kept in tillage. Potatoes, wheat, oats, and barley, raised according to the succession here stated, form the principal crops. In the northern districts oats are chiefly raised.

The total extent of land under each description of crop in 1855 and 1856 was:—

	1855. Acres.	1856. Acres.
Wheat.....	9,674	14,951
Oats	38,530	34,228
Barley, bere, rye, beans, and pease,	22,028	20,195
Potatoes	12,010	14,639
Turnips.....	9,235	9,027
Other green crops.....	2,548	2,615
Flax.....	190	219
Meadow and clover.....	17,286	18,131
Total.....	111,501	114,005

Sheep are most abundant in the hilly districts.

The quantity of live stock in the county in 1855 and 1856 was:—

	1855.	1856.
Horses	12,133	12,328
Cattle.....	32,107	31,481
Sheep.....	31,712	40,440
Pigs.....	14,232	12,017

Many parts of the county are well planted. The ash tree grows in the lower grounds to a great size. The coasts

furnish a constant supply of fish; and the flat shores abound with sea-fowl, especially barnacle, which, however, is not so highly esteemed for flavour as that of Wexford or Derry. The manufacture of coarse linens is carried on to a considerable extent.

Few counties can boast of so many remains of antiquity. There are two round towers,—one at Monasterboice, 110 feet in height, and in a state of excellent preservation, the other at Dromiskin, much decayed. At the former of these places there are also the remains of two small churches and of three finely sculptured crosses, one of them 18 feet high. Near the banks of a stream called the River of Balrichan, is a large artificial cave, accidentally discovered by the sinking in of a horse whilst ploughing. It consists of several narrow passages, the sides and top of which are formed of flag-stones. Some bones of large and small animals were found in it. About 2 miles from Dundalk are the ruins of a very ancient structure, which has some resemblance to the hull of an ancient galley. There are no traces of doors, windows, or loop-holes. The building has given rise to much antiquarian discussion. At Ballymascanlan is a cromlech called the Giant's Load, consisting of a rock 12 feet long and 6 broad, elevated on three upright stones. Near it is Castle Rath, surrounded by moats and lesser raths, and with a remarkable tumulus in its vicinity. The great mound of Castleguard, near Ardee, is 90 feet in height and 600 feet in circumference at its base. Its summit terminates in an area 140 feet round. It is well planted, and surrounded by a deep trench. At Faughart are the remains of an ancient intrenchment. The decisive battle which terminated in the defeat and death of Edward Bruce, by Sir John Bermingham, afterwards Earl of Louth, was fought near this place. The remains of castles are numerous. That of Carlingford, built by King John, occupies a commanding position on a rock projecting into the bay. Castletown stands within sight of the town of Dundalk. Terfeckan Castle, once the residence of the learned Archbishop Usher, is now in ruins. The county is equally remarkable for the number of its ancient monastic edifices. Mellifont, a Cistercian abbey, 5 miles W. of Drogheda, presents some remains equally remarkable for their beauty and singularity of architecture. Others are to be traced at Carlingford, Faughart, and Monasterboice. The principal towns of the county are Dundalk, Ardee, and Drogheda.

(11.5-11.)

LOUTH, a municipal borough of England, Lincolnshire, and a station on the Great Northern Railway, is situate on the River Ludd, 25 miles E.N.E. from Lincoln. The houses are mostly built of brick and roofed with slate, and the streets are clean, well paved, and lighted with gas. Louth has a guild-hall, a sessions-house, a house of correction, an assembly-room, several churches and chapels, almshouses, a dispensary, and a small theatre. The principal building is the church of St James, an edifice of the later English style, surmounted by an octagonal spire of 288 feet, and possessing an east window remarkable for its beautiful tracery. There is a richly endowed grammar school, founded by Edward VI., from whom the borough also received its charter. Louth is famous for its ale; and has manufactories of carpets, blankets, soap, and paper. By means of a canal, fed by the Ludd, and communicating with the Humber, it carries on a considerable traffic in corn and coals. Since the Reform Act, the borough has been divided into two wards, and governed by a mayor, six aldermen, and eighteen councillors. Markets are held on Wednesday and Saturday. In the vicinity are the ruins of a Cistercian abbey, founded in 1139 by Alexander, Bishop of Lincoln. Pop. (1851) 10,467.

LOUVAIN, an ancient town of Belgium, province of South Brabant, on the River Dyle, a tributary of the Scheldt, 15 miles E. by N. of Brussels. It consists of re-

Louth
||
Louvain.

Louviers. gular but ill-built streets, and is encompassed by an earthen rampart 90 feet high, which in some parts has been converted into boulevards. On the outside is a dry ditch of considerable depth; while here and there ruined bastions, said to have been erected by the Spaniards, stand at intervals on the wall. The town, though once a place of commercial importance, has been for many years decaying, and now presents a deserted appearance. It has, however, many public buildings of considerable interest. The town-hall, founded in 1448, and recently repaired, is a building of great beauty, embellished as it is with the finest chisellings, and ornamented with many sculptures. In its neighbourhood stands the cathedral, founded in 1040; and, in consequence of two destructive fires, re-erected in 1358. The sacristy of this church exhibits elaborate carving, and rises in a hexagonal form to the height of 30 feet. The wooden pulpit is likewise a fine specimen of carving, representing the conversion of St Paul. Many famous paintings of the old Flemish school also ornament the building. The other most notable edifices are,—the guild-hall, founded in 1317, the university, the picture-gallery, and the church of St Gertrude. The university was a distinguished school of Roman Catholic theology in the sixteenth century, and possessed large endowments. It was, however, suppressed by the French republic; but at the end of the French war it was re-opened by William of Holland. Its library contains 105,000 volumes. The only manufacture of importance carried on here is that of beer, which is accounted the best in Belgium, and of which there are about 200,000 casks brewed yearly. Some woollens, hosiery, hats, soap, and candles, are also manufactured here.

Louvain is a place of considerable antiquity, and by some is thought to have been founded by Julius Cæsar. The ruin of the old castle situate at the outskirts of the town is known by the inhabitants under the name of the Château de César, although it was not erected till 900 years after the death of Julius Cæsar. It was the residence at different times of Edward III. of England and Charles V. of Spain. In the fourteenth century Louvain was the chief town of Brabant, was very populous, and the principal seat of the woollen manufacture in Flanders. In 1382 a large number of the weavers were banished from the town in consequence of a disturbance. These mostly emigrated to England, where they recommenced the wool manufacture, which, under their care, soon became more important than it had ever been at Louvain. From this period the town gradually decayed. It was taken for the first time in 1792 by General Kleber, who commanded the forces of the French republic. Pop. (1850) 30,065.

LOUVIERS, one of the three principal cloth-manufacturing towns of France, and the capital of the arrondissement of the same name in the department of Eure, is advantageously situate on the River Eure, 17 miles S.S.E. of Rouen. It has 30 manufactories for cloth, and 19 spinning mills of woollen yarn, which employ about 12,000 persons in and around the town. The cloth manufactured at Louviers is remarkable for its fine quality; yet the town is being gradually outstripped by Elbeuf. Louviers is an old town, of which the newer part, on the right bank of the Eure, is well built; but the older part on the left is "constructed of wood, and traversed by narrow dirty lanes, where the working classes are huddled together in ignorance, demoralization, and wretchedness." The principal building in the town is the church of Notre Dame, erected in 1496. The chief factories are for the most part well built, and the machinery of admirable construction and arrangement. Its manufacture of fine cloths dates as far back as 1680; but in 1789 it produced only from 3000 to 4000 pieces annually, while at the present day it sends forth as much as from 30,000 to 40,000 pieces. There are also dyeworks, bleachfields, tannerics, and sugar refineries

in the town. Louviers suffered severely from the early wars between France and England. Taken by Henry V. of England in 1418, and retaken by the French in 1450, it sustained a protracted siege during the following year from the Duke of Bedford, who, after taking it, razed it to the ground. It was rebuilt ten years afterwards. Louviers has a civil and commercial tribunal, and a council of *prud'hommes*, and (in 1851) a pop. of 10,380.

LOVELACE, RICHARD, a poet, the son of Sir William Lovelace, of Lovelace Place, in Kent, was born in 1618. After receiving his education first at Charter House, and afterwards at Gloucester Hall, Oxford, he was presented at court, and was there much admired for his amiable disposition and handsome person. A zealous royalist, he became a colonel in the army of Charles I., and soon after the close of the civil war was the bearer of a petition from the county of Kent to the Long Parliament for the restitution of the king and the settlement of the government. For this bold deed he was imprisoned, but was soon liberated on a heavy bail. Having entered the French service in 1646 as commander of a regiment which he had raised, he was wounded at the battle of Dunkirk. On his return to England in 1648, he was again thrown into prison, and continued there till the king's death in 1649. In the same year was published his volume of Odes, Sonnets, and Songs, under the title of *Lucasta*, the fictitious name of a lady who had reciprocated his attachment, but in consequence of a false report of his death at Dunkirk, had been married to another. Thrown into a state of melancholy by this latter circumstance, and penniless through his vast expenditure in the royalist cause, he passed his latter years in wretchedness. Wood relates that he died of consumption in 1658 in a miserable alley near Shoe Lane. Lovelace also wrote *The Scholar*, a comedy, and *The Soldier*, a tragedy. In 1659 appeared his *Posthume Poems*; and these, along with his *Lucasta*, were reprinted in 1817 and 1818, 12mo. A few of his lyrics, including his well-known lines, *To Althea from Prison*, are free from the crude conceits and disjointed versification of the majority of his poems. Pervaded by the quaint and deformed imagery peculiar to that age, they are yet raised to the rank of true lyrical poetry by their sweetness of rhythm, simplicity of thought, and tender and elevated feeling.

LOWELL, an important manufacturing town of the United States of North America, one of the capitals of Middlesex county, Massachusetts, on the right bank of the Merrimack River, at its junction with the Concord, 25 miles N.N.W. of Boston. Although the site of the town has considerable inequality of surface, its streets are regularly laid out, and intersect each other at right angles. The private residences are spacious, and many of them elegant buildings. Amongst the public edifices, the chief are,—the court-house, the mechanics' hall, a sick hospital for operatives, and a market-house. The literary institutions of the town are very efficient, and have been of considerable service to the community. The mechanic association, incorporated in 1825, has a valuable library of about 6000 volumes, and a scientific apparatus; while the city school library contains 9500 volumes, and is open to all on a small yearly payment. The great advantage which Lowell enjoys for a manufacturing town is derived from a descent of 30 feet made by the Merrimack, and known as the Pawtucket Falls, which, by means of canals and locks, provides abundance of water-power. Besides these there is a capacious reservoir, placed on an elevation eastward of the city, which furnishes an immense supply of water at all times in case of fire. The principal goods manufactured here are cotton, wool, and iron. The first is made into cotton cloth and calico; the second into carpets, cloth, and coarse stuffs; and iron into machinery and wire fences. Besides these, however, bleaching is carried on

Lovelace
||
Lowe

Lower
||
Lowestoft.

extensively, as well as the preparation of dyes, glue, and other essentials of the cotton and wool manufactures. In January 1855 there were 12 manufacturing companies in Lowell, owning 52 mills, and working 371,838 spindles, and 11,407 looms. The aggregate quantities produced every week were 2,230,000 yards of cotton cloth, 30,000 yards of woollen cloth, 25,000 yards of carpeting, and 50 rugs. In the same year, £2,900,000 of capital was invested in the whole manufactures of the place; while the number of hands employed amounted to 8723 females, and 4542 males. Every attention is paid by the mill-owners to the health and morality of their operatives. One of the best proofs of the general good conduct of the mill-workers here is shown in the large amounts deposited by them in the savings-bank; and also in the interest they take in the literary and scientific associations connected with the factories. About a third of the inhabitants are of Irish extraction. The site of Lowell was first inspected in 1821 by several gentlemen, for the purpose of erecting a calico printing mill in New England. The building was immediately commenced, and in 1823 its machinery was set in motion. In 1826 it was established as a town, and named after Francis Lowell, an enterprising manufacturer of Boston. In 1836 it was raised to the rank of a city. Pop. (1840) 20,796, (1850) 33,335, (1854) about 38,000.

LOWER, RICHARD, an eminent English physician in the seventeenth century, was born in Cornwall, and educated at Westminster School and Oxford. He afterwards studied medicine, and practised under Dr Thomas Willis, whom he instructed in some parts of anatomy, especially when the latter was writing his *Cerebri Anatome*. In 1674, Lower, along with Dr Willis, discovered the medicinal waters at Ashop, in Northamptonshire, which, upon their recommendation, became very much frequented. In 1666 he followed Dr Willis to London, practised physic under him, and became a fellow of the Royal Society and also of the College of Physicians. In 1669 he published his *Tractatus de Corde*; and after the death of Dr Willis in 1675, he was esteemed the most eminent physician in London. Lower died in 1691.

LOWESTOFT, a market-town on the E. coast of Suffolk, 114 miles N.E. from London by road, and 149 by railway. The town, which is a place of great antiquity, stands on the top of a cliff facing the sea, from which it presents a remarkably picturesque appearance. It consists of a principal street, nearly a mile in length, with several smaller ones leading off from it. The parish church, about half a mile west of the town, is large and handsome, and contains several interesting monuments of antiquity. Potter, the distinguished Greek scholar, is buried in the churchyard. There is also a chapel of ease in the place, and chapels for Wesleyans, Independents, and Baptists. There is a free school and a national school in the town; besides a town-hall, a theatre, a lunatic asylum, and two lighthouses—one on the upper cliff, and another on the beach at the south end of the town. The roadsteads are sheltered by the Corton and Newcome Sands. Lowestoft has recently risen into considerable repute as a bathing place, from the peculiar adaptation of its sands for that purpose. Sir Samuel M. Peto purchased the harbour in 1844, and originated measures for the deepening of Lake Lothing, and for the general improvement of the port and town. The same gentleman further laid the town under considerable obligations to him by the construction of a branch railway from Reedham to Lowestoft. The principal manufactures are those of rope and twine; and a great number of the inhabitants are engaged in the fisheries and in fish-curing for the markets of London and Norwich. The shipping returns, given on the 31st December 1855, show the number and tonnage of the sailing vessels registered at Lowestoft as follows:—101 sailing vessels, with a

tonnage of 4353; and 7 steam-vessels, with a tonnage of 1297. Lowestoft communicates with Denmark by steam during the season. Pop. (1851) 6580.

LOWICZ, a walled town of Poland, about 45 miles W.S.W. of Warsaw, on the Bzura, one of the feeders of the Vistula. It has an old castle, cavalry barracks, three churches, several monasteries, a Piarist college and gymnasium, a normal school, and an hospital. There are some manufactories of refined wax in the place; and it carries on a considerable trade in horses and cattle. The principal branches of industry, however, are linen-weaving and tanning. It was formerly the capital of a principality. Pop. 7100.

LOWTH, DR ROBERT, Bishop of London, the son of Dr William Lowth, was born at Buriton, in Hampshire, on 28th November 1710. From Winchester school he passed, in 1730, to New College, Oxford; and in 1737 became master of arts. He remained at the university, devoting himself to the cultivation of his fine talents, long concealed by the veil of his native modesty, but now slowly becoming visible to the world. Elected professor of poetry in 1741, he was re-elected in 1743, and in this capacity he delivered his lectures *De Sacra Poesi Hebræorum*. Bishop Hoadley collated him in 1744 to the rectory of Ovington, in Hampshire; and nine years afterwards to the rectory of East Woodhay, in the same county. He had also appointed him, in 1750, Archdeacon of Winchester. In 1754 Lowth received the diploma of D.D. from the University of Oxford. He had travelled in 1749 with Lord George and Lord Frederick Cavendish, and had thus been introduced to their kinsman, the Duke of Devonshire. Accordingly, when this nobleman repaired to Ireland, in 1755, as lord-lieutenant, Lowth accompanied him as his first chaplain. Immediately after this he was presented to the see of Limerick, an appointment which he exchanged with Dr Leslie for the prebend of Durham and rectory of Sedgfield. In 1765 he was elected a fellow of the Royal Society; and in the subsequent year was appointed successively to the see of St David's and to that of Oxford. He became Bishop of London in 1777; and in 1783 declined the primacy offered to him by George III. After enduring with great patience and fortitude a severe and protracted attack of the stone, he died at Fulham on 3d November 1787.

Bishop Lowth's first great publication was his *Prælectiones de Sacra Poesi Hebræorum*, Oxford, 1753, 4to; 1763, 8vo; republished, with valuable notes by J. D. Michaëlis, 1770, 8vo, and translated into English by Dr Gregory, 1787. These prælections, discussing a fresh and interesting subject, and written in remarkably pure Latin, were favourably received by the learned, both at home and abroad. His *Life of William of Wykeham*, published in 1758, shows with what skill and patience he could arrange a chaos of facts gathered from "records, registers, manuscripts, and other sources." In 1778 appeared his greatest work, *A Translation of Isaiah*, accompanied by a dissertation, and notes critical, philological, and explanatory. It is marked by the most critical knowledge of the character, and a full appreciation of the spirit, of eastern poetry. The 13th edition of this work appeared in London in 1842. Lowth also engaged with Warburton in a war of pamphlets, touching the book of Job, and for bitterness of spirit did not fall one whit behind that merciless controversialist. An *English Grammar* which he published in 1762, was in great repute in his own time, but has long since fallen into neglect. A similar popularity in the case of his poetical pieces was followed by a similar fate. Several of his sermons were published at different times, and have recently been reprinted, along with other remains, by P. Hall, London.—In the high offices which he latterly held, Bishop Lowth consulted the best interests of the church by endeavouring to supply her vacant preferments with the most meritorious in the profession.

Lozère.

LOWTH, *Dr William*, a learned divine, the son of an apothecary, was born in London in 1661. He received his rudimentary education at a school in his native city; and having entered St John's College, Oxford, in 1675, became master of arts in 1683, and bachelor in divinity in 1688. Seeing his great worth and learning, Dr Mew, Bishop of Winchester, made him his chaplain, and conferred upon him, in 1696, a prebend in his own cathedral; and in 1699 the rectory of Buriton, in Hampshire. Lowth now devoted his whole time to the duties of his profession. In his thorough study of theology, he ranged over the entire field of Latin and Greek literature, both ecclesiastical and profane, collecting many valuable notes, critical and philological. Some of these he afterwards contributed to Potter's edition of *Clemens Alexandrinus*, to Hudson's *Josephus*, to Reading's *Ecclesiastical Historians*, and to the *Bibliotheca Biblia*. His advice, also, was largely used by Chandler, Bishop of Durham, while he was engaged in writing his *Defence of Christianity*, and his *Vindication of the Defence*. More admirable, however, than even his great erudition, was Lowth's private character. His piety, ever active and benevolent, was the living embodiment of the earnest instruction he delivered from the pulpit. He died in 1732. One of his sons was Dr Robert Lowth, the subject of the preceding article. Dr Lowth's principal works are:—*A Vindication of the Divine Authority and Inspiration of the Old and New Testaments*, Oxford, 1692, 12mo, London, 1699; *Directions for the Profitable Reading of the Holy Scriptures*, London, 12mo, 1708, 1726; and *Commentaries on the Prophets*, 1765.

LOXA, a town of Spain. See **LOJA**.

LOXA, or *Loja*, a town of South America, in the republic of Ecuador, and department of Assuay, capital of the province of the same name, is situate in a valley of the Andes Mountains, 6768 feet above the level of the sea, in S. Lat. 4., and W. Long. 79. 24. It has an extensive trade in cinchona bark, obtained in the mountain forests to the E. of the town, and is considered to be of the finest quality. Pop. 10,000.

LOYOLA, **IGNATIUS**. See **JESUITISM**.

LOZÈRE, a department of France, formed from Gévaudan, a part of the old province of Languedoc, is bounded on the N. by the departments of Cantal and Haute-Loire, E. by those of Ardèche and Gard, S. by that of Gard, and on the W. by that of Aveyron. It is situate between N. Lat. 44. 7. and 44. 56., and E. Long. 3. and 4.; and is 65 miles long and 44 broad, with an area of 1995 square miles. This department takes its name from one of the summits of the Cévennes, which traverse it in the N. and E. The Margeride and Aubrac summits in the N. and W. belong also to this extensive range of mountains, which, with their traces of extinct volcanoes, precipitous cliffs, beautiful cascades, and stalactite caverns, present some of the most picturesque and delightful scenery. These mountains slope toward the Rhone, the Loire, and the Garonne, and form part of the basins of those rivers. The principal feeders of the Rhone are the Cèze (in which gold has been found), the Gard with its tributaries, and the Chassezac, which joins the Ardèche before reaching the Rhone; of the Loire, the Allier, with its tributaries the Chaperoux and the Ance; of the Garonne, the Lot, with its tributary the Truyère, and the Tarn, with its tributaries the Tarnon and the Jonte. None of these rivers are navigable in this department. The chief minerals are iron, copper, and lead, found mainly in Bagnols and Chaldette. Industrial manufactures are almost entirely confined to woollen and silken stuffs. The department is agricultural, but is one of the poorest and most thinly peopled of all France. The soil of the Montagne district in the N. is chiefly of a basaltic and granitic nature, and produces only hay and rye;

that of the Causses district, in the centre, is calcareous, and is the most fertile in the department, yielding wheat, barley, oats, hay, and fruits; that of the Cévennes district, in the S. and S.E., is of a schistose nature, and grows chestnuts, potatoes, and mulberries. The wine is scarce and of a bad quality. Some attention is given to the rearing of the silk-worm and of sheep. The climate is generally severe, and the temperature variable; the winters are long and cold, and a great quantity of rain falls throughout the year. The towns are small and badly built, and the roads are but few and generally in a wretched condition. There are 5 Calvinistic churches in the department, 8 churches belonging to the national religion, and 17 schools. There are 3 tribunals of first instance, having the court of appeal at Nîmes, 1 college, 1 normal school, 1 superior communal school, 591 elementary schools, of which 216 are communal. Lozère belongs to the tenth military division of France, that of Montpellier. Its chief town is Mende, with a pop. of 6944.

There are three arrondissements in this department, subdivided as follows:—

	Cantons.	Communes.	Pop. in 1851.
Mende.....	7	63	49,361
Marvejols.....	10	78	53,918
Florac.....	7	52	41,426
	24	193	144,705

LÜBECK, one of the free cities of Northern Germany, and the capital of a small territory, is situate on a gentle ridge between the rivers Trave and Wakenitz, 10 miles from the mouth of the former at Travemünde, and 86 miles N.E. of Hamburg. Lübeck is the capital of the four free or Hanseatic towns, and the seat of their supreme court of appeal. The court consists of six members, one of whom is chosen by each of the free towns; Frankfort and Bremen nominate the fifth; while the sixth is named alternately once by Lübeck and twice by Hamburg. The president is chosen annually by the senates of the four towns.

The present city of Lübeck was founded in 1143 by Adolphus II., Count of Holstein and Schaumburg, by whom it was ceded in 1158 to Henry Duke of Saxony, surnamed the Lion. In 1226 it was made a free imperial city by Frederic II. At this time it was an important commercial city, and was rapidly increasing. In 1241 it entered into treaty with Hamburg, and thus laid the foundation of the Hanseatic League, of which it became the head about 1260. For four centuries Lübeck continued in a flourishing condition, and is said to have at one time contained 200,000 persons. After the dissolution of the league, which took place in 1632, it gradually fell into decay, and has never again attained its former importance. After the battle of Jena in 1806, the Prussian general, Blücher, with the remains of his army, took refuge in Lübeck, which was then stormed by the French, and sacked and pillaged for three days. In 1810 it was annexed to the French empire, and so remained till after the battle of Leipzig in 1813, when it was restored to its political independence, and subsequently joined the German Confederation as a free city. It has one vote in the full council; but in the select council it has only one in conjunction with the other free towns. Lübeck is one of the most picturesque old towns in Germany. Its streets are generally straight and regular, and its public buildings, which are mostly of brick, have undergone little change since the fifteenth century. Many of the houses are in the old-fashioned style, with their quaint gables towards the street; and not a few of them are remarkable for the richness of their architecture. The old ramparts of the town have been laid out in public walks. The finest building in Lübeck is the Marienkirche, founded in 1304. It is in the pointed Gothic style, constructed almost entirely of brick, and surmounted by two towers with spires rising to the height of 430 feet. It has three naves; the roof of the centre one rising to the unusual height of 134 feet. It contains

Lübeck.

Lubieniet-
ski
||
Lubnū.

numerous monuments and paintings,—the latter by Holbein, Vandyck, Overbeck, &c. The "Dance of Death," dated 1463, is remarkable as representing the costumes of the period. This church possesses a very fine organ, and has also a curious old astronomical clock, constructed in 1405. The Domkirche, or cathedral, built between 1170 and 1341, is almost entirely of brick, and has two towers surmounted by spires 300 feet high. It contains numerous monuments to bishops and others connected with Lübeck. The screen of the choir is a masterpiece of wood-carving of the early German school. In one of the side chapels is a painting by Memling representing the Passion of our Saviour in twenty-three distinct groups. The town-house, on the market-place, is a curious old Gothic brick building, completed in 1517. Here in ancient times deputies from the 85 cities in Germany composing the Hanseatic League, held their sittings. The educational and charitable institutions are numerous; besides which there are an exchange, mint, arsenal, public library with 37,000 volumes, and a theatre.

Lübeck is still a place of considerable commercial importance. It trades largely with Hamburg by means of the Trave and a canal, and also with Russia, Denmark, Sweden, and Finland. A branch line connects it with the Hamburg and Berlin Railway. Regular steam communication is kept up with Copenhagen, Stockholm, and St Petersburg. Vessels drawing not more than 9 feet of water can come up to the town, but larger vessels load and unload by means of lighters at Travemünde, between which and Lübeck small steamers are constantly plying. The chief exports are,—corn, cattle, wool, iron, and timber; imports,—wines, silks, cottons, hardware, colonial products, and dye-stuffs. In 1855, 972 vessels, carrying 55,266 lasts, entered; and 958 vessels, carrying 54,246 lasts, left the port.

The manufactures are numerous, but not large or important. Among the chief are woollen, linen, cotton, and silk goods; tobacco, soap, paper, playing-cards, musical instruments, hats; and iron, copper, and brass wares.

The territory subject to Lübeck consists of a district of about 80 square miles immediately adjacent to the city, of several small detached portions surrounded by Holstein; and of a portion of the Vierlande district; amounting in all to 127 square miles. The total population in 1851 amounted to 54,166 persons, of whom 26,096 were in the town.

LUBIENIETSKI, STANISLAUS, one of the chiefs of the Socinians in Poland, was born at Cracow in 1623. Becoming minister of a church at Lublin, he advocated the opinions of his sect so boldly that he provoked the enmity of the Jesuits, and was forced to flee to Hamburg. There, it is said, he was destroyed by poison in 1675. Lubienietski wrote *Historia Reformationis Polonicae*, Freistadt, 1685. His chief work is his *Theatrum Cometicum*, Amsterdam, 1667; in which, after giving a minute account of all the comets previous to 1665, he endeavours to prove from their history, that if they portend anything whatever, they foretell both evil and good, and not evil alone, as the common opinion runs.

LUBLIN, a city of Poland, the capital of the province of Lublin, is situate on the left bank of the Bistritz, 95 miles S.E. from Warsaw. Formerly fortified, the town is still surrounded by walls and ditches. It consists of houses built for the most part of wood and irregularly grouped, and is divided into two parts, the upper and the lower. The chief buildings are an old citadel, the cathedral of St Michael, the Sobieski Palace, a Piarist college, and several churches. There are also monasteries, a synagogue, and several educational and charitable institutions. Lublin is one of the chief seats in Poland of the coarse woollen and cotton manufacture; and trades in corn, cloth, and Hungarian wine. It is the see of a bishop, and has a court of appeal. Its three great annual fairs, each lasting a month, are frequented by Turks and Armenians. Pop. about 15,000.

LUBNŪ, an old town of Russia, in the government of

Luc.

Poltava, the capital of a circle of the same name, is situate on the Sula, about 80 miles W.N.W. from Poltava. Besides some churches and a veterinary institution, it has a small botanic garden. Lubnū was formerly so strongly fortified as to withstand a long siege from Charles XII. of Sweden. Pop. about 6000.

LUC, JOHN ANDRÉ DE, a natural philosopher of great merit and celebrity, born at Geneva on the 8th of February 1727, was the son of James Francis de Luc, descended from a family which had emigrated from Lucca and settled at Geneva in the fifteenth century.

His father was the author of some very respectable publications in refutation of Mandeville and other sceptical writers; and he had the means of giving his son an excellent education, although he found it convenient to establish him in a commercial engagement, which principally occupied the first forty-six years of his life, without any other interruption than that which was occasioned by some journeys of business into the neighbouring countries, and a few scientific excursions among the Alps. During these, however, he collected by degrees, in conjunction with his brother William Antony, a splendid museum of mineralogy and of natural history in general; which was afterwards increased by his nephew, André De Luc. He at the same time took his share of the public business of the state, as one of the Council of Two Hundred; and he is still remembered with respect by his fellow-citizens, though he revisited them but once, and that for a few days only, after his emigration, which was the consequence of some unexpected misfortunes in commerce. These he bore with fortitude, and rather rejoiced than lamented at the change in his pursuits, when he removed to England in 1773. He was made a fellow of the Royal Society in the same year, and was appointed reader to the queen; a situation which he continued to hold for forty-four years, and which afforded him both leisure and a competent income. In the latter part of his life he obtained leave to perform several tours in Switzerland, France, Holland, and Germany. In this last-mentioned country he passed six years, from 1798 to 1804; and after his return he undertook a geological tour through England. When he was at Göttingen, in the beginning of his German tour, he received the compliment of being appointed honorary professor of geology in that university; but he never entered upon the active duties of a professorship. He was also a correspondent of the Academy of Sciences at Paris, and a member of several other scientific associations.

His favourite studies were geology and meteorology. The situation of his native country had naturally led him to contemplate the peculiarities of the earth's structure, and the properties of the atmosphere, as particularly displayed in mountainous countries, and as subservient to the measurement of heights. He inherited from his father a sincere veneration for the doctrines of Christianity, and a disposition to defend the Mosaic account of the creation against the prevailing incredulity of the age. His royal patroness was most anxious to encourage and promote his labours in this field; and he is universally allowed to have had great success in removing the specious objections which had been advanced by his antagonists against the comparatively recent formation of the present continents. The testimony of Cuvier is sufficient to establish his character in this capacity, and to place him, at the same time, in the first rank of modern geologists. His original experiments relating to meteorology are, however, not less valuable to the natural philosopher; and he discovered many facts of considerable importance relating to heat and moisture. He noticed the disappearance of heat in the thawing of ice, about the same time that Black founded on it his ingenious hypothesis of latent heat. He ascertained that water was more dense about 40° of Fahrenheit than at the temperature of freezing, expanding equally on each side of the

Luc.

maximum; and he was the original author of the opinion since re-advanced by Mr Dalton, that the quantity of aqueous vapour contained in any space is independent of the presence or density of the air, or of any other elastic fluid; though it appears difficult to reconcile this opinion with some of the experiments of our author's great rival, Saussure, a philosopher who, as he very candidly allows, made, in many respects, more rapid progress in hygrometry than himself. De Luc's comparative experiments on his own hygrometer and on Saussure's, show only that both are imperfect; but it may be inferred from them, that a mean between both would in general approach much nearer to the natural scale than either taken separately. It appears also probable that Saussure's is rather less injured by time than De Luc's, which has been found to indicate a greater degree of mean moisture every year than the last.

De Luc was a man of warm feelings, and of gentle and obliging manners, fulfilling on all occasions the various duties of a husband, a father, a master, and a friend; at the same time that his literary and scientific merits, and his unremitting attention to the service of the queen, insured her respect and her kindness. He saw her daily for many years, and in his last illness, which was long and painful, she showed him repeated marks of benevolent regard. He died at Windsor on the 7th of November 1817, leaving a variety of works, which will long be remembered in the scientific world.

1. Recherches sur les modifications de l'Atmosphère, 2 vols. 4to, Geneva, 1772; 4 vols. 8vo, Par. 1784. This contains many accurate and ingenious experiments upon moisture, evaporation, and the indications of hygrometers and thermometers, applied to the barometer employed in the measurement of the height of mountains.

2. Relation de différens Voyages dans les Alpes de Faucigny, 12mo, Maestricht, 1771. This relation was written principally by Dentand, who accompanied the two De Lucs in these expeditions.

3. Account of a new Hygrometer, *Phil. Trans.*, 1773, p. 404. Like a mercurial thermometer, with an ivory bulb, which expanded by moisture, and caused the mercury to descend.

4. Rules for measuring Heights by the Barometer, *Phil. Trans.*, 1771, p. 158. The first correct rules that had been made public.

5. Barometrical observations on the depth of the mines in the Harz, *Phil. Trans.*, 1777, p. 401. Examples of the application of the rules.

6. An Essay on Pyrometry and Arcometry, *Phil. Trans.*, 1778, p. 419. A paper containing many valuable remarks on physical measures in general.

7. Lettres physiques et morales sur l'Histoire de la Terre, 6 vols. 8vo, Hague, 1778. Dedicated to the Queen; relating particularly to the appearance of mountains, and to the antiquity of the human race; explaining the six days of the Mosaic creation as so many periods preceding the epoch of the actual state of the globe; and attributing the deluge to the filling up of cavities supposed to have been left void in the interior of the earth. The whole work is intermixed with interesting observations on men and manners.

8. A second paper concerning some Barometrical Measurements in the Mines of the Harz, *Phil. Trans.*, 1779, p. 485.

9. Lettres sur quelques parties de la Suisse, 8vo, 1781. Also addressed to the Queen.

10. Nouvelles idées sur la Météorologie, 2 vols. in 3, 8vo, Lond. 1787. A very valuable collection of observations and experiments, including some original remarks on electricity.

11. Several papers on Hygrometry, on Vapour, and Rain, on Meteorology in general, on Expansion, and on Refraction, in *Rosier's Journal de Physique*, xxx. xxxii. xxxvi. xxxvii. xliii.

12. Some letters on the Physical History of the Earth, in the *Monthly Review*, enlarged, especially June 1790, and vol. ii. appendix.

13. On Hygrometry, *Phil. Trans.*, 1791, pp. 1, 389. In one of these very important papers the whalebone hygrometer is described.

14. On Evaporation, *Phil. Trans.*, 1792, p. 400. Amongst the fundamental principles laid down in this paper, the independence of vapour and air is asserted.

15. Lettres sur l'Histoire physique de la Terre, 8vo, Par. 1798. Addressed to Professor Blumenbach, and published by Mr Emery, a clergyman at Paris. The substance had already appeared in the *Journal de Physique*, for 1790, 1791, and 1798. We find in this volume an essay written for a prize at Haarlem in 1791, but without success, on the existence of a General Principle of Morality. It

contains an interesting account of some conversations of the author with Voltaire and Rousseau.

16. Lettres sur l'Education religieuse de l'Enfance, 8vo, Berlin, 1799.

17. Bacon tel qu'il est, 8vo, Berlin, 1800. Showing the bad faith of the French translator, who had omitted many passages favourable to revealed religion.

18. Précis de la Philosophie de Bacon, 2 vols. 8vo, Paris, 1802. Giving an interesting view of the progress of natural science.

19. Lettres sur le Christianisme, Berlin and Hanover, 1801, 1803. A correspondence with Mr Teller.

20. Introduction à la Physique terrestre par les Fluides expansibles, 8vo, Par. 1803.

21. Traité élémentaire sur le Fluide Galvanique, 8vo, Paris, 1804.

22. A paper on Lavas, *Journal des Mines*, cxv., Nicholson, xx.

23, 24. Several articles in the *Brit. Critic* and in the *Monthly Mag.*

25. Traité élémentaire de Géologie, 8vo, Paris, 1809; also in English, by Delafite, the same year. This volume is less strictly introductory to geology than the *Lettres sur la Terre*. It is principally intended as a refutation of the Vulcanian system of Hutton and Playfair, who deduced the changes of the earth's structure from the operation of fire, and attributed a higher antiquity to the present state of the continents than is required in the Neptunian system adopted by De Luc after Dolomieu.

26. He sent to the Royal Society, in 1809, a long paper on separating the chemical from the electrical effects of the pile, with a description of the electric column and aerial electroscope, in which he advanced opinions so little in unison with the latest discoveries of the day, especially with those of the president of the society, that the council probably thought it would be either encouraging error or leading to controversy to admit them into the *Transactions*. He had, indeed, on other occasions shown somewhat too much scepticism in the rejection of new facts; and he had never been convinced even of Mr Cavendish's all-important discovery of the composition of water. The paper was afterwards published in Nicholson's *Journal* (xxvi.), and the dry column described in it was constructed by various experimental philosophers. It exhibited a continual vibrating motion, which was made more sensible by the sound of a little bell, struck by the pendulum at each alternation; and the vibration was more or less rapid according to the state of the atmospherical electricity, and according to other circumstances affecting the column: but the motion ceased at last after a continuance of several months, or perhaps years. There are also papers in volumes xxi. xxii. xxvii. xxxiii. xxxiii. and xxxv., mostly on electricity and galvanism, together with one on hygrometry, a letter to Bode on comets, and a fanciful theory of the origin of the heat derived from compression. Some of them are dated from Ashfield, near Honiton, in Devonshire.

27. In the *Philosophical Magazine*, volumes xxxv. xlii. xliii. and xlv., there are also some papers on electricity and geology, especially on that of St Michael's Mount, of Vesuvius, and of Northumberland; and a note on the sympathetic vibrations of the pendulums of two clocks placed near each other.

28. Geological Travels in the north of Europe, 8vo, Lond. 1810.

29. Geological Travels in England, 2 vols. 8vo, Lond. 1811.

30. Geological Travels in Switzerland and Germany, 2 vols. 8vo, Lond. 1813.

31. An Abridgement of Geology, published in 1817, when he was in his ninetyeth year, is mentioned as one of his best works; but it seems to have been only a republication or a translation of some former treatise, perhaps the *Traité Élémentaire*.

(*Philosophical Magazine*, November 1817; Monod and Weiss, in the *Biographie Universelle*, tome xxv. 8vo, Paris, 1820.) (t. v.)

LUCANIA, a district of Southern Italy, extending from the Tyrrhenian Sea on the W. to the Gulf of Tarentum on the E., was bounded on the S. by the Brutians, on the N. by Apulia and Samnium, and on the N.W. by Campania. It derived its name from the Sukanians, a Samnite tribe, who in the third century before Christ, advancing gradually southward, waged an aggressive war with the Oenotrians and the Chones, the original inhabitants of the district, until, after the lapse of less than a century, they had advanced their conquest to the southern extremity of the peninsula. The Brutians, however, soon revolting, drove them back within the limits of the district which they afterwards occupied. Lucania was comprised in the third region of Augustus. One of the wildest parts of Italy, it sent forth from its extensive mountain forests wild swine for the markets, and numerous bears for the amphitheatres of Rome. Its chief rivers, the *Silarus* (Sele), the *Aciris* (Agri), the

Lucania.

Lucanus. *Casuentus* (Basiento), and the *Bradanus* (Bradano), all rise in the Apennines. The first flows westward into the Tyrrhenian Sea, the rest flow eastward into the Gulf of Tarentum. Of the towns, those along the coasts were nearly all of Greek origin, and maintained their independence long after the Lucanians had subdued the rest of the district. Studding the E. shore were *Metapontum*, *Heraclea*, *Siris*, and *Thurii*. On the W. coast stood *Laus Blanda* (Maratea), *Buxentum* (Policastro), *Velia* or *Elea*, and *Pæstum* or *Posidonia* (Pesto). The principal inland towns were *Potentia* (Potenza), *Atina*, *Volceium* or *Volcentum* (Buccino), *Grumentum*, *Nerulum*, *Muranum* (Morano), and *Forum Pompilii* (La Polla). The Lucanians became allies of the Romans during the Samnite wars. Yet they joined Pyrrhus when he invaded Italy B.C. 281, and after the battle of Cannæ they revolted to Hannibal. Their defection on both occasions was severely punished. The Lucanians, in the time of Sulla, were raised to the rank of Roman citizens, and after that period gradually sank into obscurity.

LUCANUS, MARCUS ANNÆUS, was born at Corduba (Cordova), in Spain, in A.D. 38. His father was L. Annæus Mella, a brother of the philosopher Seneca, and a man of equestrian rank, who held the lucrative office of *procurator* for the public revenues. The information which we possess regarding the youth of Lucan is by no means trustworthy. The ordinary account of this period of his life is drawn from an old *Vita Lucani*, and sets forth that, conveyed to Rome at the age of eight years, he was carefully educated by the most distinguished philosophers and rhetoricians of the time, under whose instructions he made surprising progress, and gave early proof of being possessed of extraordinary talents; that, having attracted the attention of the Emperor Nero, he was raised to the senate and honoured by a quaestorship while yet a youth; but having afterwards defeated Nero in a poetical contest, was peremptorily commanded by that monarch to refrain from writing poetry in future. As a whole, this narrative is not reliable; yet it is not destitute of authentic elements. The facts seem to be, that roused to jealousy by the extraordinary precocity of the young Spaniard, and by the admiring laudations which his genius called forth, Nero prohibited him from reciting in public. Burning for revenge, the passionate poet joined the celebrated conspiracy of Piso, in which many of the best citizens of Rome were embarked; but having been betrayed, Lucan was induced, through a promise of pardon, to become informer and denounce his associates. He began by naming his innocent mother Atilia as one of his accomplices, and afterwards revealed the rest. (Tacit. *Ann.* xv. 49, &c.) But this traitorous conduct on the part of Lucan did not stand him in good stead. As soon as the leading conspirators were despatched, Nero gave orders that his successful rival should be put to death, and the only favour granted the informer was the liberty of choosing the mode of his death. Summoning all his firmness, and displaying a wild courage equal to the occasion, the unfortunate youth opened his veins in a warm bath, and as his ebbing strength forsook him, began to repeat aloud his own description (*Pharsalia*, iii. 637) of the death-scene of a young warrior who had perished of his wounds. With those lines on his lips, and at the premature age of twenty-seven (A.D. 65), the poet Lucan expired. He left a wife, Polla Argentaria, to mourn his death, who must have been one of the most remarkable women of her time. It is to her that Statius addresses the birthday ode in honour of Lucan, in which he informs us that the earliest production of the deceased poet was a poem on the death of Hector, and the recovery of his body by Priam; the second, on the descent of Orpheus to the infernal regions; the third, on the burning of Rome; the fourth, an address to his wife Polla; and the last, his only extant work, the *Pharsalia*. The latter production is a heroic poem in ten

books, containing a detailed chronological account of the progress of the contest between Cæsar and Pompey from the passage of the Rubicon to the middle of the Alexandrian war. At this point the tenth book stops abruptly; the remaining portion either having been lost or never completed. There is abundant reason for believing that what we now possess of the poem was composed at comparatively distant intervals. The earlier books of the work are characterized by moderation and liberality, with an offensive admixture of flattery to Nero; while as he advances, the spirit of freedom takes fire in him, and he daringly hurls the fiercest invectives at the head of tyranny, which found itself at that time incarnated in the person of the Emperor Nero. Whether this striking alteration of spirit and manner was awakened by the wanton and progressive cruelty of his imperial patron, or whether it arose from the memory of personal wrong and disgrace, it is impossible to determine.

The poetical merits of Lucan have in all ages been fiercely contested; some considering him equal to Virgil, whilst others have placed him in the lowest rank of poets. Both estimates are alike absurd; the one undiscerningly exaggerative of his merits, the other foolishly depreciatory of his powers. As we might be led to expect from these opposing extremes of criticism, Lucan, when impartially studied, reveals singular excellences and as singular defects. He has all the positive elements of a great poet in him,—deep intellectual insight, exalted imagination, burning enthusiasm, noble feeling, fiery energy, and impressive diction; but he wastes his strength by misdirecting it; his power is so exuberant that it overmasters him; he cannot confine it to the path of effective and harmonious activity; it runs wild and irregular, and often ends in extravagance and folly. Time and study would doubtless have done much to emancipate his powers from the crude and depraved taste under which they laboured; but this was denied him.

The best editions of Lucan are those of Oudendorp (1728), Burmann (1740), Bentley (1760), Weber (1821–31), and Weise (1835). The most useful for all practical purposes is the edition of Weber.

The most notable of the numerous translations of the *Pharsalia* are—in English, by Thomas May (1627), who published (1630) a continuation of the poem to the death of Julius Cæsar; by Rowe (1718); and by Riley (1853). Those in French are by Brebeuf (1655), and Marmontel (1766); in German, by Seckendorff (1695), by von Borck (1749), and by Haus (1792); in Italian, by Bocella (1804).

LUCCA, DUCHY OF. See TUSCANY.

LUCCA (anc. *Luca*), a city of Northern Italy, capital of the above duchy, on the left bank of the Serchio, 12 miles from the sea, and 44 miles W. by N. of Florence by railway. It stands on a rich and fruitful plain, is encompassed by a rampart laid out in boulevards, and consists of clean and spacious, but crooked streets. The town is well supplied with water, brought by an aqueduct from the hills to the S. of the town. This great structure, begun in 1815 and completed in 1832, under the superintendence of Nottolini, measures 2 miles in length, and is supported on 459 arches. The appearance of Lucca, when seen from a distance, is striking, from the number of its towers and spires. Among its numerous ecclesiastical edifices, the principal are,—St Martin's Cathedral, and the churches of Saints Fredianus, Michael, and Romanus. The cathedral was founded in 1060 by Bishop Badagio, afterwards Pope Alexander II., and has frequently received repairs and additions. It exhibits a mixture of the Lombard and Gothic styles, and is profusely decorated with every manner of carving, fresco, and sculpture, from the hands of the most famous Italian artists. The church of St Fredianus was erected in the seventh century by King Pertaric of Lombardy, in honour of an Irishman of royal birth named Fredianus, who had left his native country to visit the city of St Peter, and

Lucca.

Luce Bay
||
Lucena.

who was rewarded for his zeal by receiving the episcopal see of Lucca. St Michael's church, founded in 764, and dedicated to the archangel, is built of white marble from the neighbouring quarries, and contains a colossal statue of that personage, besides many excellent carvings and paintings. The church of Romanus, belonging to the eighth century, possesses a celebrated picture of the Madonna by Bartolomeo, and others of less note. The Archbishop of Lucca has many ancient privileges, which have been bestowed on the see at different times by kings and popes. They are now, however, of little value. The palace of the duchy is situate here, and, though unfinished, is an extensive edifice, with a grand marble staircase, and contains a library of 40,000 volumes. One of the most interesting buildings is the poor-house, once the town-hall, built of red brick. It was erected in 1413, and served both for a stronghold and a palace. The most complete of the Roman remains here is the Piazza del Mercata, a ruined amphitheatre of two storeys of arches, and estimated to have held 10,700 spectators. It is now used for the town markets. The manufactures of the town are unimportant, chiefly comprising silk, wool, and paper. Silk, however, was at one time extensively manufactured here, and in the vicinity it was produced for the first time in Italy.

The ancient *Luca* was a town belonging to the district of Etruria, although not possessed by Etruscans; and afterwards was included in Liguria. At the end of the third century B.C., however, it fell into the hands of the Romans, and, according to Velleius, received a Latin colony in 177 B.C. In 49 B.C. it was raised to the rank of a municipal town, and was frequently honoured at that time by the presence of the chief generals and senators of Rome, who formed the plans of their campaigns and political plots here. It did not, however, occupy a conspicuous position till after the fall of the Roman empire. The Goths found it strongly fortified, and a place of some importance. But it was not till the Lombard dynasty had declined that it rose to its greatest height. The twelfth century saw it a free town, governed by its own consuls, until dissensions among the aristocracy again reduced it to the state of a possession held by the most powerful of the nobles. After it had been, however, in the hands of the lords of Pisa for several years, a charter was obtained by the inhabitants from Charles IV. for the sum of 300,000 florins, by which it regained its freedom in 1370. But this freedom was gradually infringed, until the government became a regular despotism; the whole power being in the hands of a few noble families. This state of affairs was rudely changed, however, in 1799, when the French under Serrurier entered the town and seized all the most valuable arms, besides exacting a large sum from the people. Bonaparte, in dividing his empire, bestowed Lucca on his sister Elisa. It is now under the Grand Duke of Tuscany. Pop. 24,894. The famous baths of Lucca are 15 miles N.N.E. of the town.

LUCÉ BAY, an inlet of the Irish Sea, on the S. coast of Scotland, Wigtonshire, so called from the small River Luce which it receives at its head. It divides the county by a broad and deep indentation into two peninsulas, the one terminating in the Mull of Galloway on the W., and the other in Burrow Head on the E. of the bay. It is 19 miles broad at the entrance, 16½ miles long, and about 7 miles broad at the head. Owing to the shifting sands of the bay, it is considered dangerous to navigation.

LUCENA, a town of Spain, province of Cordova, in a beautiful plain near the small River Cascajar, 36 miles S.S.E. from Cordova. The town is composed of 3000 houses, mostly well built and commodious; the streets being also broad and well paved. The Plaza del Coso contains a fine public park planted with trees. The parish church was begun in 1498 on the ruins of a mosque, and finished in 1544. It is built of freestone, and measures about 135 feet

in length by 71 in breadth. On the high altar is a very fine copper bas-relief of the Passion. The town likewise contains 3 hospitals, 3 public schools, and 10 convents, of which the most remarkable, in an architectural point of view, are those of St Augustin and of the Bare-footed Carmelite Nuns. The town enjoys a very salubrious climate, and is well supplied with water, there being 15 public fountains in and near it, besides private wells to almost every house. About 3½ miles E. of the town are the mineral waters of the Horcajo, containing a large proportion of sulphur, and resorted to in cutaneous diseases. The surrounding country is fertile and well watered, producing oil, wine, and cereals, and affording excellent pasturage for horses, cattle, and hogs. The principal branches of industry are the hardware and pottery manufactures. Their lamps are especially celebrated, being made of bronze, copper, &c., variously alloyed, and very beautifully worked; they not only supply Spain and Portugal, but are exported to the contiguous districts of France, to Algiers, and the Havannah. The earthenware manufacture consists chiefly of the large jars with which they supply all Andalusia, and which are used for the storing of oil, wine, and brandy. Some hard white soap is also made. The commerce is confined to the exportation of cereals, oil, vinegar, brandy, lamps, and the above-mentioned jars. There is a yearly fair on the 8th, 9th, and 10th of May, in which all sorts of hardware utensils in tin and copper, earthenware, crystal, and cattle, are exposed for sale.

There are numerous Roman and Gothic remains in Lucena. It was taken from the Moors early in the fourteenth century, and it was in the attempt to recapture it in 1488 that King Boabdil was taken prisoner. Lucena has given birth to various celebrated men, of whom may be mentioned Alvarez de Solomayor, Baraona Solo, author of *Las Lagrimas de Angélica*, and Folch de Cardona, author of a work on military geometry. Pop. 16,652.

LUCERA (the ancient *Lucceria*), a town of Naples, province of Capitanata, on an eminence 12 miles W.N.W. of Foggia. It is surrounded by old walls having five gates, and the houses are generally good, though the streets are narrow, ill paved, and dirty. The cathedral, formerly a Saracenic mosque, has thirteen beautiful pillars of *verd antique*, supposed to have originally belonged to a temple of Apollo. The Bishop's palace is considered the finest edifice in Apulia. The Tribunale is an extensive pile of buildings, including not only the courts of justice for the province, the register office, &c., but also the residences of the president and judges, and the public prisons. Lucera has also a royal college and a fine private museum. About a quarter of a mile from the city, and on the edge of the same eminence, stands the castle of Lucera, a ruined fortress, erected by Frederick II. Three annual fairs are held here; and an active trade is carried on in cattle and cheese. Lucera is said to have been founded by Diomed, and was the capital of Daunia under the Greeks. In the war between Rome and Samnium it had apparently, with the other Apulians, joined the former, and was taken by the Samnites in B.C. 321. The following year it was besieged by the Romans, and after an obstinate resistance, fell into their hands. In B.C. 314 it revolted to the Samnites, but was speedily recovered by the Romans, who put the most of the inhabitants to the sword, and sent thither a body of 2500 colonists to supply their place. It was destroyed in the wars of the seventh century, and lay in ruins till 1239, when the Emperor Frederick II. established here a colony of Silician Saracens, and granted them great privileges. In 1269, however, Charles of Anjou expelled from the Neapolitan dominions such Moors as refused to embrace Christianity, and converted the mosque of Lucera into a church. Numerous antiquities of various periods have been discovered in and about Lucera. Pop. about 12,000.

Lucera.

Lucerne.

LUCERNE, or **LUZERN**, a central canton of Switzerland, having the canton of Aargau on the N., those of Aargau, Zug, and Schwytz on the E., those of Bern and Unterwalden on the S., and that of Bern on the W. It is situate between N. Lat. 46. 47. and 47. 17., and between E. Long. 7. 50. and 8. 29. Its greatest length is 33 miles, its greatest breadth 27 miles, and it has an area of 586 square miles. Generally plain in the N. and irregular in the centre, it is very much broken by ranges of the Bernese Alps in the S., none of which rise, however, above the snow line. Of those ranges the highest is Mount Pilate, reaching in the Tomlishorn, its loftiest peak, an elevation of 7122 feet above sea-level. The only valley of an extensive kind is Entlebuch, 27 miles in length, and inclosed by mountains covered with deep forests, or green pasture land. The Reuss and Little Emmen drain the S. and E. of the canton, and the Wigger, Sur, and Vinon flow all in a northerly direction and join the Aar, an affluent of the Rhine. Bounded partly on the E. by the Lake of Lucerne, and bordering on the lakes of Zug and Schwytz, this canton comprises within itself the small lakes of Sempach, Baldegg, and Mauern. Limestone and sandstone abound in the mountains, and gold has been found in several of the streams. Coal exists to a limited extent in several places, but is not worked. The climate is generally mild, except in the high lands, where snow often lies till June. The soil, though occasionally sandy, is generally fertile, and agriculture is well understood. The cereals raised are in general sufficient for the consumption. The vine is cultivated in the more favoured spots, and chestnuts, figs, and almonds attain maturity on the banks of the Lake of Lucerne. The pastures are very extensive, and of excellent quality, particularly those of the hill-sides which flank the valley of Entlebuch. There is a considerable transit trade; but manufactures, of which the chief are linen weaving and spinning, have made but little progress. The population of the canton in 1850 was 132,843, almost entirely adherents of the Roman Catholic Church, which is the established religion of Lucerne. Of the entire population, 1563 were Calvinists. The government is in the hands of the Great Council, consisting of 100 members, 80 of whom are chosen by the people, and the remaining 20 by the council itself. The Little Council, consisting of 15 members, with its president, or *avoyer*, or *schultheiss*, are elected by the Great Council for three years, and exercise the executive. The canton is divided into 5 bailiwicks, and 74 communes. Lucerne is one of the three *directing* cantons, and occupies the third rank as a member of the Swiss confederation. It contributes annually L.1494, and furnishes a contingent of troops of 3717.

LUCERNE, the chief town of the above canton, lies at the N.W. extremity of the Lake of Lucerne, at the point where the River Reuss, which divides the city, issues forth from the lake. It is exceedingly picturesque, and is walled in towards the land, and surrounded by a series of watch-towers, erected in 1385. Its chief peculiarity, however, is its covered bridges which span the Reuss, and are ingeniously ornamented with curious pictures. The lowest, or Mill Bridge, is hung with paintings, now nearly obliterated, of the "Dance of Death;" the upper, or Kapellbrücke, has 77 pictures suspended from its timbers, illustrative, on the one side, of the pious acts of the patron saints of the place, and, on the other, of memorable incidents in Swiss history. The longest bridge, the Hofbrücke, was removed in 1852, and the only uncovered one is Reussbrücke, which is passable for carriages. The town is clean and well built, and is situate amid exquisitely beautiful scenery, on the margin of the finest of the Swiss lakes, between the magnificent heights of Pilate and Righi. Its principal public buildings are—a cathedral, an Ursuline convent, a town-hall, an arsenal with ancient armour and trophies taken at Sempach, &c., a

large town hospital, a poor-house, an orphan asylum, a jail, and a theatre. It has a lyceum with 14 professors, to which an excellent public school is attached. The educational establishments of Lucerne are highly spoken of for their efficiency. The most interesting monument connected with the place is that in a garden outside the city walls, erected to the Swiss guards, who fell at Paris in 1792, while defending the Tuileries. It was designed by Thorwaldsen, and executed by Ahorn of Constance. "It represents a lion of colossal size, wounded to death, with a spear sticking in his side, yet endeavouring in his last gasp to protect from injury a shield bearing the *fleur-de-lis* of the Bourbons, which he holds in his paws. The figure, hewn out of the living sandstone rock, is 28 feet long and 18 high; and whether as a tribute to fallen valour, or as a work of art of admirable design and no mean execution, it merits the highest praise" (Murray's *Hand-book*). Lucerne is not a place of any considerable manufactures; the chief are cabinet-work, and silk and cotton fabrics. It has some transit trade, however, and it finds a market for its principal fabrics in Italy. There is a railway nearly open to Aarberg on the road to Basle. Pop. 10,068, of whom 300 are Protestants.

LUCERNE, *Lake of*, in the centre of Switzerland, called in German *Vierwaldstättersee*, or "The Lake of the Four Forest Cantons," from its being inclosed by the cantons of Schwytz, Uri, Unterwalden, and Lucerne, is considered to be the grandest in Europe in point of scenery. It is the largest lake in Switzerland, and its surface is about 1400 feet above sea-level. It inclines to a cruciform shape, but is very irregular. Its extreme length is 24½ miles, and its average breadth 3 miles; in depth it varies from 300 to 900 feet. All varieties of scenery are to be met with on its shores, from soft beauty to stern grandeur and sublimity. In the latter respect, the farther end of it, called the Bay of Uri, is unsurpassed. Many of the scenes in Schiller's *Wilhelm Tell* are localized around this lake. The violent storms to which it is exposed render its navigation dangerous. Steamers ply several times a day during summer between Lucerne and Flüelen, and other parts on the shores of the lake.

LUCIA, *St.*, one of the British West India Islands, Windward group, lying about 30 miles S. of Martinique, in N. Lat. 13. 50., W. Long. 60. 58. It is 32 miles in length from N. to S., by 12 in extreme breadth, and has an area of about 235 square miles, or 150,000 acres. It is longitudinally divided by a chain of mountains generally from 1200 to 1800, and in some cases to 2000 feet high, densely clothed with the finest timber. These are of volcanic formation, and assume the most fantastic forms, abounding in deep chasms and pointed eminences. From either side of this chain branches of lesser altitude go off towards the coast, forming plains and valleys of various sizes. At its southern extremity are two mountains of volcanic origin, called the Sugar Loaves, which rise nearly perpendicularly from the sea in the form of parallel cones to the height of about 2700 feet. They are covered with evergreen foliage, and mark the entrance into the deep and beautiful bay of Soufrière. The valleys throughout the island, as well as the plains upon the coast, are fertile, being well watered by numerous streams, and are under good cultivation. The island is divided into two territories,—Basseterre, the low or leeward portion, which is well cultivated and the most populous, though the prevalence of stagnant waters and morasses renders the climate very unhealthy; and Capi-terre, the high or windward territory, which is also very unhealthy, but is becoming less so as the wood on the high lands is being cleared away. The climate is very moist, as the trees on the mountains attract the clouds, and hence render the island subject to frequent and heavy rains for nine or ten months in the year. The quantity of rain that

Lucerne

Total value.....		L.55,836	L.4 6,004	L.6,668	L.3,164

The total value of imports in 1854 (principally articles of British manufacture, flour, dried fish, butter, live stock, lumber, salted meat, olive-oil, wine, rice, and tobacco), was L.96,809; being L.41,996 from United Kingdom, L.27,880 from British colonies, and L.26,433 from foreign states. The net amount of the general revenue in 1854 was L.14,098; being custom duties on imports, L.6482, on tonnage, L.744, assessed and other taxes, L.6872. The net expenditure for that year was L.13,565. The total population in 1854 was 24,123, of whom 430 were male and 517 female whites, 11,081 male and 12,095 female persons of colour. The births, deaths, and marriages were respectively 1069, 2494, and 906. The great number of deaths in that year was principally caused by the cholera; the average of the four previous years being only about 430. This plague had also great influence on the number of marriages, which in that year was more than quadruple the usual annual average. The chief town of the island is Castries, which contains about 3000 persons.

St Lucia was first colonized by English settlers in 1639, but these were soon after driven off by the Caribs. About 1650 the French effected a settlement, and from that time to 1803, when it was finally captured by the English, it belonged alternately to France and England. The government is administered by the commanding officer of the troops, a lieutenant-governor, and an executive council, consisting of the colonial secretary, the attorney-general, and the second military officer. There is also a legislative council, composed of five official and five non-official members, in which the colonial secretary and attorney-general have seats and votes, and of which the commanding officer is president. The laws of St Lucia, except in so far as they have been altered by orders of council, are the laws of France, antecedent to the Code Napoleon.

LUCIAN, Sr, a learned presbyter of Antioch, said to have been born at Samosata, the birthplace of the celebrated satirist of the same name, about the middle of the second century after Christ. Among the old ecclesiastical writers we find him assigned a distinguished place for his

learning and piety. Eusebius (*Hist. Eccles.*, viii. 13) speaks admiringly of his "unblemished character;" and Jerome (*De Viris Illustr.*, cap. lxxvii.) bears a similar testimony. The latter writer refers to him as "laborious in the study of the Scriptures;" so much so, that not only was his revised edition of the *Septuagint* used by the churches from Constantinople to Antioch, but this corrected version of the Old Testament was known by the name of Lucian. Jerome also speaks of him as the author of several epistles and theological tracts; and we find in Socrates (*Hist. Eccles.*, lib. ii., c. 10) an extant confession of faith drawn up by Lucian's hand. He died a martyr in the reign of Diocletian, A.D. 311, and was buried at Helenopolis, in Bithynia.

There is not a little obscurity, and a great deal of consequent dispute, respecting the views held by Lucian on the doctrine of the Trinity. Some have maintained that the absence of any allusion to his opinions on this point by Jerome and Athanasius, and the respect in which he was held by the Trinitarian fathers, afford a sufficient refutation of the charge of heterodoxy brought against the martyr of Antioch. Others, again, on the strength of the testimony of Epiphanius and Philostorgius, who allege that Arianism and Lucianism were all but synonymous, are inclined to hold that the presbyter was a heretic. There are those, again, who maintain a middle course, and favour the opinion that Lucian's views were not quite orthodox, inasmuch as Alexander (in Theodoret, *Hist. Eccles.*, lib. i., c. 4) says that three successive bishops of the Catholic Church excluded him for advocating the doctrines of Paul of Samosata. It is, however, generally believed that he returned to the bosom of the church before his death.

A great deal of confusion respecting the opinions of this eminent scholar and truly pious man has obviously arisen by confounding him with another Lucian, a follower of Marcion, and the author of numerous forgeries, such as the *History of the Nativity of the Virgin Mary*; the *Protangelion, or Gospel of James*; the *Gospel of Nicodemus*, &c. This individual is termed by Epiphanius, Lucian the Elder (*Har.*, xliii., c. 1.) Some call him Lucan, others Lucius and Leucius, &c. That the creed of the latter Lucian was heretical there is no doubt; but how far he has been confounded with his namesake of better reputation it is impossible to determine.

LUCIANISTS, or LUCANISTS, a religious sect (or sects) who derived their name from either of the Lucians just alluded to; or, what is most probable, from both. It is not unlikely that the first who bore the name were the disciples of Lucian the Elder, the Marcionite; and that afterwards it was applied to those who adhered to the tenets of the presbyter of Antioch, which were in all probability slightly tinged with Arianism.

LUCIANUS, a celebrated Greek writer, was born of poor parents at Samosata, the capital of the Syrian province of Commagene. The materials for his biography are very scanty, and are derived chiefly from hints in his own works. He is generally supposed to have lived during the reigns of the Antonines and Commodus; and Reitz, after a minute and able investigation, determines the date of his birth to be about A.D. 120. A talent which he showed in early boyhood for moulding little waxen figures seemed to indicate an adaptation for the trade of a sculptor; and accordingly, at the age of fourteen, he was apprenticed to his maternal uncle, a statuary of some note. Happening however, in his first lesson, to break a marble tablet which he was polishing, he received a severe beating from his uncle. This affront he resented by running away, and persistently refusing to return. He then contrived by some means to devote himself to the study of rhetoric and literature. About the same time, also, he seems to have applied himself to law; for shortly after this period, according to

Lucianists
||
Lucianus.

Lucian.

Suidas, he settled down at Antioch as an advocate. Want of success, however, forced him to become a rhetorician; and making a professional tour, as was customary for those of that calling, he entered Greece, and fixed his abode at Athens. There he remained until his crude knowledge of the Greek language had ripened into a perfect intimacy with the graces of the Attic dialect. There, also, he formed a friendship with the philosopher Demonax, whom he has eulogized so highly. He then passed into Italy, and after staying for some time in Rome, travelled into Gaul. In this latter country he appears to have resided from ten to fifteen years, rapidly acquiring both wealth and fame.

About his fortieth year he left Gaul, but whether he returned through Macedonia to his native city, according to Massieu, or fixed his abode at Athens, according to Wieland, is uncertain. It is agreed, however, that after this period he abandoned the rhetorical profession; and devoting himself to the task of an author, composed the greater part of his works. From his writings we infer that he also travelled much; and while sojourning in Greece, A.D. 165, witnessed the self-sacrifice of the enthusiast Peregrinus at the Olympic games. In his later years he was appointed a procurator in Egypt, probably by the Emperor Commodus. He died at an advanced age. That he was torn to pieces by dogs (as Suidas relates) there is no sufficient ground for believing.

Lucian is most noted as a satirist, and in this capacity he possesses a keen insight into human foibles, great powers of derision, a graceful diction, and a playful and fertile fancy. His great deficiency lies in mistaking both the province and the purpose of satire. Instead of lacerating only the vile and the meretricious, his lash falls indiscriminately upon virtue and vice, upon truth and falsehood. Instead of probing the wound to heal it, he tortures it merely to see his victim writhe. Thus he attacks Christianity and natural religion—not with the view of substituting other systems in their place, but simply to hold them up to derision. If his sneers ever put vice and folly to the blush, the result arose more from accident than from the design of the writer. Accordingly Lucian's satire, instead of that moral tone so often effectual in elevating this species of writing into the atmosphere of poetry, not unfrequently shows a coarseness both in taste and sentiment.

The *Dialogues* of Lucian are at once the best and most bulky part of his works. Of these, the most notable perhaps are the *Dialogues of the Dead*, which, traversing the entire circle of human weakness and error, expose the hollowness of fame, wealth, and beauty, the absurd tenets of the vulgar, and the endless jargon of the sages. In his *Sale of the Lives*, the auction of the different philosophers affords him a good opportunity for facetiously describing the market value of the several philosophical systems. The same strain of ridicule is pursued in his *Symposium*, in which the various sages who had been invited to a wedding banquet, begin a contest with grave words, but end it with hard blows, and amid general uproar. A more legitimate satire is *Jupiter Convicted*, in which the king of the gods is proved before his own face to be utterly powerless, and the mere puppet of destiny. This attack upon the popular mythology Lucian followed up by aiming, in his *Jupiter Tragedus*, at the very existence of the gods. In one of his best pieces,—*The Dream of Micellus or the Cock*,—a cobbler, Micellus, discovers Pythagoras under the semblance of a cock, and on plucking two feathers from the tail of the philosopher, becomes invisible, and is thus enabled to pass through the mansions of the rich, and view their vice and miseries. *Timon, or the Misanthrope*, is written in his best manner.

Lucian's romances include *Lucius, or the Ass*, and *The True History*. The former is supposed by Photius to be founded on a tale by Lucius of Patrae. The

latter was intended as a caricature of all extravagant narratives, including the tales of Ctesias and Iambulus, and the *Odyssey* of Homer; and may be considered as the prototype of Swift's *Gulliver*. Among Lucian's miscellaneous works, the ablest is that entitled *How to write History*. The best edition of Lucian is that of Hemsterhuis and Reitz, 3 vols. 4to, Amsterdam, 1743, supplemented by another volume entitled *Lericon Lucianum*, by K. K. Reitz, Utrecht, 1746. There are other editions by the Bipont Society, 10 vols. 8vo, 1789–93; by Lehman, Leipsic, 9 vols. 8vo, 1821–31; and by Dindorf, 8vo, Paris, 1840. Lucian has been translated into German by Wieland, 6 vols., Leipsic, 1788–9; into French by De Ballu, 6 vols. 8vo, Paris, 1788; and into English by Dr Franklin, 2 vols. 4to, London, 1780, and 4 vols. 8vo, London, 1781–82.

LUCIFER, Bishop of Cagliari, and founder of the Luciferians, first appears in history as a zealous antagonist of Arianism. In 354 he was deputed by Liberius, Bishop of Rome, to advocate the cause of Athanasius at the council of Milan, an office which he discharged with such persistent boldness, that he and his fellow-legate, Eusebius of Vercelli, were banished by the Arian emperor, Constantine. After his place of exile had been changed several times without producing any corresponding alleviation of his sufferings, he settled down at Eleutheropolis, in Syria, and there wrote his chief work, *Ad Constantium Augustum pro Sancto Athanasio, Libri II.* The unbridled invective and outrageous vehemence of this book were not more remarkable than the boldness of Lucifer in avowing the authorship, when afterwards interrogated by the emperor. Soon after this Lucifer seems to have been removed to Egypt. On his release from exile at the death of Constantius, the council of Alexandria commissioned him, along with Eusebius, to heal the division in the church of Antioch that had arisen from the supposed Arianism of Meletius, bishop of that see. Instead, however, of fulfilling his duty, he widened the schism by attempting to place Paulinus in the bishopric, and thus laid himself open to a reproof from Eusebius and his other long-trying friends. Chafing under the rebuke of all sections of the church, and displeased with the decree of the Alexandrian council for readmitting into ecclesiastical communion those bishops who had temporized with the Arians, Lucifer withdrew, in 363, to his native island of Sardinia, and there founded the small sect known by his name. He died about A.D. 370. Besides the book mentioned above, his other works are—*Epistola ad Eusebium*; *De non Conveniendo cum Hæreticis*; *De Regibus Apostolicis*; *De non Parcendo in Deum delinquentibus*; *Moriendum pro Filio Dei*; *Epistola ad Florentium Magistrum Officiorum*; and *Epistola ad Catholicos*. The last is not extant. Deficient in method and argument, and pervaded by an acrimonious and intolerant spirit, these works merit preservation solely in virtue of the many scriptural quotations which they contain. They were first collected and published by John du Tillet, Bishop of Meaux, Paris, 8vo, 1563, and afterwards reprinted in the *Magna Bibliotheca Patrum*, 1618, and in the *Bibliotheca Patrum* of Galland, folio, Venice, 1770. The best edition is that of the Brothers Coleti, folio, Venice, 1778.

The *Luciferians* (who did not long outlive their founder) disowned all who had ever been tainted with Arianism and all who countenanced those who had been reclaimed from that creed. They renounced, accordingly, all the Christian world beyond their own confined pale. Augustine supposes that they also held that the soul, like the carnal nature, was transmitted from parent to child.

LUCILIUS, CAIUS, a Roman knight, who is generally considered the inventor of satirical composition,—at least of that new form adopted by Horace, Persius, and Juvenal. Of his personal history we can collect only a few facts. He was born 148 B.C. at Suessa (*Sessa*), a city of the Aurunci,

Lucifer

|| Lucilius.

Lucken-
walde
||
Lücke.

in Latium (Juv. i. 20). He attended Scipio Africanus in the war against Numantia, B.C. 134, at an age when he could scarcely be expected to serve in arms, and at that time he acquired the friendship of the younger Scipio, and of Lælius (Vell. Pat. ii. 9). Lucilius died at Naples in 103 B.C. His works consist of thirty satires, epodes, hymns, a comedy entitled *Nummularius*, and a *Life of Scipio the Elder*. Of his Satires, upwards of 800 fragments remain, the longest of which, however, amounts only to thirteen verses. Yet even in these stray remnants one can detect traces of that pungent wit and merciless rebuke which are mentioned by Juvenal (i. 165) as causing the victims of Lucilius to tremble. His blows were openly aimed at vice and folly in whatever rank or under whatever dignity they appeared. More marked, however, by strength than by purity and finish, his poetry is compared by Horace to a river bringing down particles of gold and mud mingled together; a criticism which is probably just, in spite of the protest made against it by Quintilian in his *Institutions*. Of the thirty satires of Lucilius, the first twenty and the thirtieth seem to have been written in hexameters, and to have been the first specimens of that measure among the Romans. In the rest, the iambus and trochæus appear to have been used. The fragments of Lucilius have been published by Dousa, with learned notes, Leyden, 1597, Amsterdam, 1661; and reprinted by Volpi, Padua, 1735. They are included in Maittaire's *Corpus Poetarum Latinorum*, London, 1713, and are appended to the *Persius* of Achaintre, 8vo, Paris, 1811.

LUCKENWALDE, a town of Prussia, in the province of Brandenburg, situate on the River Nuthe, on the Berlin and Anhalt Railway, 31 miles S. of the former city. It has woollen and linen factories, and manufactures scythes, leather, paper, and spirits. It has a court of justice, and a parish and burgh school. Pop. 7500.

LÜCKE, GOTTFRIED CHRISTIAN FRIEDRICH, one of the most learned theologians of Germany, was born at Egehn, in the duchy of Magdeburg, 23d August 1792. He received his early education at the gymnasium of his native city, and after the Easter of 1810 studied theology for two years at Halle, under Knapp and Gesenius. From Halle he removed to Göttingen, where he continued his studies under Planck; and here he became first known from his prize essay on the church of the apostolic age (*De Ecclesia Apostolica*, Gött. 1813). The publication of this little work procured him at once the office of repetent in the theological faculty. It also drew him into close literary friendship with Bunsen, Ernest Schulze, Brandis, Lachmann, and others, who were students and aspirants for literary distinction about the same time. Lücke was soon afterwards drawn by the personal influence of Schleiermacher to Berlin, where he passed as licentiate of theology. In 1817 he published at Göttingen his *Grundriss der Neutestamentlichen Hermeneutik*, a youthful but brilliant attempt to mark out the limits of his favourite study, that which he delighted to designate as Christian philology. In the spring of 1818 he was appointed extraordinary professor of theology at Bonn; and in the following autumn he received promotion to an ordinary professorship. Here he devoted himself with the greatest enthusiasm to the study of exegesis and of church history. Besides contributing to the *Theologische Zeitschrift* and the *Christliche Zeitschrift* of Bonn, he about this time began his *Commentary on the Writings of John* (4 vols., Bonn, 1820-32); and to the same period belongs his *Trilogie* with Nitzsch and Sack, and his celebrated letter to Delbrück (Bonn, 1827) on the relation of Scripture to the rule of faith. In 1827 Lücke succeeded Staudlin as professor of systematic theology at Göttingen, where he continued to reside till his death in Feb. 1855. Lücke contributed valuable papers to the *Studien und Kritiken*. To him especially we owe many biographical notices of the great men with whom he had

been closely associated in study, and whose names form landmarks in the progress of theological literature. The best known of these biographical sketches are those of Planck (1835), of Schleiermacher (1834), and of De Wette (1850). Towards the close of his life, he contributed to the *Deutsche Zeitschrift für Christliche Wissenschaft und Christliches Leben*; and during the conflict with Strauss, he wrote anonymously a little tract entitled *Strauss und die Züricher Kirche* (1839).

It is undoubtedly as a commentator that Lücke deserves chiefly to be remembered. In common with the whole school of Schleiermacher, to which he belonged, he gave a marked preference in study to the writings of the apostle John, and these he has illustrated with a freshness and vigour at that time unequalled in the whole library of comment. Beyond all his compeers he is the artist of exposition; and in the interest with which he handles dull details of criticism to bring out the hidden beauties of Scripture, he is inferior only to Bengel and Stier. He is, however, too often led astray by his preferences for the fourth Gospel, and his labours have lost much of their interest since the attack of Strauss has given a wider range to modern German criticism, and has shown the danger of a false preference in a matter so vital to the interests of Christendom. In an honest recoil from dogmatism, which he hated instinctively and combated fiercely, Lücke has often unfortunately stopped short in the scrutiny of notorious difficulties, and left them unsolved, when another step in the analysis would have sufficed to clear away every trace of doubt. The greatest blot on his pages is his ascription of the Apocalypse to an unknown author, whom he supposed to have flourished in the reign of Nero; but his greatest merit remains, of having been one of the foremost and the most powerful to break up the dominion of rationalistic criticism, and to clear the way for a philology more thoroughly Christian even than his own.

LUCKNOW, a city of Hindustan, and the capital of the province of Oude, situate on the S. bank of the River Goomty, which is navigable for boats of a common size at all seasons of the year, and falls into the Ganges between Benares and Gazypoor. At the north-western extremity of the city is a bridge, a very noble Gothic edifice of stone; another to the S.E. is formed of boats. A complete iron bridge was, in 1816, sent out from England in sections, but the death of the ruling prince having stayed the progress of the undertaking, it long remained suspended in consequence of the reluctance of the new sovereign to complete a project commenced by a predecessor. At length, after the lapse of about thirty years, the bridge was erected, and now forms a conspicuous ornament of the city. The streets where the lower classes reside consist of mean houses built of clay, "with the filthiest lanes between them," says Bishop Heber, "that I ever went through, and so narrow that we were obliged to reduce our front, and even a single elephant did not pass very easily." "A swarm of beggars," he continues, in the lively description which he gives of the aspect of the town and its population, "occupied every angle, and the steps of every door, and all, or nearly all, the remaining population were, to my surprise, as much loaded with arms as the inhabitants of the country,—a circumstance which told ill for the police of the town, but added considerably to its picturesque effect. Grave men in palanquins, counting their beads, and looking like moulahs, had all two or three sword or buckler lacqueys attending on them. People of more consequence, on their elephants, had each a retinue of shield, spear, and gun, little inferior to that by which we were surrounded; and even the lounging people of the lower ranks in the streets and shop-doors, had their shields over their shoulders, and their swords carried in one hand." Lucknow is a very ancient city. It was the residence of the early governors or nabobs

Luckput
Bunder
||
Luçon.

of Oude, but was abandoned by Shujah and Dowleh after the battle of Buxar; on his death in 1774, however, his successor returned to it, and the bankers and men of property having accompanied the court, Lucknow became one of the largest and richest towns in Hindustan. At the present time the city is represented as displaying a varied, lively, and even brilliant prospect, when viewed from a position elevated above the general height of the buildings. In advancing into the town from the outskirts above described, the buildings begin to improve, though the streets continue to be equally narrow. Some of the streets are, however, more spacious; and one in particular is mentioned as being both wide and handsome. It is called Chinka Bazar, or Chinese Market, and has at each end a handsome gateway. Heber describes it as wider than the High Street at Oxford, but having some distant resemblance to it in the colour of its buildings and Gothic style of the greater part of them. The bishop adds that Lucknow appeared to have more resemblance to some of the smaller European capitals, such as Dresden, than any other town which he had seen in India. There are several palaces in Lucknow belonging to the late king, but none of them are very striking buildings. There is one close to the British residency, which is merely a cluster of mean houses, with some morsels of showy architecture intermingled like the offices of a college. There are many stately khans, and some handsome mosques and pagodas, scattered in different corners of the most wretched alleys. The most striking buildings in Lucknow are the tombs of Nawab Saadut Ali and other princes of the dynasty, and the imambarah. The latter building consists of two courts, rising with a steep ascent one above another. It contains, besides a splendid mosque, a college for instruction in Mussulman law; apartments for the religious establishment maintained here; and a noble gallery, in the midst of which, under a brilliant tabernacle of silver, cut glass, and precious stones, lie buried the remains of its founder, Asuph ad Dowlah. The whole is in a very noble style of eastern Gothic, and is distinguished by richness and variety, as well as by the just proportions and general good taste of its principal features. Amongst the curiosities in the neighbourhood is Constantia, the residence of the late General Martin, who, from being a common soldier, rose to a high rank in the company's army. His house is a large and whimsical building, and the grounds are laid out in the worst possible taste, displaying in the outline and arrangements the eccentric genius of the contriver. His body is deposited in a sarcophagus in one of the lower apartments. A large share of his vast wealth was devoted to charitable purposes; and a college called after the founder "La Martiniere," preserves his memory in the city where his fortune was accumulated and his eccentricities indulged. The population of Lucknow is estimated at 300,000; and Bishop Heber is of opinion that it is sufficiently crowded to contain that number. The city is 650 miles travelling distance from Calcutta, from Delhi 280, from Agra 202, and from Benares 189 miles. E. Long. 81., N. Lat. 26. 51. The long-continued misgovernment of the territory, of which this place is the capital, compelled the British government at length to assume the administration of public affairs. The king refusing to accede to the proposed conditions, was deposed, and a liberal allowance assigned for his maintenance. (See OUDE.) (E. T.)

LUCKPUT BUNDER, a town of Hindustan, province of Cutch, situate about 30 miles up the Koree River or Salt Creek, which communicates with the Great Western Runn, and is only navigable for small vessels. It is defended by a fort, which is situate on the brow of a hill. It is not estimated to contain more than 2000 inhabitants, 500 of whom are Sepoys; and it is at present a place of little trade. Lat. 23. 50., Long. 68. 48.

LUCON (ancient *Lucio*), a town of France in the de-

partment of Vendée, situate on the edge of a marshy plain, at the extremity of a canal of the same name, 10 miles in length, which traverses the marshes of Fraissy and St Michel-en-l'Herm, and joins the sea at the little Bay of Aiguillon. It is large, with dirty tortuous streets, and very unhealthy. It has a good trade in grain and cattle. The only building worthy of note is its cathedral, of Gothic architecture. It possesses a communal college, and is the seat of a bishop. It was to this see the celebrated Cardinal Richelieu was elevated at the age of twenty-two. The Republicans sustained a defeat under the walls of Luçon in 1793; and the insurgent Vendéans besieged the place some months afterwards, but without success.

LUCRETIA, the famous Roman matron, wife of Collatinus, and the cause of the revolution in Rome by which the constitution of the state was changed from a monarchy to a republic. This lady being ravished by Sextus, the eldest son of Tarquin, King of Rome, stabbed herself, in the year 509 B.C. The bloody poniard, with her dead body exposed to the senate, was the signal of Roman liberty; the expulsion of the Tarquins, and the abolition of the regal dignity, were instantly resolved on, and carried into execution.

LUCRETIUS, a celebrated Roman poet and philosopher. Of the life of Titus Lucretius Carus (as his full name is written) very little is known. As he styles the Latin language his mother tongue, we infer that he was a Roman, or at least an Italian. According to the Eusebian chronicle (almost the sole authority on the subject), he was born in 95 B.C., and died by his own hand in 52 B.C.; and his poem *De Rerum Natura*, which had been written during the intervals of a frenzy caused by a love-potion, was afterwards edited by Cicero. The account of his madness is rendered doubtful by the internal evidence of his work. In no poem do we see more distinct traces of the various human faculties acting harmoniously under the sovereignty of reason. There is no distinct evidence of Cicero's having edited the poem of Lucretius. The story about his suicide is much more probable. His opinions touching the mortality of the soul, his fearless Roman spirit, and his stern decision of character, might possibly enough urge him to adopt this mode of ridding himself of any dire calamity.

His poem *De Rerum Natura* consists of six books, and is dedicated to his friend, C. Memmius Gemellus, who was prætor in 58 B.C. Lucretius evidently received the first obscure hints of his system from Empedocles; but raised it into symmetry and consistence by aid of the atomic philosophy of Epicurus. Starting from the axiom that *nothing can be produced from nothing*, and holding that the laws of nature, and not the gods, are the creative principles of the universe, he attempts to prove that all things are formed by the combinations of indivisible and eternal atoms. After describing the different spontaneous motions by which these primary particles come to be combined into sensible qualities, Lucretius passes on in the third book to trace the soul of man to the same origin. From this conclusion, he advances easily to the doctrine that the soul is material, and must therefore perish when life, the band that unites it with the body, is snapt asunder. In the fourth book he expounds his theory of the senses, of sleep, and of dreams. The fifth book is occupied with disquisitions on the origin of the world, on the movements of the stars, on the laws that regulate the seasons, and the interchange of day and night, and on the gradual development of civilization. In the sixth book he endeavours to account for physical phenomena, such as thunder, rain, earthquakes, volcanoes, and pestilences. The abruptness of the conclusion, a feature not seen in the rest of the work, renders it very probable that Lucretius left his poem unfinished.

As the body of the system is Epicurean, so also is the

Lucretia
||
Lucretius.

Lucullus. spirit which animates it. A philosophy that recognises natural laws as the source of creation, is of necessity pervaded by a deep reverence for nature. Standing, therefore, in the same relations to Lucretius as the muse and the gods did to Homer and the other ancient poets, nature is invoked at the very commencement of the poem, and the manifold manifestations of her power furnish the themes of the poet's noblest strains. Her ever-varying moods, too mysterious to require poetical idealizing, are depicted with minute faithfulness, and are lingered over with devotion. The poet beholds her sunshine, beauty, and beneficence, with gladness; her tempests, famines, earthquakes, and pestilences, with sublime wonder. Mankind, as the noblest part of nature, attract the special interest of Lucretius. Their joys and sorrows are the themes of some of the most exquisite episodes in his poem; and the professed object of his philosophy is to release them from superstitious fears. Accordingly, he tells them that there is no after-time of retribution; and that the gods, whose anger they fear, dwell too far above this sphere, and are too listlessly happy, to regard the sins and exact the services of the human race. He recommends, as the aim of life, that quiet of the soul which is attained by the suppression of all fears and vicious passions. This lesson is enforced by the very shortness of the time in which the end must be gained.

In Lucretius we see the harmonious working of the two great powers of imagination and reason—the former describing conclusions while yet at a distance, and the latter searching for a path by which they may safely be reached. Often misled by the careless induction peculiar to antiquity, his reasonings are nevertheless founded on a minute and extensive observation. The most striking feature, however, in the entire poem, is the vigour with which the closest arguments and the subtlest abstractions find poetical expression in a language formerly rude and undeveloped. Scarcely less wonderful is the full melody of his hexameters. The fervid genius of Lucretius acted with a refining vehemence upon the rugged ore of his native tongue, purged it of its dross, and fused it into the golden speech of poetry. Many of his epithets are terse and felicitous, and his images possess that suggestive power which it is the sole prerogative of poetic genius to originate. He possesses, also, the happy art of relieving the sterner and darker pictures of his poem by sweet glimpses of sea-shore and rural solitude.

The best editions of Lucretius are those of Lambinus, Paris, 1564–70; Creech, Oxford, 1695; Wakefield, London, 1796–97; Eichstädt, Leipsic, 1801; and Forbiger, Leipsic, 1828. The latest English translation is that of the Rev. John Selby Watson, published along with a metrical version by Mason Good, London, 1852. See “Lucretius and the Poetic Characteristics of his Age,” by W. Y. Sellar, in *Oxford Essays*, London, 1855.

LUCULLUS, **LUCIUS LICINIUS**, the conqueror of Mithridates, was born probably about 109 B.C. At an early age he distinguished himself so much in the social war, that Sulla gave him the command of a fleet during the first war with Mithridates, and appointed him quaestor of Asia. After discharging this office with great prudence, he returned to Rome in 80 B.C., to fill the curule ædileship, and in the following year he was appointed praetor. No sooner had he been elected consul in 74 B.C., than the second Mithridatic war broke out, and Lucullus hastened into Asia to attack the enemy. His first exploit was the relieving of his colleague, Cotta, who, after suffering defeat both by land and sea, had been shut up in Chalcedon. Attacking the enemy successively at Rhyndacus, the *Æsepus*, and the Granicus, Lucullus in a short time annihilated the land forces of Mithridates. He mustered a fleet with equal celerity, and routed the squadron of the king near the island of Lemnos. Mithridates had, meanwhile, retreated

into his native kingdom, and thither Lucullus now marched. After baffling the pursuit of the Romans for some time, the king was forced, in 72 B.C., to flee to his son-in-law, Tigranes, Prince of Armenia. To this country accordingly, the war was transferred in 69 B.C., and the defeat of the Armenian forces before the walls of their capital, Tigranocerta, was followed soon after by the fall and pillaging of that city. In 68 B.C., Mithridates and Tigranes had consolidated their shattered armies, and met Lucullus at the River Arsanias, but were again defeated and forced to flee ignominiously. Other successes would have followed, had not a spirit of disaffection in the minds of the soldiers, that was due partly to the reserved disposition of Lucullus, and partly to the machinations of his enemies at Rome, now broken out into open mutiny. After struggling with it ineffectually, and seeing Mithridates recover Pontus and Cappadocia, Lucullus, in 66 B.C., was superseded in the command by his old rival Pompey. On returning to Rome, his well-earned triumph was delayed for three years, through the intrigues of his enemies. He then passed into private life to enjoy the immense wealth he had amassed in the East, and he soon became as noted for his luxurious indolence as he had been for his military activity. He laid out extensive gardens in the suburbs of Rome, and built two magnificent villas, the one near Neapolis, and the other at Tusculum. A student and a lover of the fine arts from his earliest years, he now passed much of his time in collecting an extensive library, in decorating his mansions with costly paintings and statues, and in conversing with the learned men whom he loved to gather round him. Cicero was his intimate friend, and in the *Academics* praises his learning very highly. Shortly before his death, which happened at some time previous to 56 B.C., Lucullus is said to have fallen into a state of dotage. He was the first to introduce cherries into Europe.

LUCULLUS, *Marcus Licinius*, a younger brother of the preceding, was also called M. Terentius Varro Lucullus, on account of his adoption by M. Terentius Varro. Under Sulla he held the office of quaestor, and afterwards of a lieutenant. In 77 B.C. he was appointed praetor, and succeeding his brother as consul in 73 B.C., obtained Macedonia for a province, and there waged a successful war with the Bessi, the Dardanians, and the Greek cities on the Euxine. His exploits were rewarded by a triumph in 71 B.C. In 67 B.C. he was one of the legates appointed to settle the affairs of Pontus, and appears in history as one of the leaders of the aristocratic party in 65 B.C. He died at some period before 49 B.C. M. Lucullus is characterized by Cicero as one of the “lights and ornaments of the republic.”

LUDEHAUNAH. See **LOODIANA**.

LUDLOW, **EDMUND**, son of Sir Henry Ludlow, was born at Maiden-Bradley, in Wilts, in 1620, and educated at Trinity College, Oxford. His father being opposed to the king's interest, Mr Ludlow joined the same party, and was present at the battle of Edgehill, 1642, as a volunteer, under the Earl of Essex. Upon the death of his father, he was chosen knight of the shire for Wilts, and obtained the command of a regiment of horse for the defence of that county. He was one of the judges of Charles I., and after his death was sent by the parliament into Ireland, 1650, in quality of lieutenant-general of the horse; an employment which he discharged with diligence and success until the death of the lord-deputy, Ireton, when he acted for some time as general, though without that title. Cromwell, who knew him to be sincerely in the interest of the commonwealth, had nevertheless not sufficient confidence in Ludlow to warrant him in elevating him formally to the generalship. When Cromwell assumed the protectorate, Ludlow gave in his “solid” protest against that step, and he even refused, on leaving Ireland, to yield the Protector

Lucullus
||
Ludlow.

Ludlow
||
Ludolphus.

an unqualified submission. He sought retirement in Essex until Oliver's death, when he used his efforts to restore the commonwealth; but Charles II. being recalled, he thought proper to conceal himself, and escaped into Switzerland, where he settled in 1660, in the neighbourhood of the town of Vevay, where more than one English refugee have found a home and a grave. After the Revolution he came over to England, 1689; but having appeared publicly in London, it gave great offence, and an address was presented by Sir Edward Seymour to King William III., praying for a proclamation in order to apprehend Colonel Ludlow, attainted for the murder of King Charles I. Upon this he returned to Switzerland, where he died in 1693, aged seventy-three years. Over the doorway of his house he placed the inscription, *Omne solum forti patria*. His grave is still shown at Vevay. His *Memoirs* were written during his retirement in Switzerland, and published at Vevay, in two volumes, in 1698, which were followed by a third volume during the next year.

LUDLOW, a parliamentary and municipal borough and market-town of England, Shropshire, on the left bank of the Teme at its junction with the Corve, 36 miles W. by S. of Birmingham. It stands on a gentle acclivity, and is overlooked by an old castle, situate on a wooded eminence. The streets are spacious, the houses well built, and the town is well supplied with water. It contains a parish church, a cruciform edifice in the perpendicular style, erected in the beginning of the fourteenth century; chapels belonging to the various religious denominations; and several schools, one of which, the Free Grammar School, was founded by Edward VI. Besides these, there are a mechanics' institute, and a natural history society with a good museum. On a bold rock overhanging the river is the old and now ruined fortress of Ludlow, erected in the twelfth century by the lords of Montgomery, for the defence of the English border against the Welsh inroads. It was afterwards frequently honoured by the residence of royalty. The Duke of York held it for some time during the wars of the Roses, until he was forced to give it up in 1459 by the advance of the king's forces against him. Henry VII. made it his residence, and his son held court within its walls. In later times, Prince Charles, afterward Charles I., visited it; and in 1634 Milton's *Comus* was performed for the first time in its hall.

Ludlow is governed by a mayor, 4 aldermen, and 12 councillors, and returns 2 members to parliament. Markets on Monday, Wednesday, and Saturday. Pop. (1851), parliamentary borough, 5376; municipal borough, 4691.

LUDOLPHUS, JOH (or *Leutholf*), a learned writer, was born at Erfurt, in Thuringia, on the 15th June 1624, and received a university education at Leyden, where he devoted his study chiefly to law and oriental languages. He held successively the position of tutor to the sons of the Swedish ambassador at Paris, and to the children of the Duke of Saxe-Gotha at the court of that prince. By the aid of a native of Abyssinia, whom he met at Rome in 1649, while on a literary commission, he mastered the Ethiopic language,—an achievement never before accomplished by any European,—and published in 1661, at London, a dictionary and grammar of that tongue, which he afterwards brought out in a more improved form at Frankfort in 1698 and 1702. His knowledge of languages was exceedingly extensive; and he spared no labour by travel, study, and converse with learned men, to make himself what he ultimately became—one of the most distinguished orientalists of his age. He died at Frankfort-on-Main, on the 8th April 1704.

In addition to those already alluded to, the most important of Ludolph's works are:—*Grammatica Lingua Amharicæ, quæ vernacula est Habessinorum; adjectum est Lexicon Amharico-Lat.*, 2 vols. folio, Franc. 1698; *His-*

Ludwiga-
burg
||
Lugdunum.

toria Ethiopica, sive descriptio regni Habessinorum, folio, Franc. 1681; *Ad suum Historiam Ethiopicam Commentarius*, 1691; *Relatio Nova de hodierno Habessinæ statu ex India nuper allata*, 1693; *Appendix continens Dissertationem de Locustis*, 1694; *A New History of Ethiopia*, &c. (an English edition of his *Historia Ethiopica*), folio, London, 1684.

LUDWIGSBURG, a town of Würtemberg, circle of Neckar, about a mile W. of the river of that name, and 8 miles N. of Stuttgart. Ludwigsburg has the character of being one of the handsomest and best laid out towns in Germany. The streets are mostly long, wide, and regular, and are generally lined with rows of trees. This town dates only from the beginning of the last century, at which time the reigning duke, Eberhard Ludwig, had a hunting-seat here. A palace was soon after erected, and from 1727 to 1733 Ludwigsburg was the chief residence of the court. The palace, which is now deserted, is one of the largest in Germany. It has a gallery of old German, Dutch, and Flemish pictures, of no great value. The palace gardens, once famous over Germany, are now falling into disorder from neglect. Ludwigsburg has a military college, lyceum, arsenal, orphan asylum, theatre, &c.; also a cannon foundry, and manufactures of woollen cloth, linen, calico, jewellery, leather, and earthenware. In the neighbourhood are the two royal chateaux of Mouriépos and La Favorite. Pop. about 8000.

LUDWIGSLUST, a market-town of North Germany, grand duchy of Mecklenburg-Schwerin, on the Hamburg and Berlin Railway, 20 miles S. of Schwerin. The principal building is the summer palace of the grand duke, having a gallery of about 200 pictures, some of them good specimens of the Dutch school, and a collection of Slavonic antiquities found chiefly in the duchy. Attached to the palace are a spacious park and garden. The Russian chapel contains the tomb of the Archduchess Helena, Grand Duchess of Russia, who died in 1803. Pop. 5500.

LUGANO, a thriving town of Switzerland, canton of Tessin, on the northern shore of Lugano Lake, 16 miles S. by W. of Bellinzona. It is beautifully situate on the margin of the lake, and is surrounded by a most luxurious country, but the town itself is not well built, and the streets are dirty. The chief public buildings are,—a college, a small theatre, an hospital, founded in the twelfth century, and several schools and churches. Of the latter, the principal are those of San Lorenzo, situate on an eminence, and Santa Maria degli Angeli, founded in 1499, and containing some excellent paintings. Silk grown in the canton is manufactured here extensively, besides tobacco, paper, leather, and copper; and a brisk transport trade is carried on with Italy by means of the lake. Lugano is also the seat of a considerable printing and publishing trade. Pop. 4500.

LUGANO, *Lake of* (*Lacus Ceresius*), a long, narrow sheet of water, lying between Lakes Como and Maggiore, and situate mostly within the Swiss canton of Tessin. It is of a very irregular form, the N.E. portion of it projecting into Lombardy, while from its other extremity a long narrow arm extends northward, forming the boundary between Switzerland and Lombardy. The length of the lake from N.E. to S.W. is about 16 miles, and its average breadth does not exceed 2 miles. It receives numerous tributaries, and discharges its surplus waters by means of the Tresa into Lake Maggiore. The scenery is very striking, the lake being almost surrounded by lofty mountains, overhanging woods, and bold, abrupt precipices. In some parts, however, its banks slope gently to the water's edge, and are covered with villages, gardens, vineyards, &c. Abundance of excellent fish is caught here.

LUGDUNUM (modern *Lyons*), a Roman settlement of Gallia, the capital of the Segusiani, situate at the confluence of the Rhodanus (*Rhone*) and the Arar (*Saône*), is said to

Lugdunum have been colonized, in 43 B.C., by refugees from Vienna (*Vienne*). Its position at the junction of several Roman roads soon rendered it the seat of a thriving commerce, so that in the time of Strabo it was one of the most populous towns in Gaul. It was burnt in the time of Seneca, but was soon afterwards rebuilt by Nero. In 197 A.D. it was burnt again by the soldiers of Septimius Severus. Lugdunum contained the famous *Ara Augusti*, erected in 12 B.C. or 10 B.C., by the sixty Gallic States in honour of Augustus. In the reign of Marcus Aurelius this town was the scene of a fierce persecution of the Christians.

LUGDUNUM BATAVORUM, in *Ancient Geography*, a town of the Batavi, in Gallia Belgica; now *Leyden*, in Holland.

LUGO, a town of Italy, Papal States, delegation of Ferrara, and 32 miles S.S.E. of the town of that name. It is situate in a plain about midway between the Senio and Santerno rivers, and is supposed to occupy the site of *Lucus Diana*. It carries on an important trade, and has a large annual fair, which lasts from the 1st to the 19th of September. Lugo was sacked and nearly destroyed by the French in 1796. Pop. 9500.

LUGO, a province of Spain, one of the four into which the ancient kingdom of Galicia has been divided, is situate on the coast of the Atlantic, between N. Lat. 42. 22. and 43. 47.; W. Long. 6. 52. and 8. 4.; bounded E. by the provinces of Oviedo and Leon, W. by those of Pontevedra and Coruña, S. by the province of Orense, and N. by the sea. It has a coast of about 40 miles in length from Ribadeo to Cape Bares, extremely rugged, and inaccessible to all but fishing boats. Such ports as there are—Ribadeo, Rilo, Foz, San Ciprian—are of small capacity and depth, and obstructed by bars; while the mountains close behind are barren and almost impassable. The province is generally mountainous, especially in the N. and E. The highest summit, that called Rico de Peña Rubia, has an elevation of 6088 feet above sea-level. Inclosed are a great number of fertile valleys; in that of Miranda, on the left bank of the Eo, are cultivated not only the cereals, but also fruit and wine. The valleys of the Oro and Vivera, that called the Riberas del Sor, and that of Monforte, are also very productive. The *partido* of Lugo, the capital, comprehends the delicious valleys of the River Miño and its affluents. The River Miño is the most considerable in the province. It has its rise in the Sierra de Meira, passes the town of Lugo after receiving various smaller streams, and joins the Sil at Los Peares. Sufficient advantage, however, is not taken of the abundant supply of water, and agriculture is in rather a backward state. This is also partly owing to the paucity and badness of the roads, which in this province, as throughout Galicia, are deplorably defective. The productions of the soil are rye, maize, wheat, legumes of various kinds, flax, hemp, and some silk. There is abundance of wood both for building purposes and for fuel. The cultivation of hemp has been almost entirely destroyed by the absurd restrictions of the government. In Caurel and Incio are mines of iron, which is manufactured chiefly in Lugo and Mondoñedo; antimony is found in Castroverde and Cervantes; and argentiferous lead in Riotorto. Among the mineral products of the province may also be reckoned the gold washed down by the streams. There are quarries of granite, marble, various kinds of slate and building stone. Linen and woollen cloths are manufactured to some extent. The export traffic of Ribadeo, Vivero, Santiago, Foz, and San Ciprian, is considerable; but the inland trade, from the causes already mentioned, is insignificant, and carried on chiefly by the maragatos. Education is in a deplorable state. There is a university, so called, at Santiago; but there are very few primary schools, and those are of no great excellence. In the *partido* of Ribadeo there can scarcely be said to be any educational provision whatever. Lugo contains eleven *partidos*, of which the total population

amounted in 1845 to 323,158. The inhabitants of this sequestered region have preserved to a striking degree the manners and customs of ancient Galicia. They are a laborious, loyal, and obedient people; much addicted to litigation, however, and somewhat given to less excusable methods of revenge. The climate of the province is various, on account of the extreme unevenness of its surface; in general it is mild, however, and especially on the coast.

LUGO, the capital of the above province, is situate in N. Lat. 43. 5., W. Long. 7. 57., on a small hill near the River Miño, about 2118 feet above the level of the sea, 50 miles S.E. from Coruña, and 294 N.W. from Madrid, on the highway between these two cities. Lugo was at one time a city of great importance. Its name is supposed to be connected with its ancient destination as the site of a grove temple. It was the headquarters of the Roman occupation of the region, and was known as *Lucense*, or *Lucus Augusti*. They surrounded the city with a lofty and massive wall, most of which is still standing, and constitutes one of the most remarkable Roman monuments in Spain. It is supported at intervals by strong semicircular towers, which numbered eighty-five previous to the repairs in 1809. It serves at present as a promenade, commanding an extensive and delightful prospect. Lugo suffered greatly in the fifth century during the Moorish wars, and more recently in the war of independence, lying so much in the way of the combatants. The town consists of about 700 houses; it is not compactly built, a good deal of space being taken up with gardens and orchards. The principal public places are,—the Plaza Mayor, a spacious square with porticos on one side; the Plaza de Santo Domingo; the Plaza del Hospital, where reviews are held; and the Campo de San Roque, a place of much resort, where fairs and markets are held.

The most remarkable of the public buildings is the cathedral, situate south of the city, the primitive construction of which dates from the twelfth century, though it has been restored and repaired at various periods, and is still, in some parts, unfinished. The bell-tower and peal of bells, and the carving of the choir, by the famous Galician artist of the sixteenth century, Alonzo Moure, are remarkable. The episcopal palace, the civil hospital, the prison, and the barrack, are the remaining buildings of note. The educational institutions are,—a normal school in the ex-convent of the Dominicans, and a recently established college (*Instituto de Segunda Enseñanza*), which also contains a school of design, museum of natural history, and botanic garden. Attached to this institution is a library of about 7000 volumes, formed of the episcopal library and the books of the suppressed convents. About a mile south of the town, on the left bank of the Miño, are the famous baths of Lugo,—a thermal spring, of sulphurous ingredients, over which in 1847 was erected by the government an excellent and capacious bathing-house. The remains of Roman baths are found here, and the massive wall which they built to defend their erection from the inundations of the Miño still exists almost entire. These baths are resorted to on account of their beneficial influence in paralytic and syphilitic disorders. Pop. (1847) 7269.

LUKE, St, the Evangelist. His Greek name Λουκᾶς is a contraction of Λουκαῖός, *Lucanus*, and indicates that Luke was descended from heathen ancestors, and that he was either a slave or a freedman. Respecting the place and time of his birth we have no certain information. According to ecclesiastical tradition, the author of the Gospel is the same Luke who is mentioned in Paul's epistles (Philem. 24; 2 Tim. iv. 11; Coloss. iv. 14), and who is called, in the last-mentioned passage, "the physician." This tradition is confirmed by the Acts of the Apostles, according to which the author of that work accompanied the apostle Paul in his journeys (Acts xvi. 10, sq.; xx. 5-13; (Acts xxi. 1-17; xxvii. 28). The profession of a physician

Lugo
||
Luke.

Luke. harmonizes also with the condition of a freedman, indicated by the form of the name.

To those who excuse their disbelief of the miracles recorded in the Gospels by the assertion that their authors were ill-informed Jews, greedy of the marvellous, it must appear of some importance to meet in Luke a well-informed Greek, skilled even in the medical sciences. The higher degree of his education is further proved by the classical style in which the proœmium to his Gospel, and the latter portion of the Acts, are written; and also by the explicit and learned details which he gives in the Acts on various antiquarian, historical, and geographical subjects. The classical, connected, periodic, and sustained style of the introduction to the Gospel of St Luke differs so strikingly from the Hellenistic Greek of the history itself, that we clearly perceive that he made use of written documents. He did not, however, transcribe verbatim from them, nor did he merely write down verbal traditions; for we find the same characteristic phraseology which belongs to St Luke's individual style both in the Gospel and in the Acts.

It appears to be doubtful whether Luke had the Gospel of Matthew before his eyes, since in the history of the birth of Jesus he seems to have made use of documents referring to the family of Mary, while the accounts given by Matthew refer more to the family of Joseph. This is also confirmed by the aphoristic mode in which he reports the Sermon on the Mount. The Gospel of St Luke contains exceedingly valuable accounts, not extant in the books of the other evangelists; for instance, those concerning the childhood of Jesus, the admirable parables in chapters xv. and xvi., the narration respecting the disciples at Emmaus, the section from chap. ix. 51 to xix. 27, which contains particulars mostly wanting in the other evangelists.

The statement of Luke at the beginning of his Gospel must dispose us favourably with regard to its historical-credibility. He states that he had accurately investigated the truth of the accounts communicated, and that, following the example of the *πολλοί*, he had made use of the statements of eye-witnesses. Luke had frequent opportunity of meeting these eye-witnesses when he travelled with Paul. He himself reports, in Acts xxi. 18, that he met James. He gives also, with greater accuracy than the other evangelists, some chronological notices, such as those at the beginning of chapters ii. and iii., and in Acts v. 37. As to the statements of the ancients concerning the date or time when the Gospel of St Luke was written, we find in Irenæus (*Adv. Hær.* iii. 1), that Mark and Luke wrote after Matthew. According to Eusebius (*Hist. Eccles.* vi. 28), Origen stated that Luke wrote after Matthew and Mark; but Clemens Alexandrinus, according to the same writer (*Hist. Eccles.* vi. 14), asserted, on the authority of "the tradition of the earlier elders," that the Gospels containing the genealogies were written before the others. Eusebius (*Hist. Eccles.* iii. 24), in reference to the Gospel of John, says:—"John properly passed over in silence the genealogy according to the flesh of our Saviour, which was detailed by Matthew and Luke." De Wette, in his *Introduction to the New Testament*, endeavours to infer from the definiteness with which the destruction of Jerusalem is predicted, &c., that this Gospel was written some time after the destruction of the city had taken place. On this we merely observe that a *petitio principii* runs through the whole train of the argument, since it sets out with assuming the impossibility of detailed predictions. From the circumstance that the book of Acts leaves St Paul a captive, without relating the result of his captivity, most critics have, with considerable probability, inferred that Luke accompanied St Paul to Rome, that he employed his leisure while there in composing the Acts, and that he left off writing before the fate of Paul was decided. Now, since the Gospel of St Luke was written before the Acts, it

seems to follow that it was written a considerable time before the destruction of Jerusalem. The most ancient testimonies in behalf of Luke's Gospel are those of Marcion, at the beginning of the second century, and of Irenæus, in the latter half of that century. A good separate commentary on the Gospel of Luke is still a desideratum. Kuinoel's *Commentarius in Evangelium Lucae* (1843) is not quite satisfactory; nor Bornemann's *Scholia in Lucam* (1830); much less Baumgarten-Crusius (1845).

Besides the Gospel which bears his name, Luke wrote the Acts of the Apostles. In those portions of the Acts in which Luke speaks as the companion of Paul, and consequently as an eye-witness, his Greek style is more classical than in the rest of the work. This circumstance supports the opinion that Luke followed some written documents in the earlier part of the Acts, as well as in the Gospel. Compare Riehm, *De fontibus Act. Apost. Traj.*, 1825; and Kling, *Studien und Kritiken*, 1837, Heft 2.

That the accounts of Luke are authentic may be perceived more especially from a close examination of the inserted discourses and letters. The characteristic marks of authenticity in the oration of the Roman lawyer Tertullus, in ch. xxiv., and in the official letters in ch. xxiii. 26, sq.; xv. 23, sq.; can scarcely be overlooked. The address of Paul to the elders of the Ephesian church is characteristically Pauline, and even so full of definite allusions and of similarity to the Epistle to the Ephesians, that it furnishes a confirmation of the authenticity of that letter which has sometimes been questioned. Respecting these allusions, see an essay of Tholuck in the *Studien und Kritiken*, 1839, p. 306, sq. As for the testimonies in behalf of the authenticity of the Acts, they are the same as for Luke's Gospel. Clemens Alexandrinus, Irenæus, and Tertullian, expressly mention the Acts, and Eusebius reckons them among the Homologoumena. The most complete commentaries on the Acts are those of Kuinoel and Baumgarten; but equally valuable are Neander's *Planting and Training*, Schaff's *Apostolic History*, and Wieseler's *Chronologie der Apostolschen Zeitalter*.

LULLI (or LULLY), GIOVANNI BATTISTA, a musician of celebrity, was born at Florence in 1633. According to the letters of naturalization granted to him in France by Louis XIV., in December 1661, Lulli was the son of a Florentine gentleman, and not of a peasant, as has been so often asserted. In these letters, and in other public documents, his name is spelled Lully, and also in his own signature; but it seems probable that the final letter of his Italian surname became changed in France. He was about twelve years old, and had learned to play on the guitar, when the Chevalier de Guise, then travelling in Italy, happened to see him, and being struck by the lively intelligence of the boy, offered to take him to France, promising to provide for him. Lulli's father being poor, gladly accepted the offer. Mademoiselle de Montpensier, a niece of Louis XIV., had expressed to the chevalier a wish to obtain a pretty Italian boy as a page. Lulli, however, was not pretty, but very dark and coarse-featured; so that when the chevalier presented him to her, the poor boy found no favour in her eyes, but was immediately placed in her kitchen as an under-scellion. He employed his leisure hours in learning the violin, and his extraordinary musical capacity having been remarked, he was made one of mademoiselle's musicians, and soon distinguished himself by his violin playing, as well as by the airs that he composed. But happening to compose an air for some very coarse satirical verses written against his patroness, she was so highly offended that she dismissed him from her music band. Soon afterwards he contrived to obtain admission into the violin band of the king, who, having heard him play in 1652, was so much pleased as to appoint him inspector-general of the royal violin band, and also to institute for

Lulli.

Lully. him a new band of violins called the little band, to distinguish it from the great band of twenty-four violins. Lully wrote a great many pieces for his violin band, and was at that time considered the best violinist in France. Before the French opera was established, the king gave annually grand spectacles called *ballets*, made up of dances, recitations, &c. Lully now commenced the study of musical composition, and wrote the airs for those *ballets* in which the king danced. Forming an intimacy with Molière, Lully composed music for several of that great dramatist's pieces; and from that time continued to compose and direct all the music of Molière's theatre. For several years he acted and danced in the court *ballets*; and at the request of Molière performed with great applause some parts in the latter's comedies. Lully became so great a favourite at court that Louis would listen to no other music but his. In the space of twenty years, Lully, besides receiving numerous presents, obtained nine valuable privileges; and, in 1672, a patent for establishing at Paris a royal academy of music, known afterwards as "The Opera." This was the beginning of Lully's splendid career of fame and fortune. He turned all his powers to the direction and improvement of this new establishment, and composed for it the music of nineteen operas, which remained in vogue for many years. After his death the new opera fell into debt and ruin. Lully led a gay and voluptuous life among the grandees of his time at the French court. It appears that his death was caused by an injury to one of his feet. Having composed a *Te Deum* on the recovery of Louis from sickness, Lully conducted its performance on 8th January 1687, and, while beating the time, accidentally struck his foot with the point of his cane. An abscess ensued, which a bad habit of body rendered fatal. He died at Paris on the 22d March 1687. Some of his biographers represent his conduct and character as in all respects odious. Basely servile to his superiors, brutally insolent to his inferiors, meanly jealous of all other musicians of merit, and unscrupulous in compassing their ruin; a false friend and a tyrannical master; selfish and avaricious in all his dealings; such is the portrait given to us of a spoiled *parvenu* Italian at the court of Louis XIV. But in judging of Lully's career, circumstances of place and time ought to be considered. The blind favouritism of Louis, and the bad example of his courtiers, offered no good school of moral training to the poor Italian boy. Lully married in 1662 Mademoiselle Lambert, who bore him three sons and three daughters. He had a large income from various sources; and after his death the inventory of his effects proved his wealth. His silver plate was valued at 16,707 livres; his jewels, &c., 13,000 livres; his ready money, 250,000 livres; his moveables at the opera, 11,000 livres; and the house itself, 80,000 livres. Besides these, the rents of several houses, 4600 livres a year; and on 3d April 1687, his widow sold his place of royal secretary for 71,000 livres: a wonderful contrast to the condition of Lully when he was under-sculion in the kitchen of Mademoiselle de Montpensier! Although there was nothing peculiarly original in the style and form of Lully's music, he possessed a feeling for dramatic expression which caused his operas to survive so long in France after his death. The last performance of one of his operas was in 1778; and in the same year three of Gluck's operas, with some of Piccini's and Paisiello's, were performed. These new and original works, in a style so different from Lully's, produced a great effect on the Parisians; and thenceforward Lully's operas were no more heard. Nineteen of Lully's operas were published in score; and his portrait is prefixed to his opera of *Acis et Galatée*. (G. F. G.)

LULLY, RAYMOND, surnamed the "Enlightened Doctor," a philosopher and theologian of eccentric character and singular enthusiasm, was born at Palma, in the island of Majorca, about 1235. In early life he espoused the pro-

fession of arms under James I. of Arragon, at whose gay Lunawara court he is said to have led a somewhat irregular life. His mind took a serious turn about the age of 30, when he retired to a desert, and, amid solitude and asceticism, gave himself up for nine years to the study of theology, to prepare himself for the duties of a missionary. Directed, as he alleged, by a vision from Christ to convert the Mohammedans, he learned Arabic from a slave; and it was on becoming acquainted with the philosophy of Averroës that he probably conceived his scheme of dialectics, by which he hoped at once to revolutionize science and the world. His *Ars Lullia* was now published (1276), at the express command of a fiery seraph which appeared to him; and having prevailed upon his former patron of Arragon to establish a convent at Palma for the education of missionaries to the infidels, he went to Rome ten years afterwards to solicit the aid of Pope Honorius IV. in carrying out a crusade against the worshippers of Islam. The death of his holiness compelled Lully to look for aid elsewhere, and he accordingly visited Paris and Genoa, but without success. Having crossed to Africa, he engaged in a discussion with a Mohammedan, which almost cost him his life. He left the country for a time; but soon made his appearance again, when he was nearly stoned to death, and afterwards cast into prison. Liberated on the intervention of some Genoese merchants, he returned to Europe, and busied himself in preaching in behalf of a crusade for the recovery of the Holy Land. His success was not equal to his zeal; and the fiery and unquenchable enthusiasm of Lully urged him to make a third single-handed attack upon the unbelievers of Africa, when he died a martyr to his devotion for their conversion, at Bougiah, in Algeria, in 1315, at the mature age of 80 years.

The *Ars Magna* ("Great Art"), as the admiring followers of Lully termed it, consisted in a determination, *a priori*, of all the forms and of all the possible combinations of thought; a complete arsenal of universal argumentation; a reducing of science to a number of general signs; the solution, in short, of all questions, human and divine, by a simple piece of mechanism resembling a calculating machine! His most celebrated follower was the unfortunate Giordano Bruno. Frivolous in many respects as his invention was, it nevertheless was a protest against the idle methods of the schools, which led him to be regarded as a reformer in philosophy. The end Lully had in view was the union—the complete assimilation—of philosophy and theology; and his powers neither as a philosopher nor as a theologian were able to free him from the inextricable confusion into which his method led him. He united the chivalrous ardour of the crusader to the pedantry of the schoolman; the mystical exaltation of one inspired to the strict and methodical habits of the logician. His personal character claims our admiration for the unconquerable resolution and devoted zeal with which he strove to disseminate what he believed to be the truth. The most complete edition of Lully's works is that of Bucholius and Salzinger, 10 vols. folio, Mayence, 1721.

LUNAWARA, a town of Hindustan, in the province of Gujerat, and district of the Rewa Caunta, situate near the confluence of the Panum with the Myhee River. It is the capital of a native principality of the same name. Here, in 1803, a treaty was concluded with the rajah by the British government, which freed him from the tribute he had before paid to Scindia. Sir George Barlow, in 1806, severed the connection, whereupon the territory again became subject to Scindia, who revived his demand of tribute. In 1819 the right of supremacy over Lunawara was ceded by Scindia to the British government; the latter guaranteeing the payment of the tribute on condition that Scindia should forthwith withdraw from the state, and refrain from further interference in its affairs. The town is situate in

Lund

Lunel.

N. Lat. 23. 8., E. Long. 73. 37. It is 65 miles E.N.E. from Ahmedabad.

LUND, a town of South Sweden, situate in an extensive plain in the laen of Malmö, 8 miles from the Sound, and 24 miles E. from Copenhagen. The town is of high antiquity, and in pagan times is said to have had a population of 80,000. It is now chiefly remarkable for its university, founded by Christian I. of Denmark in 1479. It has faculties of philosophy, law, medicine, and theology, and is attended by about 600 students. The library contains upwards of 70,000 vols. and about 2000 MSS. There are also collections of natural history, coins, antiquities, &c. Puffendorff was professor of the law of nature and nations here; and Linnaeus was for some time a pupil. The present building was erected in 1666. The cathedral is a large irregular structure, said to have been founded about the eleventh or twelfth century, but since then has been frequently altered. Lund, at present the seat of a bishop, was in the middle ages the seat of an archbishop, who was considered the primate of the north. On a hill about half a mile from the town, the Scandinavian monarchs were elected sovereigns of Scania. The chief manufactures of the town are woollen cloth, leather, and tobacco. Pop. about 5000.

LUNDY ISLAND, a small precipitous island lying off the N. coast of Devonshire, in the Bristol Channel, opposite Bideford Bay, and about 9 miles N.W. of Hartland Head. It is $2\frac{1}{2}$ miles in length from N. to S., by $1\frac{1}{2}$ in width, and contains an area of 920 acres. It consists almost entirely of granite, which rises in lofty cliffs from the sea, affording only one narrow landing-place on the S.E. side, near Rat Island. Here, however, there is a safe anchorage in from 5 to 12 fathoms of water. The land is laid out in pasturage, and swarms with rabbits; while the rocks are inhabited by vast numbers of sea-fowl, especially puffins. This island was originally held by a pirate, named Morisco, in the beginning of the thirteenth century, who erected a fortress on it, which was afterwards garrisoned by Lord Say for Charles I. A lighthouse, with an intermittent and fixed light, stands on the southern extremity, near the ruins of St Anne's chapel. Pop. (1851) 34, chiefly employed in shooting rabbits and sea-fowl for the skins and feathers.

LÜNEBURG, a town of Hanover, capital of a province of the same name, on the left bank of the Ilmenau, and on the Hamburg and Hanover Railway, 82 miles N.N.E. of the latter. It is surrounded by old walls, having six gates, and is a dull, ill-built town, the streets being narrow and dark, and the houses old-fashioned. The principal public buildings are,—the royal palace, the town-hall, St Michael's church, underneath which are the burial vaults of the old dukes of Lüneburg, St John's church, the exchange, and the cavalry barracks. The academy for the education of young noblemen occupies the old convent of St Michael, and has a museum, and a library of about 15,000 volumes. The River Ilmenau, which falls into the Elbe about 10 miles below the town, is here navigable, and by means of it Lüneburg carries on a considerable trade in the products of the surrounding country. Lime-burning and the making of salt constitute the chief branches of industry, the materials for which are abundant in the neighbourhood. Pop. 12,400. The province of Lüneburg is an immense sandy plain, chiefly covered with heath, moor, and forest, mostly of fir. Along the banks of the rivers, particularly the Aller and Elbe, occur some fertile land. Flax is cultivated; but the quantity of corn produced is not sufficient for the wants of the people. The breeding of cattle is much attended to, and sheep are very numerous. Many of the inhabitants derive a great portion of their subsistence from the keeping of bees. Area 4326. Pop. (1852) 338,764, almost all Lutherans.

LUNEL, a town of South France, department of Hérault, near the right bank of the Vidourle, and on the canal which terminates in the Mauguio lagoon, 16 miles S.W. of Nîmes

by railway. It stands on a level plain, which is subject to inundations in the spring, and is very unhealthy in the heat of summer. The only objects of interest are a beautiful fountain, a barrack, and a small botanic garden. In the vicinity a famous kind of sweet wine is made; while, by means of the canal, a brisk trade is carried on in brandy, raisins, grain, and wool. Lunel was formerly strongly fortified, and was several times besieged in the Huguenot wars. Its defences were afterwards razed by order of Cardinal Richelieu. Pop. (1850) 6392.

LUNETTE, in *Fortification*, a work with two faces and two flanks. It is frequently employed as a form of outwork, designed for the defence of avenues, farm-houses, bridges, the curtains of field-works, &c. (See *FORTIFICATION*.)

LUNÉVILLE, a town of France, capital of an arrondissement in the department of Meurthe, on the right bank of the Meurthe, at its junction with the Vezouze, 20 miles E. by S. of Nancy by railway; N. Lat. 48. 35., E. Long. 6. 29. It is regularly laid out, the streets being generally straight and the houses well built. A palace was built here by the Duke of Lorraine in the beginning of the eighteenth century. It is now a cavalry barrack, with accommodation for 6000 horses, and its gardens have been converted into public promenades. Attached to this barrack, which is the largest of its kind in France, is a riding-school, with an extensive exercising ground. The chief of the other public buildings are,—the parish church, hospitals, college, synagogue, and theatre. The inhabitants manufacture embroidery, delf ware, gloves, and hosiery; and carry on a trade in grain, hops, wine, hemp, and wood, by means of the Paris and Strasbourg Railroad which passes the town. Lunéville, though once a town of some importance, has of late decayed considerably. During the wars between the dukes of Burgundy and Lorraine it was strongly fortified, and sustained numerous sieges. A French army, however, in 1638 entered the town and levelled the fortifications. In the beginning of the eighteenth century it was the residence of Duke Leopold of Lorraine, and afterwards of Stanislaus, ex-King of Poland, both of whom did much to improve the appearance of the town. Pop. (1851) 12,476.

LUPERCALIA, an ancient Roman festival in honour of Lupercus, the god of fertility, seems, from its rude and uncouth ceremonies, to have been introduced by shepherds at a very early date. On the 15th of February, the day of the festival, the Luperci, or priests of Lupercus, assembled at the Lupercal, the spot where the she-wolf is supposed to have suckled Romulus and Remus. There they sacrificed goats and young dogs—animals supposed to be acceptable to the god of fertility, on account of the strength of their sexual appetite. Two youths of noble birth were then led forward; their brows were first stroked by a sword dipped in the blood of the victims, and afterwards washed with wool saturated in milk. The young men meanwhile laughed as often as they were touched. After feasting plentifully, the Luperci cut into shreds the skins of the goats that had been sacrificed. With some of these pieces they covered part of their body, leaving the rest naked, in imitation of Lupercus. With others shaped into thongs, they ran wildly through the streets, lashing every one they met. To these lashes women often submitted voluntarily, since they believed them a preventive against barrenness and severe pangs in child-bearing. That the ceremonies of the Lupercalia were originally intended to symbolize the purification of the people, is evident from the fact that Lupercus was styled, *Februus*; his festival day, *dies februata*; the month in which that day occurred, *februarius*; and the goat-skin used, *februum*. In course of time, however, the festival came to be regarded simply as a relic of antiquity, and as such continued to be observed as late as the reign of Anastasius. It seems to have been also celebrated in other towns of Italy and in Gaul.

Lunette
Lupercalia

Lurgan
||
Lustration.

The Luperci were originally chosen from the patricians, and are supposed to have been instituted by Romulus and Remus. These princes divided the order or college into two classes; and after the names of their own respective followers, styled them Quinctiliani, or Quinctilii, and Fabiani, or Fabii. A third class, called Julii, was added by Julius Cæsar; and to these, and possibly to the other divisions also, he assigned certain revenues, which were afterwards discontinued. The office of the Luperci was not a life appointment, but how long it continued is unknown.

LURGAN, a market-town of Ireland, county of Armagh, on the Belfast and Armagh high road, 21 miles W.S.W. of the former, and 2 miles from the southern shore of Lough Neagh. It stands on a gentle eminence, and commands an extensive view of the neighbouring country and lake. The town chiefly consists of a wide, well-built street, and contains a handsome parish church, with chapels belonging to the Roman Catholics, Presbyterians, and others. There are also several schools, a court-house, bridewell, linen-hall, and market-house. The manufactures comprise linens, especially damasks and diapers, tobacco, beer, and whisky. Lurgan was founded in 1619 by the Brownlow family; but in 1641 it was burned to the ground, and although afterwards rebuilt, was again destroyed by the army of James II. It was, however, laid out anew, and soon became a thriving manufacturing town. Market-day, Thursday. Pop. (1841) 4677, (1851) 4211.

LUSATIA (German *Lausitz*), was anciently a margraviate of Germany, lying between Brandenburg, Sillesia, Bohemia, and Saxony, and having an area of about 4200 square miles. It was instituted in 931, but after various changes was annexed to Bohemia in 1370. In 1635 it was ceded by Ferdinand II. to the electorate of Saxony. By decision of the Congress of Vienna, in 1815, Saxony was obliged to cede the whole of Lower, and also a portion of Upper Lusatia to Prussia. The remainder of Upper Lusatia now forms the Saxon province of Bautzen.

LUSITANIA, a district of ancient Hispania. Considered in its original meaning as the country of the Lusitani, it is said by Strabo to have been bounded on the S. by the Tagus, and on the W. and N. by the sea. In the course of time, however, the growing importance of the Callaici on the N. narrowed its extent, and fixed the River Durius (*Douro*) as its northern boundary. Again, in consequence of the multitude of Lusitanians that were driven southward during their protracted struggle with the Romans, the name Lusitania was gradually extended to those districts S. of the Tagus. Accordingly, when fixed by Augustus as one of the three provinces of Hispania, Lusitania was comprised between the Anas (*Guadiana*) on the E., the sea on the S. and W., and the Durius on the N. The chief river within the district is the Tagus, which flows westward into the Atlantic Ocean. The following are the principal towns on the rivers:—On the Anas, Metellinum (*Medellin*), Emerita Augusta (*Merida*), the Roman capital Pax Augusta (*Badajoz*), and Myrtilis (*Mertola*); on the Tagus, Libora (*Talavera de la Reina*), Norba Casarca (*Alicantara*), Scalabis (*Santarem*), and Olisipo (*Lisbon*), the ancient capital previous to the time of the Romans; and on the Munda (*Mondego*), Conimbriga (*Coimbra*). The other towns are,—Salmantica (*Salamanca*), Sancia Transcudana (*Ciudad Rodrigo*), Ebora (*Evora*), and Pax Julia (*Beja*). The Lusitanians, especially those that inhabited the mountains, were much addicted to plunder. Of all the Iberians, they were the bravest, and offered most resistance to the Romans.

LUSTRATION, in *Antiquity*, sacrifices or ceremonies by which the ancients purified their cities, fields, armies, or people, defiled by any crime or impurity. Some of these lustrations were public, and others private. There were several ways of performing lustration, viz., by fire, by sul-

phur, by water, and by air; the last being done by fanning and agitating the air round the thing to be purified. Some of these lustrations were necessary, and could not be dispensed with, as lustrations of houses in time of a plague, or upon the death of any person; others, again, were performed from choice, and at pleasure. The most of the Roman lustrations were not intended to atone for crime, but to secure the blessings of the gods. The public lustrations at Rome were celebrated every fifth year, in which they led a victim thrice round the place to be purified, and in the meantime burned a great quantity of perfumes. The country lustrations were celebrated when sowing was finished, and before the peasants began to reap the corn; in those of the armies, called *armilustria*, some chosen soldiers, crowned with laurel, led the victims—a cow, a sheep, and a bull—thrice round the army ranged in battle-array in the field of Mars, to which deity the victims were subsequently sacrificed, after pouring out many imprecations upon the enemies of the Romans. The lustrations of the flocks were designed to preserve the flock from disease, contagion, &c., and were performed in this manner:—The shepherd sprinkled them with pure water, thrice surrounded his sheepfold with a composition of savin, laurel, and brimstone set on fire, and afterwards sacrificed to the goddess Pales an offering of boiled milk, wine, a cake, and millet. As for private houses, they were lustrated with water, a fumigation of laurel, juniper, olive tree, savin, and the like; and the victim was commonly a pig. Lustrations made for particular persons were commonly called *expiations*, and the victims *piaculu*. There were also for infants a kind of lustration by which they were purified,—girls on the third, and boys on the ninth day after their birth; a ceremony which was performed with pure water and spittle. They cast into the river, or at least out of the city, the animals or other things which had served for a lustration or sacrifice of atonement; and thought themselves threatened with some great misfortune when by chance they trod upon them. Part of these ceremonies were abolished by the Emperor Constantine and his successors; the rest subsisted till the Gothic kings became masters of Rome, when they expired. (See Hartung, *Die Religion der Römer*.)

LUSTRUM, was a lustration or purification of the Roman people, by one of the censors in the Campus Martius, after the census, which was taken every five years, had been completed. This custom was first instituted by King Servius Tullius B.C. 566, and was afterwards kept up with great regularity at the periods just specified. In the earliest period of the Roman republic the census was taken, and the lustrum solemnized, not by the censors, as was afterwards the custom, but by the consuls. We gather from Livy (iii. 22, xxiv. 43), that the census sometimes took place without the lustrum being performed, owing probably to some great calamity which had happened to the republic. For the determination of the time when the lustrum took place, see Niebuhr, *Hist. of Rome*, i., p. 277.

LUTE, a substance used for making vessels or apparatus air-tight, by closing the apertures of their joints, or for coating, so as to enable them to bear a higher temperature, or for repairing a fracture. Clay is the basis of many lutes; whence the term from *lutum*, clay. Among the principal lutes are *Stourbridge clay*, in fine powder, made into a paste with water; *Windsor loam*, a natural mixture of clay and sand; *Willis's lute*, a thin paste made of a solution of borax in boiling water, with slaked lime. Mixtures of borax and clay also form useful lutes. What is called *fat lute*, is a mixture of pipe-clay with drying linseed-oil. Caustic lime, furnishes, by admixture with other bodies, a variety of lutes. A mixture of lime and white of egg, or glue, forms a powerful cement. *Iron cement* (described under GAS-LIGHT) is useful for making joints tight, as is also white-lead, ground

up with oil and spread on strips of cloth. Among the other substances used as lutes, may be mentioned moistened bladder, paste and paper, paper prepared with a mixture of wax and turpentine, linseed-meal, and caoutchouc. The last-named substance is in extensive use for making chemical joints or elastic connectors, getting rid of that rigidity which in a complicated arrangement of apparatus is so liable to lead to accident. (C. T.)

LUTE, a stringed instrument of music, long since superseded by the harp and the guitar, but for centuries very fashionable in Europe. The music for the lute was written

in tablature. Any person who wishes to become acquainted with the nature of the lute and its mysteries of stringing, tuning, notation, and playing, may consult Thomas Mace's *Musick's Monument*, published at London in 1676. Most of the MS. lute music in tablature is so carelessly and incorrectly written, as to offer serious difficulties to any person who would translate it into modern notation. The writer of this article may refer to the *facsimile* extracts which he made from Gordon of Straloch's *Lute Book*, and from Dr Leyden's *Lyra-Viol Book*, and presented to the Library of the Faculty of Advocates, Edinburgh, in 1847. (G. F. G.)

Luther.

L U T H E R.

LUTHER's life is both the epos and the tragedy of his age. It is an epos because its first part presents a hero and a prophet, who conquers apparently insuperable difficulties, and opens a new world to the human mind, without any power but that of divine truth and deep conviction, or any authority but that inherent in sincerity and undaunted, unselfish courage. But Luther's life is also a tragedy: it is the tragedy of Germany as well as of the hero, her son, who in vain tried to rescue his country from unholy oppression, and to regenerate her from within, as a nation, by means of the gospel; and who died in unshaken faith in Christ and in his kingdom, although he lived to see his beloved fatherland going to destruction, not through, but in spite of, the Reformation.

Both parts of Luther's life are of the highest interest. In the epic part of it we see the most arduous work of the time,—the work for 200 years tried in vain by councils and by prophets and martyrs, with and without emperors, kings, and princes,—undertaken by a poor monk alone, who carried it out under the ban both of the pope and the empire. In the second, we see him surrounded by friends and disciples, always the spiritual head of his nation, and the revered adviser of princes and preacher of the people; living in the same poverty as before, and leaving his descendants as unprovided for as Aristides left his daughter. So lived and died the greatest hero of Christendom since the apostles; the restorer of that form of Christianity which now sustains Europe, and (with all its defects) regenerating and purifying the whole human race; the founder of the modern German language and literature; the first speaker and debater of his country; and, at the same time, the first writer in prose and verse of his age.

And in what state had he found his native country? The once free and powerful aggregate of nations, which had overthrown the western empire, conquered Gaul, and transfused healthier blood into the Romanized Celtic population of Britain, had gradually been broken up into nearly 400 (with the barons of the empire, 1200) sovereignties, under a powerless imperial government represented by emperors bent upon the destruction of nationality, and by an oligarchic diet with seven electoral princes at its head, three of whom, as ecclesiastics, were creatures of the pope, while the remaining four, imitating the emperor, were occupied rather with the selfish interests of their princely Houses than with those of their country. When, in 1486, Maximilian was to be elected king of the Romans, and when he became emperor (in 1493), Archbishop Berthold, elector of Mayence, a great and patriotic man, had prepared, with some other German princes, a plan for a sort of national executive, the members of which were not to be installed, as heretofore, by the emperor alone, but appointed by the Diet and the electors, in order to form a federal senate to co-operate with the emperor. But the Austrian prince, son-in-law of Charles of Burgundy, and heir to his kingly estates, was liberal in promises unfulfilled, having lived not only to maintain but to strengthen the im-

perial autocracy. His great comfort on his death-bed was the reflection that his whole life had been devoted to the aggrandizement of his own House of Austria. The smaller German lords and knights of the empire made a last attempt to maintain their independence, and to restore the ancient liberties of the German nation; but acting in a lawless manner and without any political wisdom, they were crushed by the united power of the emperor and the electors. The more eminent and powerful portion of the mass of the nation was represented by the wealthy towns, which had purchased from the emperors the privileges of free imperial cities; and which, with the Hanseatic towns, would have formed, united with the estate of the knights, the most complete constituent parts of a House of Commons, by the side of the princes, dukes, and counts of the empire as House of Peers. The formation of such an effective federal empire must have been in the mind of those enlightened men, who, at the election of Maximilian, perceived that a constitution was necessary to prevent Germany from becoming a mere domain of the emperors. A truly representative government, federal and unitary, monarchical and aristocratical and popular, would have followed, as a matter of course, from such a beginning as that proposed. But since the failure of that plan nothing effectual had been accomplished; isolation and separation became more complete; the peace of the land was enforced at last, although imperfectly; and the imperial tribunal established by Maximilian acted with insufficient authority, and, as was believed, not with equal justice. The greatest iniquity was the condition of the peasantry. The freeholders had in many parts of Germany been, if not absorbed, at least considerably diminished by the feudal system; but the great grievances were the illegal abuses which had grown out of that system and the always increasing exactions of the lords of the manor, who, particularly in Southern Germany, had reduced the peasants to real serfs,—men who had to render unlimited services and scarcely could support life. There had been insurrections of peasants particularly along the Upper Rhine in 1491 and again in 1503; but being without leaders, they were each time crushed after a bloody struggle, and the ultimate result was a still greater amount of hardship. The chains of the sufferers were riveted. In short, Germany was suffering from all the same evils as France and England without having gained that unity and strength of government which in those countries had resulted from similar struggles. On the other hand, however, the age was one of general progress. The invention of printing had given wings to the human mind; philology had opened the sources of historical knowledge as well as of philosophy and poetry; astrology began to give way to astronomy, and the idea of the universe emerged out of Jewish and other fables. As to Germany in particular, the cradle of the art of printing, Augsburg and other great cities were, with the Hanseatic towns, centres of European commerce, and partook of the resources opened by the discovery of America. The religious mind, too, had been

Luther. awakened since the days of Wycliffe and of Huss. Believing Christendom, and, above all, believing Germany, had hoped for a real reform of the church, the abuses of which were doubly felt in consequence of the shameful immorality of the popes, and the ever-increasing exactions of the court of Rome. The issue of immense efforts on the part of emperors, princes, and people, was, that the council of Constance delivered Huss to the flames, and both the councils of Constance and Basle ended in a more decided supremacy of the Roman pontiffs. Certainly the religious mind of Germany was not a little damped by these disappointments; but the thirst after a reform was not quenched by the evident unwillingness of Rome to reform itself. The wise and good men of the time, however, could not discover any means to achieve what was generally desired and demanded. The faith in human, and gradually also in divine justice upon earth, had long disappeared in unfortunate Italy, as the writings of the age prove; but now it threatened to vanish even in the minds of the Germans, in whom that faith may be called eminently their innate individual and national religion. The Bible had been repeatedly printed in the vernacular tongue, but it was, and continued to be, a book closed with seven seals. There was a general feeling that the gospel ought to be made the foundation of purified religion and doctrine; but where was the man to resuscitate its letter and spirit, and to find the way from Christ to the soul through the darkness and the fictions, the usages and the abuses, of the intervening centuries? The voice of the Friends of God with Tauler at their head had been choked in blood, like that of the Waldenses; and then, supposing such an evangelical basis to have been found, was the existing state of injustice and wrong to continue? Were the emperors to continue to sacrifice the empire to their dynastic interests,—the princes and the nobles to their covetousness and licentiousness? Yes; would not the overthrow of the ecclesiastical power lead to universal conflagration, and rebellion and destruction, and thus Christendom be thrown back into a worse barbarism than that out of which they were anxious to emerge? In short, the work (so it seemed) could not be undertaken but in despair or in enthusiastic faith. In the former case it must succumb necessarily; but even if begun with the faith of Wycliffe and of Huss, would not the attempt in any case lead to a long-continued struggle, the end of which none of those who began it could live to witness? Who should enter on so tremendous a course?

Such was the work to be done, and such were the general and peculiar difficulties and the state of things in Germany, when Luther undertook it. Luther devoted a life of almost supernatural energy and suffering to secure its basis; and although at his death he left it surrounded by the greatest dangers, and one hundred years of bloody struggle were succeeded by another hundred years of agony and of exhaustion, still the Reformation survived, and proved essentially the renovating element of mankind instead of being (as its enemies prophesied) the promoter of revolution. It subsists to this hour as the only durable preserver of all liberties religious or political; and the nations and states which have embraced the Reformation are those only which have escaped the revolutions which for seventy years have agitated those of the Roman faith.

The life of him who was the beginner of this great and holy work, and who broke down the double tyranny of pope and emperor arrayed against him, must therefore be considered from a higher point of view than that of individual biography, or sectarian panegyric, or national vanity and prejudices. The article upon Luther will have to be treated from the central point of the universal history of mankind. This must be also the rule for fixing the epochs of Luther's life. One of the reasons why this life is not yet fully appreciated is, that it is not sufficiently understood;

and this again arises in great measure from the want of due observation of the critical points in the development of the Reformation and of the history of Europe, and of Germany in particular.

We shall divide the following condensed but complete survey into three periods. The first will be the period of preparation, extending to Luther's first publication of theses against the indulgences, 31st October 1517; the second will comprise the next eight years of preaching the gospel and gospel doctrine in its three fundamental parts; the third is that of political and theological struggles, from 1525 to his death in 1546;—preparation, progressive action, and then struggle within and without. Luther's grand character and true piety shine in both periods of his public career; but the culminating point of his active and creative agency is in the first. It is, according to our view, the year 1523 which forms the critical epoch. In 1524 the foundation of the practical realization of the principles of the Reformation was laid with triumphant success. The year 1525 began hopefully, but it ended with the preparation for a struggle, of which Luther felt at once that he never should see the end. Before the close of 1525 he gave up the cause of Germany, not in consequence of any fault committed by himself, but because he saw that his party was not prepared for the struggle with the empire, and was still less resigned to leave the matter to God, who, as Luther firmly believed to his death, would never allow his work to perish till the end of the world. But was not the end of the world coming now?

FIRST PERIOD:—*The Years of Preparation; or, the first Thirty-four Years of Luther's Life*—(1483–1517).

Martin Luther was born at Eisleben, in the county of Mansfeld, in Thuringia, on the 10th November 1483, on the eve of St Martin's Day, in the same year as Raphael, nine years after Michael Angelo, and ten after Copernicus. His father was a miner, descended from a family of poor but free peasants, and possessed forges in Mansfeld, the small profits of which enabled him to send his son to the Latin school of the place. There Martin distinguished himself so much, that his father (by that time become a member of the municipal council) intended him for the study of the law. In the meantime, Martin had often to go about as one of the poor choristers, singing and begging at the doors of charitable people at Magdeburg and at Eisenach, to the colleges of which towns he was successively sent. His remarkable appearance and serious demeanour, his fine tenor voice and musical talent, procured him the attention and afterwards the support and maternal care of a pious matron, wife of Cotta, burgomaster of Eisenach, into whose house he was taken. Already, in his eighteenth year, he surpassed all his fellow-students in knowledge of the Latin classics, and in power of composition and of eloquence. His mind took more and more a deeply religious turn; but it was not till he had been for two years studying at Eisenach that he discovered an entire Bible, having until then only known the ecclesiastical extracts from the sacred volume, and the history of Hannah and Samuel. He now determined to study Greek and Hebrew, the two original languages of the Bible. A dangerous illness brought him within the near prospect of death; but he recovered, and prosecuted his study of philosophy and law, and tried hard to gain inward peace by a pious life and the greatest strictness in all external observances. His natural cheerfulness disappeared; and after experiencing the shock of the death of one of his friends by assassination in the summer of 1505, and soon after that, being startled by a thunderbolt striking the earth by his side, he determined to give up the world and retire into the convent of the Augustinians at Erfurt—

Luther. much against the wishes and advice of his father, who, indeed, most strongly remonstrated. Luther soon experienced the uselessness of monastic life and discipline, and suffered from the coarseness of his brethren, who felt his exercises of study and meditation to be a reproach upon their own habits of gossiping and mendicancy. It was at this period that he began to study the Old Testament in Hebrew, yet continuing to fulfil scrupulously the rules of his order. "I tormented myself to death," he said at a later period, "to make my peace with God, but I was in darkness and found it not." The vicar-general of the order, Johann Von Staupitz, who had passed through the same discipline with the same result, comforted him by those remarkable words, which remained for ever engraven in Luther's heart:—"There is no true repentance but that which begins with the love of righteousness and of God. Love him then who has loved thee first!" In the struggles which followed Luther's real beginning of a new life, and in the perplexities into which Augustin's doctrine of election threw him, the book which, after the Bible, exercised the greatest and most beneficial influence upon his mind was that practical concentration of the sermons and other works of Tauler—the enlightened Dominican preacher and Christian philosopher of the middle of the fourteenth century—the *Theologia Germanica*, written by an anonymous author towards the latter part of that century, of which we shall have to speak hereafter.

When Luther regained his mental health, he took courage to be ordained priest in May 1507. Next year the Elector of Saxony nominated him professor of philosophy at the university of Wittemberg; and in 1509 he began to give, as bachelor in divinity, biblical lectures. These lectures were the awakening cause of new life in the university, and soon a great number of students from all parts of Germany gathered round Luther. Even professors came to attend his lectures and hear his preaching. The year 1511 brought an apparent interruption, but in fact only a new development of Luther's character and knowledge of the world. He was sent by his order to Rome on account of some discrepancies of opinion as to its government. His first impression of the city was that of profound admiration, soon mixed with a melancholy recollection of Scipio's Homeric exclamation on the ruins of Carthage. The tone of flippant impiety at the court and among the higher clergy of Rome, under Julius II., shocked the devout German monk. He then discovered the real state of the world in the centre of the western church; and often in after life he used to say—"I would not take 100,000 florins not to have seen Rome." Always anxious to learn, he took during his stay Hebrew lessons from a celebrated rabbi, Elias Levita; but the grand effect upon him was, that now for the first time he understood Christ and St Paul—"The just shall live by faith"—that mighty saying with which he had begun at Wittemberg his interpretation of the Bible, now sounded on his ears in the midst of Rome. He saw that external works are nothing; that the pious spirit in which any work is done or any duty fulfilled,—an humble handicraft or the preaching of sermons,—is the only thing of value in the eye of God. On his return to the university, the favour of Staupitz and the generosity of the elector procured him a present of fifty florins (ducats) to defray the expenses of his promotion to the degree of Doctor of Divinity at the end of 1512. The solemn oath he had to pronounce on that occasion (to most only a formulary without deep meaning) "to devote his whole life to study, and faithfully to expound and defend the holy Scripture," was to him the seal of his mission. He began his biblical teaching by attacking scholasticism, which at that time was called Aristotelianism. He showed that the Bible was a deeper philosophy: that, teaching the nothingness and wickedness of man as long as he is a selfish creature, it refutes and condemns all philosophical

tenets which consider man separately from his relation to Deity. All his contemporaries praised as unparalleled the clearness of his Christian doctrine, the impressive eloquence of his preaching, and the mildness and sanctity of his character. Erasmus himself exclaimed—"There is not an honest divine who does not side with Luther." Christ's self-devoted life and death—Christ crucified, was the centre of his doctrine; God's eternal love to mankind, and the sure triumph of faith, were his texts. Already, in 1516, philosophical tenets deduced from these spiritual principles were publicly defended at academical disputations, over which he presided. Luther himself preached at Dresden and other places the doctrine of justifying and vivifying faith; and then accepted, for a short time, the place of vicar-general of his order in that year. Even in the convents, spiritual, moral Christianity made its way in spite of forms and observances. When the plague came to Wittemberg, he remained when all others fled—"It is my post, and I have to finish my commentary upon the Epistle to the Galatians. Should brother Martin fail, yet the world will not fail."

Thus came the year of the Reformation, 1517. With more boldness than ever, the new pope Leo had sent, in 1516, agents through the world to sell indulgences, and the man chosen for Saxony, Tetzel the Dominican; and his band were among the most zealous preachers of this iniquity. "I would not exchange," said he in one of his harangues, "my privilege (as vender of the papal letters of absolution) against those which St Peter has in heaven; for I have saved more souls by my indulgences than the apostle by his sermons. Whatever crime one may have committed"—naming an outrage upon the person of the Virgin Mary—"let him pay well and he will receive pardon. Likewise the sins which you may be disposed to commit in future, may be atoned for beforehand." But he soon found that a spirit had been awakened among the serious minds of Germany to which such blasphemies were revolting. Luther preached and spoke out against this horrible abuse, which he said he could not believe to be sanctioned by the pope. As a great exhibition of relics, together with indulgences, was to take place on the day of All Saints in the church of Wittemberg, Luther appeared on the eve, 31st October, in the midst of the pilgrims who had flocked to the festival, and posted up at the church door the ninety-five theses against indulgences and the superstitions connected with them, in firm although guarded language. The Reformation began, like that of St John the Baptist, by the preaching of inward penitence, in opposition to penance and to absolution purchasable by gold; but Luther's preaching had the advantage that it was based upon man's redemption by Christ. Penitence was preached, as originating in the consciousness of man's unworthiness, God's mercy, and the redemption through Christ as placed before us in the gospel. The entire doctrine of these immortal Theses is summed up in the two last (94, 95), which run thus:—"The Christians are to be exhorted to make every effort to follow Christ their head through the cross, through death and hell; for it is much better they should through much tribulation enter into the kingdom of heaven, than acquire a carnal security by the consolations of a false peace." A great deed had been done that evening; a door had been opened for mankind into a course whose end is even now far from being reached. Those words—not the result of design and premeditation, but of the irresistible impulse of an honest mind brought face to face with the horrible reality of blasphemy—soon echoed through the whole world. Luther's public life had opened; the Reformation had begun.

SECOND PERIOD:—*The First Part of the Public Life of Luther, or the time of Progressive Action.*

The pilgrims had come to Wittemberg to buy indul-

Luther.

Luther. gences, and returned with the theses of Luther in their hands, and the impression of his powerful evangelical teaching in their hearts. Luther was urged on in his great work not by his friends, who were timid and terrified, but by the violence and frenzy of Tetzel and his adherents, and soon afterwards by the despotic acts of the Pope Leo X., who, having at first despised the affair as a monk's quarrel, thought he could crush it by arbitrary acts. The national mind in Germany had taken up the matter with a moral earnestness which made an impression not only upon the princes, but even upon bishops and monks. Compelled to examine the ancient history of the church, Luther soon discovered the whole tissue of fraud and imposture by which the canon law of the popes—the decretals—had been, from the ninth century downwards, foisted, advisedly and purposely, upon the Christian world. There is not one essential point in the ancient ecclesiastical history bearing upon the question of the invocation of saints, of clerical priesthood, and of episcopal and metropolitan pretensions, which his genius did not discern in its proper light. It is a remarkable fact, and must needs be considered by the philosopher of history as a proof of the spirit of God having guided Luther, that what he saw and said, at the earliest stage of historical criticism, respecting ecclesiastical forgeries and impostures, has all proved true. Soon after Luther, the Centuriatores Magdeburgici, the fathers of criticism as to ecclesiastical history, took the matter up. Of course, the Romanists denied their assertions for 200 years, and wherever they dare, they still come back to the old fables and falsehoods. But the learned discussion has been given up, step by step, reluctantly, and with a very bad grace. Whatever Luther denounced as fraud or abuse from its contradiction to the canonical worship, may be said to have been since openly or tacitly admitted to be such. But what produced the greatest effect at the time were his short popular treatises exegetical and practical. Among these are particularly remarkable his *Interpretation of the Magnificat or the Canticle of the Virgin Mary*, his deep and earnest *Exposition of the Ten Commandments*, and his *Exposition of the Lord's Prayer*, which latter soon found its way into Italy, although without Luther's name, and which has never yet been surpassed, either in genuine Christian thought or in style. Having resolved to preach in person throughout Germany, Luther appeared in the spring of 1518 in Heidelberg, where a general meeting of his Order was held. The count palatine, to whom Luther had been introduced by the elector of Saxony, received him very courteously. In order to rouse the spirit of the professors, he held a public disputation on certain theses, called by him paradoxes, by which he intended to make apparent the contrast of the external view of religion taught by the schoolmen, and the spiritual and energetic view of gospel truth based upon justifying faith. It was here that Bucer, then a Dominican monk, but soon a zealous Reformer and controversialist, and the man who, after Calvin, had among foreigners the greatest influence upon the English Reformation, heard the voice of the gospel in his own heart, and resolved to confess and preach it at the university.

"It is not the pope (said Luther in one of his disputations) who governs the church militant of Christ, but Christ himself; for it is written that 'Christ must reign till he has put all his enemies under his feet.' He evidently has not done so yet. Christ's reign, in this our world, is the reign of faith; we do not see our Head, but we have Him."

On his return to Wittemberg in May 1518, Luther wrote and published an able and moderate exposition of the theses, and sent it to some German bishops. He then proclaimed the absolute necessity of a thorough reformation of the church, which could only be effected, with the aid of God, by an earnest co-operation of the whole of Christendom. But already Rome meditated his excommunication,

uttering threats which he discussed with great courage and equanimity, saying, "God alone can reconcile with himself the fallen soul: He alone can dissolve the union of the soul with himself: blessed the man who dies under an unjust excommunication." In requesting his superior to send his very humble letter to Pope Leo, in which he declared his readiness to defend his cause, Luther added,— "Mark, I do not wish to entangle you in my own perilous affair, the consequences of which I am ready to bear alone. My cause is Christ's and God's." In the meantime, Luther was cited repeatedly to appear before the pope's tribunal at Rome. Leo, indeed, graciously promised to pay the expenses of his journey, which certainly would have been no large outlay, as none would have been required for his return. But Luther constantly declined summonses and invitations, and proposed instead one or other of the German universities as judge. This proposal was, of course, not acceptable to Rome, and therefore he was summoned before the pope's legate in Germany.

The pope's legate was Cardinal Cajetan. Luther was summoned to appear before him at Augsburg, and all princes and cities were threatened with the interdict, if they did not deliver Luther into the hands of the pope's tribunal. It was in these critical circumstances that Luther formed his acquaintance with Melancthon, who soon became his most faithful friend, and remained his zealous adherent for life. When Melancthon and all his other friends advised Luther not to go to Augsburg to be given up to the machinations of the legate, he replied,— "They have already torn my honour and my reputation, let them have my body, if it is the will of God; but my soul they shall not take." He undertook the journey, as a good monk, on foot; only provided with letters of recommendation from the elector, and accompanied by two friends, but without a safe conduct. He arrived at Augsburg on the evening of the 7th October 1518, almost exhausted by the hardships of the journey. The cardinal and his assistants employed in vain alternately threats and blandishments; scholastic arguments fell powerless, as he answered them by the Bible, and demanded to be refuted by the Word of God, to which he showed the decretals to be opposed, and therefore, according even to the declaration of the canonists, of no value. For these reasons he constantly refused to retract, as he was required to do, his two propositions,—the one that the treasure of indulgences is not composed of the merits of Christ; the other, that he who receives the sacrament must have faith in the grace offered to him. Luther left Augsburg after having addressed a firm but respectful letter to the legate; and his friends, who were sure that his life was not safe a moment longer, escorted him before daybreak out of the town on horseback. On his return to Wittemberg, he found the elector in great anxiety of mind, in consequence of an imperious missive of the cardinal legate. Luther wrote to the prince a dignified letter, saying,— "I would, in your place, answer the cardinal as he deserves for insulting an honest man without proving him to be wrong; but I do not wish to be an encumbrance to your highness; I am ready to leave your states, but I will not go to Rome." The elector refused to deliver him up to the legate, or to send him out of the states. Luther would have gone to France if deprived of his asylum in Saxony. The elector, however, having desired him to leave Wittemberg, and Luther being on the point of obeying his orders, the prince, touched by his humility and firmness, allowed him to remain and to prepare himself for a new conference. At the end of 1518, the papal bull concerning indulgences appeared, confirming the old doctrine, without any reference to the late dispute. Luther had already appealed from the pope to a general council.

The years 1519, 1520, 1521, were the time of a fierce but triumphant struggle with the hitherto irresistible power

Luther.
3. At Wittemberg, 1519-1520, he is excommunicated, and burns the pope's bull.

of Rome, soon openly supported by the empire. The two first of these years passed in public conferences and disputations at Leipzig and elsewhere, with Eck and other Romanist doctors, in which Luther was seconded by the eloquence of the ardent and acute Carlstadt, as well as by the learning and argumentative powers of Melancthon. People and princes took more and more part in the dispute, and the controversy widened from day to day. Luther openly declared that Huss was right on a great many points, and had been unjustly condemned. Wittemberg became crowded with students and inquirers, who flocked there from all sides. Luther not only continued his lectures, but wrote during this period his most important expositions and commentaries on the New Testament,—beginning with the Epistle to the Galatians (Sept. 1519), which he used to call his own epistle. During the second year (1520) the first great political crisis occurred, on occasion of the death of Maximilian, and ended fatally, in consequence of the total want of patriotic and political wisdom among the German princes. The elector of Saxony was offered by one of the most eminent and influential of his colleagues, the archbishop of Treves, to be chosen emperor; but had not the courage to accept a dignity which he supposed to require for its support a more powerful house than his own. Of all the political acts which may be designated, with Dante, *ugran vil rifiato*, this was the greatest and most to be regretted, supposing the elector to have been wise and courageous enough to give the knights and cities their proper share in the government, and patriotic enough to make the common good his own.

The German writers have called the Elector Frederic "the Wise," particularly also with regard to this question. But long before Ranke pointed out the political elements then existing for an effective improvement of the miserable German constitution, Justus Möser of Osnabruck had prophetically uttered the real truth,—“if the emperor at that time had destroyed the feudal system, this deed would have been, according to the spirit in which it was done, the grandest or the blackest in the history of the world.” Möser means that if the emperor had embraced the Reformed faith, and placed himself at the head of the lower nobility and the cities, united in one body as the lower house of a German parliament, this act would have saved Germany. But we ought to go further, and say, to expect such a revolution from a Spanish king was simply absurd. Frederic alone could, and probably would, have been led into that course, just because he had nothing to rely upon except the German nation, then more numerous and powerful than it ever has been since. The so-called capitulations of the empire, which were accepted by Charles, contained not the slightest guarantee against religious encroachments on the side of Rome.

Persecutions aimed at the life of Luther began very early. Being one day accosted by a stranger, who concealed a pistol in his sleeve, and asked him, “Why do you walk thus alone?” the intrepid hero answered, “Because I am on the side of God, who is my strength and my shield.” The unknown person turned pale and slunk away. The pope's emissaries in Germany openly demanded the death of Luther. Flattery and threats were used alternately to that end. Luther said, “I do not wish for a cardinal's hat: let them allow the way of salvation to be open to Christians, and I shall be satisfied. All their threats do not frighten me, and all their promises do not seduce me.” When Francis of Sickingen, the most powerful and spirited of the knights of the empire, and the brave and enlightened Ulrich von Hütten and others, offered aid, and said, “force of arms was required to drive out the devil,” Luther answered in those immortal words: “By the Word the world has been conquered; by the Word the church has been saved; by the Word too, she will be restored: I do not despise your offers, but I will not lean upon any one but Christ.”

Luther's writings of this period are the finest productions of his pen. His book *On Good Works* is the best exposition of the doctrine of justification by faith. Melancthon says, in reference to this treatise,—“No writer ever came nearer St Paul than Luther has done.” In the same year (1520) he published that grand address to the nobles of the German nation, *On the Reformation of Christendom*, which may be considered as the finest specimen of the political and patriotic wisdom of a Christian. There he shows the reality and supreme dignity of the universal priesthood of Christians, and at the same time demands a thorough reform of the social system of Germany and Italy, beginning with the abrogation of the usurped power of the pope, while he calls for a national system of education as the foundation of a better order of things. This address, published on the 26th June 1520, electrified the nation. It was this appeal which first moved the patriotic and sainted spirit of Ulrich Zwingli, the Swiss Reformer, who tried in vain to dissuade Rome from endeavouring to crush Luther by a bull of excommunication. It was too late. The great step had been decided upon.

Luther meanwhile continued his course of preaching and lecturing at Wittemberg, where nearly 2000 students were assembled. He published at this time his *Treatise on the Mass*, in which he applied to the sacraments the pervading doctrine of faith, proving from Scripture that every sacrament is dead without faith in God's word and promises. But his most striking work of this period is that on the *Babylonian Captivity of the Church* (October 1520), in which he boldly took the offensive against Rome, attacking papacy in its principles. It is remarkable that in this treatise he speaks of the baptism of infants, who necessarily are incapable of faith, as of an apparent contradiction, which, however, might be defended. Man is to have faith in the baptismal vow (to be ratified later, after the necessary instruction), and therefore he must not allow himself to be bound by any other vow, and must consider the work of his vocation, whatever it be, as equally sacred with that of priest or monk. Till the Christian church is organized upon that principle, the Christian people live in Babylonian captivity. In order to please some of his friends, and show to the world that he was not intractable, he addressed a letter to Leo X., and inclosed a treatise, *On the Liberty of the Christian*. He pities the pope for having been thrown like Daniel into the midst of wolves, and predicts that the Roman court (*Curia Romana*) will fall because she hates reform, and that the world will be obliged, sooner or later, to apply to her the words of the prophet—“We would have healed Babylon, but she is not healed: forsake her, and let us go every one unto his own country” (Jerem. li. 9). “O most holy father, (he adds) do not listen to those flattering syrens around you!”

The treatise itself is a sublime and succinct exposition of the two truths, that by faith the soul acquires all that Christ has, and becomes free through Him; but then it begins to serve His brethren voluntarily from thankfulness to God. The pope's bull arrived in due time; but found the German nation deaf to its curses, and armed against its arguments. It was called Dr Eck's bull; and Luther raised, on the 4th November, his voice of thunder against it in a short treatise *Against the Bull of Antichrist*; and, on the 17th of the same month, he drew up, before a notary and five witnesses, a solemn protest, in which he appealed to a general council. After this manifesto, he invited the Christian bull burnt before the church door, and said,—“Now the serious work begins; I have begun it in the name of God—it will be brought to an end by his might.” But where was the power to resist the pope, if the emperor supported the pope's cause? And, indeed, he had promised this support to the pontifical minister soon after his coronation

Luther.

He is excommunicated.

Burns the pope's bull.

Luther. at Aix-la-Chapelle on the 22d October. He declared, however, at the same time, that he must act with every possible regard towards the elector; and this prince had courage enough to propose, as the only just measure, to grant to Luther a safe conduct, and place him before learned, pious, and impartial judges. Erasmus, whom he invited, in order to learn his opinion, said,—“There was no doubt that the more virtuous and attached to the gospel any man was, the more he was found to incline towards Luther, who had been condemned only by two universities, and by them had not been confuted.”

4. At the
diet of
Worms,
April 1521.

The emperor agreed at last to the proposal of the elector Frederic, and convened a diet at Worms for 6th January 1521, where the two questions of religion and of a reform in the constitution of the empire were to be treated. Luther, though in a suffering state of health, resolved immediately to appear when summoned. “If the emperor calls, it is God’s call,—I must go: if I am too weak to go in good health, I shall have myself carried thither sick. They will not have my blood, after which they thirst, unless it is God’s will. Two things I cannot do,—shrink from the call nor retract my opinions.” The nuncio and his party, on their side, moved heaven and earth to procure Luther’s condemnation, and threatened the Germans with extermination, saying,—“We shall excite the one to fight against the other, that all may perish in their own blood,”—a threat which the papists have carried out to the best of their power during 200 years. The emperor permitted the nuncio to appear officially in the diet, and to try to convince the princes of the empire there assembled. Alexander tried in vain to communicate to the assembly his theological hatred, or to obtain that Luther should be condemned as one judged by the pope, his books burnt and his adherents persecuted. The impression produced by his powerful harangue was only transitory: even princes who hated Luther personally, would not allow his person and writings and the general cause of reform to be confounded, and all crushed together. The abuses and exactions of Rome were too crying. A committee, appointed by the diet, presented a list of 101 grievances of the German nation against Rome. This startled the emperor, who, instead of ordering Luther’s books to be burned, issued only a provisional order that they should be delivered to the magistrates. When Luther heard of the measures preparing against him, he composed one of his most admirable treatises,—*The Exposition of the Magnificat, or the Canticle of the Virgin Mary*. He soon learnt what he was expected to retract. “If that is meant, I remain where I am: if the emperor will call me to have me put to death, I shall go.” The emperor summoned him, indeed, on the 6th March 1521, to appear before him, and granted him at last a safe conduct, on which all his friends insisted. Luther, in spite of all warnings, set out with the imperial herald on the 2d April. Everywhere on the road he saw the imperial edict against his book posted up, but witnessed also the hearty sympathies of the nation. At Erfurt the herald gave way to the universal request, and, against his instructions, consented to Luther’s preaching a sermon,—none the less remarkable for not containing a single word about himself. On the 16th Luther entered the imperial city amidst an immense concourse of people. On his approach to Worms, the elector’s chancellor entreated him, in the name of his master, not to enter a town where his death was decided. The answer which Luther returned was simply this:—“Tell your master, that if there were as many devils at Worms as tiles on its roofs, I would enter.” When surrounded by his friends on the morning of the 17th, on which day he was to appear before the august assembly, he said,—“Christ is to me what the head of the gorgon was to Perseus: I must hold it up against the devil’s attack.” When the hour approached, he fell upon his knees, and

uttered in great agony a prayer such as can only be pronounced by a man filled with the spirit of Him who prayed at Gethsemane. Friends took down his words; and the authentic document has been published by the great historian of the Reformation. He rose from prayer and followed the herald. Before the throne he was asked two questions,—Whether he acknowledged the works before him to have been written by himself? and whether he would retract what he had said in them? Luther requested to be told the titles of the books, and then, addressing the emperor, acknowledged them as his; as to the second, he asked for time to reflect, as he might otherwise confound his own opinions with the declarations of the Word of God, and either say too much, or deny Christ and say too little, incurring thus the penalty which Christ had denounced,—“Whosoever shall deny me before men, him will I also deny before my Father which is in heaven.” The emperor, struck by this very measured answer, which some mistook for hesitation, after a short consultation, granted a day’s delay for the answer, which was to be by word of mouth. Luther’s resolution was taken: he only desired to convince his friends, as well as his enemies, that he did not act with precipitation at so decisive a moment. The next day he employed in prayer and meditation, making a solemn vow upon the volume of Scripture to remain faithful to the gospel, should he have to seal his confession with his blood. Luther’s address to the emperor has been preserved, and is a masterpiece of eloquence as well as of courage. Confining his answer to the first point, he said, that “nobody could expect him to retract indiscriminately all he had written in those books, since even his enemies admitted that they contained much that was good and conformable to Scripture. But I have besides,” he continued, “laid open the almost incredible corruptions of popery, and given utterance to complaints almost universal. By retracting what I have said on this score, should I not fortify rank tyranny, and open a still wider door to enormous impieties? Nor can I recal what, in my controversial writings, I may have expressed with too great harshness against the supporters of popery, my opponents, lest I should give them encouragement to oppress Christian people still more. I can only say with Christ,—‘If I have spoken evil, bear witness of the evil’ (John xviii. 23). I thank God I see how that the gospel is in our days, as it was before, the occasion of doubt and discord. This is the doctrine of the Word of God,—‘I am not come to send peace but a sword’ (Matt. x. 34). May this new reign not begin, and still less continue, under pernicious auspices. The Pharaohs of Egypt, the kings of Babylon and of Israel, never worked more effectually for their own ruin than when they thought to strengthen their power. I speak thus boldly, not because I think that such great princes want my advice, but because I will fulfil my duty towards Germany, as she has a right to expect from her children.” The emperor, probably in order to confound the poor monk, who having been kept standing so long in the midst of such an assembly, and in a suffocating heat, was almost exhausted in body, ordered him to repeat the discourse in Latin. His friends told him he might excuse himself, but he rallied boldly, and pronounced his speech in Latin with the same composure and energy as at first; and the reiterated question, Whether he would retract? Luther replied,—“I cannot submit my faith either to the pope or to councils, for it is clear that they have often erred and contradicted themselves. I will retract nothing, unless convicted by the very passages of the Word of God which I have quoted.” And then, looking up to the august assembly before him, he concluded, saying,—“Here I take my stand: I cannot do otherwise: so help me God. Amen!” The courage of Luther made a deep impression even upon the emperor, who exclaimed,—“Forsooth, the

Luther.

Luther.

monk speaks with intrepidity, and with a confident spirit." The chancellor of the empire said,—“The emperor and the state will see what steps to take against an obstinate heretic.” All his friends trembled at this undisguised declaration. Luther repeated, “So help me God! I can retract nothing.” Upon this he was dismissed, then recalled, and again asked whether he would retract a part of what he had written. “I have no other answer to make,” was his reply. The Italians and Spaniards were amazed. Luther was told the diet would come to a decision the next day. When returning to his inn, he quieted the anxious multitude with a few words, who, seeing the Spaniards and Italians of the emperor’s household follow him with imprecations and threats, exclaimed loudly, in the apprehension that he was about to be conducted to prison.

The elector and other princes now saw it was their duty to protect such a man, and sent their ministers to assure him of their support. The next day the emperor declared, “he could not allow that a single monk should disturb the peace of the church, and he was resolved to let him depart, under condition of creating no trouble; but to proceed against his adherents as against heretics who are under excommunication, and interdict them by all means in his power; and he demanded of the estates of the empire to conduct themselves as faithful Christians.” This address, the suggestion of the Italian and Spanish party, created great commotion. The most violent members of that party demanded of the emperor that Luther should be burnt, and his ashes thrown into the Rhine; and it is now proved that, towards the end of his life, Charles reproached himself bitterly for not having thus sacrificed his word for the good of the church. But the great majority of the German party, even Luther’s personal enemies, rejected such a proposition with horror, as unworthy of the good faith of Germans. Some said openly they had a child, misled by foreigners, for an emperor. The emperor decided at last that three days should be given to Luther to reconsider what he had said. The theologians began to try their skill upon him. “Give up the Bible as the last appeal; you allow all heresies have come from the Bible.” Luther reproached them for their unbelief, and added: “The pope is not judge in the things that belong to the Word of God; every Christian man must see and understand himself how he is to live and to die.” Two more days were granted, without producing any other result than Luther’s declaration,—“I am ready to renounce the safe conduct, to deliver my life and body into the hands of the emperor; but the Word of God, never! I am also ready to accept a council, but one which shall judge only after the Scripture.” “What remedy can you then name?” asked the venerable archbishop of Treves. “Only that indicated by Gamaliel,” replied Luther; “if this counsel or this work be of men, it will come to nought; but if it be of God, ye cannot overthrow it, lest haply ye be found even to fight against God” (Acts v. 38, 39).

Frederic the Wise knew well that Luther’s life was no longer safe anywhere at this moment. Charles pronounced an edict of condemnation, couched in the severest terms. Luther was placed under the ban of the empire. After twenty-one days his safe conduct would expire, and all persons be forbidden to feed or to give him shelter, and enjoined to deliver him to the emperor or to place him in safe keeping till the imperial orders should arrive; all his adherents were to be seized, and their goods confiscated; his books burnt; and the authors of all other books and prints obnoxious to the pope and the church were to be taken and punished. Whoever should violate this edict should incur the ban of the empire.

This Draconian edict had been passed by the majority; the friends of Luther, foreseeing the issue, had left Worms previously. Such was the condign punishment that befell

the Germans for having chosen as their emperor the most powerful foreign prince of Europe, brought up among the most bigoted of nations. Under these circumstances, Frederic did what he could. In the forest of Thuringia, not far from Eisenach, Luther (who was not in the secret) was stopped by armed knights, set upon a horse, and conducted to the fortified castle above Eisenach—the Wartburg. Here the dress of a knight was ready for him. He was desired to consider himself as a prisoner, and to let his beard grow. None of his friends, even at Wittemberg, knew what had become of him. He had disappeared; the majority believed he had been kidnapped by his powerful enemies. Such was the indignation of the people at this supposed treachery, that the princes opposed to the Reformation, and even the pope’s agents, began to be alarmed, and took pains to convince the people that Luther had not met with ill usage.

Luther remained ten months at the Wartburg; and it was here that he began his greatest work, the translation of the Bible from the original Hebrew and Greek text. Although suffering much in health from the confinement, which he modified latterly by excursions in the woods around the castle, he soon began also to compose new works, and obtained the necessary books through Melancthon, to whom he in time made known that he was safe.

It is a most astonishing fact, highly characteristic both of Luther and of the German nation, that, though for nearly four years, the true doctrine of the gospel had been preached through Germany, and the Romish rites and ceremonies exhibited as abuses, that yet not one single word or portion of these ceremonies had been changed. Luther consciously believed, what may be called the latent conviction of his countrymen, that inward truth will necessarily correct outward errors, and mould for itself fitting forms of expression. “The Spirit of God,” he often said, “must first have regenerated minds, imbued with true gospel doctrine; then the new forms will result naturally from that Spirit.” But it was clearly an unnatural and highly dangerous state of things, that the outward acts of worship should be utterly at variance with the belief of the worshippers; and Luther saw that if he would not take the matter in hand, others were certain to do so; the people themselves might proceed to precipitate acts. Luther felt this, and so strongly, that he broke silence; and in September published a declaration against monkish vows, in the form of theses, addressed to the bishops and deacons of Wittemberg. The audacious attempt of the Cardinal-Archbishop of Mayence, Albert of Brandenburg, to renew at Halle the sale of indulgences, called forth Luther’s philippic (1st November) *Against the new Idol of Halle*.

This attack frightened even the court of the elector of Saxony, who was at that time rather of opinion that Luther could do nothing better than to cause himself to be forgotten. “I cannot allow him to attack my brother elector, and to disturb the public peace.” Luther’s greatness of soul had elevated the minds of the princes for the moment; they had saved his life, but they wished now to live in peace, such as they had before. Luther was indignant. “Do they think I suffered a defeat at Worms? It was a brilliant victory: so many against me, and not one to gainsay the truth!” To Spalatin, the chaplain and adviser of the elector, he thus writes: “How, the elector will not allow me to write! and I, for my part, will not allow him to disallow my writing. I will rather destroy you, and the prince, and every creature! Having resisted the pope, should I not resist his agents?” At the request of Melancthon, he laid aside the treatise he had prepared, but wrote to the cardinal archbishop:—“The God who raised such a fire out of the spark kindled by the words of a poor mendicant monk lives still; doubt it not. He will resist a cardinal of Mayence, even though

Luther.

5. At the Wartburg, March 1521 to Feb. 1522.

Luther. supported by four emperors; for above all He lives to lay low the high cedar, and humble the proud Pharaohs. Put down the idol within a fortnight, or I shall attack you publicly."

The cardinal was frightened by the sternness of the man of God, and had the meanness to play the hypocrite. He thanked Luther by letter for his "Christian and brotherly reproof," promising, "with the help of God, to live henceforth as a pious bishop and Christian prince." Luther, however, could not credit the sincerity of this declaration:—"This man, scarcely capable to rule over a small parish, will stand in the way of salvation as long as he does not throw off the mask of a cardinal and the pomp of a bishop."

The fact was, the cardinal elector wanted money. He had had to pay 26,000 ducats to Rome for his pallium, and the half of that sum he had charged upon the venders of indulgences in his ecclesiastical province; he himself having to spend all his princely income on his court.

6. Appears at Wittemberg, Mar. 1522. During these nearly ten months of seclusion, Luther's health suffered greatly, and subjected him to visions and hallucinations, in which he believed he saw the devil in form. His absence from his congregation, his students, and his friends and books at Wittemberg, weighed heavily upon him. Still, he held out patiently till events occurred which called upon the Reformer no longer to absent himself. He reappeared, without previous notice, among his friends at Wittemberg, whom he found in great commotion. Thirteen monks of Luther's own convent had left it on the ground of religious conviction, with the approbation of Melancthon, who also countenanced the general demand for the abrogation of the mass. "What we are to celebrate," said he, "in the communion, is a sign of the grace given us through Christ, but differing from symbols invented by man by its inward power of rendering the heart certain of the will of God." This is the simplest and truest form of Luther's own view of the Lord's Supper, when he looked on it not scholastically. There is a reality in Christ's sacrifice for us; indeed, it is the reality of our destiny that we remember it, as He has bidden His disciples to do: it has therefore naturally an inward force, not an imaginary effect, like looking on a cross and similar outward forms. What calamities would the world have been spared if this view, in its profound simplicity and depth, had not been dressed up in formularies partaking of that very scholasticism which the Reformation was to abolish! The prior of the convent discontinued from that time low masses. It was high time, indeed, that this central point of Christian worship should be taken in hand by the Reformers; for at Zwickau, in Saxony, an enthusiast, named Stork, arose, who pretended to have a commission from the archangel Gabriel to reform and govern the church and the world, and who was supported in this by a fanatic named Thomas Munzer. When they appeared at Wittemberg announcing their visions, even Melancthon was startled, and especially hesitated as to the question of pædo-baptism. Carlstadt, Luther's disciple and friend, advocated the most revolutionary changes. He broke down the images, preached against learning and study, and exhorted his hearers to go home and gain their bread by digging the ground. Luther did not hesitate a moment to condemn the whole movement as a delusion for men who gloried in their own wisdom, which could only cause a triumph to the enemies of reform. At an interview which he had with Munzer and Horst, they said they could prove to him that they had the Spirit; for they would tell him what now passed in his mind. Luther challenged them to the proof. "You think in your own heart that we are right," Luther exclaimed.—"Get thee behind me, Satan," and dismissed them. "They were quite right," he said to his friends afterwards; "that thought crossed my mind as to some of their assertions. A spirit evidently was in them, but what could it be but the evil one?" Here we see the difference

between Luther and Melancthon. Luther was not startled from his solid judgment as Melancthon had been by this movement; and Melancthon, in after years, was a more violent antagonist of anabaptism than Luther.

It was on the 3d of March 1522 that Luther left for ever his asylum, and plunged into the midst of struggles very different in their character from those which he had hitherto so victoriously overcome. Before arriving at Wittemberg, he wrote a remarkable letter to the elector:—"You wish to know what to do in the present troublesome circumstances. Do nothing. As for myself, let the command of the emperor be executed in town and country. Do not resist if they come to seize and kill me; only let the doors remain open for the preaching of the Word of God." One of the editors of Luther's works observes on the margin,—"This is a marvellous writing of the third and last Elijah." The elector was touched by Luther's magnanimity. "I will take up his defence at the diet; only let him explain his reasons for having returned to Wittemberg, and say he did so without my orders." Luther complied, adding,—"I can bear your highness' disfavour. I have done my duty towards those whom God has intrusted to me." And, indeed, he made it his first duty to preach almost daily the gospel of peace to his flock. "No violence!" he exclaimed, "against the superstitious or unbelieving. Let him who believes draw near, and let him who does not believe stand aloof. Nobody is to be constrained; liberty is essential to faith and all that belongs to it. . . . You have acted in faith," he said, "but do not forget charity, and the wisdom which mothers show in the care of their children. Let the reform of the mass be undertaken with earnest prayer. The power of the word is irresistible: the idols of Athens fell not by force, but before the mighty words of the apostle." This evangelical meekness of the man who had braved pope and emperor, and knew not fear, acted with divine power upon all minds. The agitation and sedition disappeared. The pretended prophets dispersed, or were silenced in public debate.

On the 21st September 1522 the translation of the New Testament appeared in 2 volumes folio, which sold at about a ducat and a half. The translation of the Old Testament was commenced in the same year. Thousands of copies were read with indescribable delight by the people; who had now access to the words of Him whom Luther had preached to them as the author of our salvation, in their mother tongue, in a purity and clearness unknown before, and never surpassed since. By choosing the Franconian dialect in use in the imperial chancery, Luther made himself intelligible both to those whose vernacular dialect was High German or Low German. Luther translated faithfully but vernacularly, with a native grace which up to this day makes his Bible the standard of the German language. It is Luther's genius applied to the Bible which has preserved the only unity which is, in our days, remaining to the German nation,—that of language, literature, and thought. There is no similar instance in the known history of the world of a single man achieving such a work. His prophetic mind foresaw that the Scripture would pervade the living languages and tongues all over the earth—a process going on still with more activity than ever.

Meanwhile the vanity and presumption of Henry VIII. induced him to publish a book against Luther, in which he heaped upon Luther every opprobrious epithet; even called in question his honesty and sincerity, and declared him worthy to be burned. His *Defence of the Seven Sacraments* merely recapitulates the old scholastic tradition without the slightest understanding of the Bible or of the evangelical doctrine. Henry's ambassador declared to the pope, in presenting the book, that the king was now ready to use the sword against Luther's adherents, after having

Luther. refuted the errors of Luther himself. Luther, after having read the book, declared, contrary to the desire of the elector and of his other friends, that he must answer it. "Look," he writes, "what weapons are used against me: fire and the fury of those stupid Thomists. Let them burn me: alive I shall be the enemy of popery; burnt I shall be its ruin. Everywhere they will find me in their way, like a bear or a lion." In the answer itself he pays the king in his own coin. After having taken the crown from his head and beaten him like any other controversial writer, he exclaims,—"I cry gospel, gospel! Christ, Christ! and they cease not to answer,—Usages, usages! ordinances, ordinances! fathers, fathers! The apostle St Paul annihilates with a thunderstorm from heaven all these fooleries of Henry." The king wrote to the elector and the dukes of Saxony, exhorting them to extirpate this heresy, as being the revival of that of Wycliffe. Their answer referred Henry to the future council. The cause of the Reformation suffered nothing from Henry's attacks and the invectives of his courtiers. The movement against the sacerdotal and monkish vows extended through the whole of Germany—affecting equally priests and laymen. Zealous preachers of the gospel rose from all ranks. Noble and pious women came forward to declare their faith. Luther's activity was unparalleled. In 1522 he published 130 treatises, and 83 in the following year.

The whole national literature of Germany became Protestant; and it is certainly a remarkable fact, that, in spite of the Reformation having since lost almost one-half of Germany, its literature, as well as its historical learning and philology, still remains Protestant. All the free cities, which were the cradle of the fine arts as well as of the wealth of the country, declared in favour of the Reformation. In Saxony there was, as Luther had proposed and demanded, perfect liberty of conscience: the Romish bishops had their preachers as well as the Reformers.

Luther's heart expanded in the consciousness of the Reformers' success such as he had never hoped to see. But he shrunk from the idea that this work should be regarded as his, and that he should have the honour of it. "My true disciples," he said, "do not believe in Luther, but in Jesus Christ; I myself care nothing about Luther. What is it to me whether he be a saint or a miscreant? It is not him I preach, but Christ. If the devil can, let him have Christ; but if Christ remains ours, we also shall subsist."

When Leo X. died in this year (1522), Adrian, the Flemish tutor of Charles V., his successor, a single-minded professor, could not (as Jarus tells us) at first conceive how people could find a difficulty in the matter of indulgences, which he had explained so well in his lectures, till a cardinal remarked to him, that the unbelieving people had no faith in indulgences whatsoever, and that some of those who believed in Christ, thought that exactly for that reason they did not want them. "The church must reform," said he, "but step by step." "Yes," said Luther, "putting some centuries between every step." Nobody wanted his reforms less than the Romans; and Adrian exclaimed at last,—"How unfortunate is the position of the popes, who are not even free to do good."

In November 1522 the diet assembled at Nuremberg on account of an impending war with the Turks. While the nuncio and the bishops demanded Luther's death, the churches of the imperial free city resounded with the doctrine of the gospel; monks being amongst the most zealous preachers. What a change from the state of things at Worms in April 1521! The municipal council of the free city declared that if those preachers were to be seized by force, they would instantly set them free by force. The legate was obliged to abandon his plan of arresting them in the pope's name, as the diet declared itself incompetent to do so. Adrian's sincere avowal of the horrible abuses of Rome

confirmed the people in the belief that Luther and the gospel were right, and made his threatening brief addressed to the elector, whom he declared worthy of death and eternal damnation, appear as ridiculous as it was arrogant. Luther and all his friends, whose advice the elector asked at this critical moment, declared that he ought not to fight for the gospel, seeing that the people, without whose consent he could not declare war, would not in the spirit of faith declare for such a measure. But other princes were frightened, because they had no faith whatever, except in superior strength and power of pope and emperor. "Let them take care," said Luther, "if they persecute the gospel, there will be a rebellion and civil war, and the princes will be in danger of losing their dominions. They wish to destroy me, but I wish to save them. Christ lives and reigns; and I shall live and reign with Him." Indeed, a bloody persecution began in many parts of Germany and in the Netherlands. Four Augustinian monks of Antwerp were the first martyrs; they were burnt on the 1st July 1523. Their blood called forth a rich harvest of new witnesses in Brussels and elsewhere.

When the successor of Adrian VI., Clement VII. (Julius de Medici), sent in 1524 the celebrated legate Campeggi to Nuremberg, he intended, according to usage, on passing through Augsburg, to give the people the papal benediction; but finding that the ceremony called forth public derision, the legate entered Nuremberg as much *incognito* as Luther had entered Worms two years before. The German princes asked what had become of the 101 grievances of the German nation, to which Rome never had deigned to return an answer. Campeggi declared the document to have been considered at Rome merely as a private pamphlet; on which the diet, in great indignation, insisted upon the necessity of an universal council, and proceeded to annul the edict of Worms; declaring, however, in their communication to the pope, that "it should be conformed to *as much as possible*;" which, with respect to many princes and cities, meant *not at all*. Finally, it was resolved that a diet, to be held at Spire in November, was to decide on religious differences. Many states which had hitherto kept aloof,—the landgrave of Brandenburg (not the elector, a strong papist) at the head,—declared immediately for the reform, and against the seven sacraments, the abuses of the mass, the worship of saints and supremacy of the pope. "That is a good move," said Luther. "Frederic must lose his electoral hat," cried the Roman agent, "and France and England must interfere." A catholic league was formed, by Bavarian and other bishops, at Ratisbon under Campeggi's direction and presidency. But the princes were still afraid of the universally spreading national movement. Charles threw his power into the balance, and declared that not the German nation, but the emperor alone, had a right to demand a council, and the pope alone had the right to grant it. His designated successor, his brother Ferdinand, began the bloody work of persecution in the hereditary states of Austria immediately after the congress of the league at Ratisbon. At Passau in Bavaria, and at Buda in Hungary, the faggots were lighted. The dukes of Bavaria followed the same impulse.

Meanwhile, began at Wittemberg the unhappy dispute about the mode in which the consecration affected the elements in the celebration of the communion enjoined by Christ. Luther as yet had not taken up that doctrinal scholastic opinion, which afterwards produced the fatal schism. In opposing Carlstadt's view, he combated not so much the later Swiss exposition as Carlstadt's false interpretation of the words, "This is my body," which was, that Christ, in pronouncing them, had pointed to his own body, which soon would die. He admitted soon afterwards, in reference to that exposition, in 1520, that he was very near thinking the Swiss interpretation the reasonable view of the case, but that he had rejected the notion as a "tempta-

Luther.

and the diet
at Nurem-
berg, Nov.
1522.

The Catho-
lic league.

Luther. tion," the words of the text seeming to him not to allow of that interpretation.

8. Luther the practical reformer.

But in the same manner as this dispute was a prelude to the fatal sacramental disputes with Zwingli and Calvin, Luther's defeat in the attempt to detach the congregation of a small town (Orlamunde, near Jena) from Carlstadt, who introduced iconoclastic and violent proceedings, proved an index of the critical state of public feeling. Luther felt the urgent necessity of applying the principles of the gospel to Christian worship and to the constitutions of the church. But, on the first point, he wished changes to be introduced gradually, and rather as a purification of the existing forms, than by an abrogation. While as to the second, he felt that it was not his immediate vocation, and he thought he must leave the work to the princes, and content himself with preaching to them the leading evangelical principles. This, of course, was not the view of the real friends of the Reformation, nor was it consistent with Luther's usual profound sagacity, but must be regarded as a remnant of the effect produced by his monkish scholastic education brought into accordance with Christianity. His more practical, and perhaps impatient friends wanted to see the pagan condition of the world, with its social relations, changed into a Christian state of things, as an earnest and pledge of the reality of the gospel preaching. Still, for some time longer, Luther and the popular feeling marched peaceably together, and he remained the national as well as the theological leader. It was at this time that he directed a powerful address to the municipal councils of the German towns, in order to exhort them to establish everywhere Christian schools, as well elementary as learned. "Oh, my dear Germans (he exclaims), the divine word is now in abundance offered to you: God knocks at your door; open it to him! Forget not the poor youth. Look how the ancient Jewish, Greek, and Roman world lost the Word of God, and perished. The strength of a town does not consist in its towers and buildings, but in counting a great number of learned, serious, honest, well-educated citizens. Do not fancy Hebrew and Greek to be unnecessary. These languages are the sheath which cover the sword of the Spirit. The ignorance of the original Scriptures was an impediment to the progress of the Waldenses, whose doctrine is perfectly pure. How could I have combated and overthrown pope and sophists, even having the true faith, if I had not possessed the languages? You must find libraries for learned books,—not only the fathers, but also the pagan writers; the fine arts, law, history, medicine, must be represented in such collections." These expressions prove that from the very beginning and in the very person of Luther, the Reformation was connected with scholarship—with philology in its most extended sense, and equally with the highest aspirations of the fine arts.

Gives impulse to education.

Here we must conclude this first glorious period of Luther's life, which, taken altogether, has no parallel since the days of the apostle Paul. But the problem to be solved was not to be solved by Luther and by Germany: the progressive, vital element of reformation passed from Germany to Switzerland, and through Switzerland to France, Holland, England, and Scotland. Before he descended into the grave and Germany into thralldom, Luther saved (as much as was in him) his country and the world, by maintaining the fundamental principles of the Reformation against Melancthon's pusillanimity: but three Protestant princes and the free cities were the leaders; the confession was the work of Melancthon, but the deed of the laity of the nation. The German Reformation was made by a scholastically trained monk, seconded by professors; the Swiss Reformation was the work of a free citizen, an honest Christian, trained by the classics of antiquity, and nursed in true, hard-won, civil liberty. That was the providential saving of the world. Luther's work was

continued, preserved, advanced by the work of the Swiss and French Reformers. The monk and the Semitic element began; the citizens and the Japhetic element finished. If the one destroyed Judaism, the other converted paganism, then most powerful, both as idolatry and as irreligious learning. But as long as Luther lived he did not lose his supremacy, and he deserved to keep it. His mind was universal, and therefore catholic in the proper sense of the word.

Luther.

THIRD PERIOD:—*Luther's Life from 1525 to 1546; or the Period of Stagnation.*

The first year after Luther's return to Wittenberg was a glorious period: the true halcyon days of the Reform and of Luther's personal history. In the second period of his life, the epic was changed into tragedy; for the Anabaptist tumult arose, and the war of the peasants broke out in the Black Forest in July 1524.

The Anabaptist movement of Thomas Munzer was the 1. War of movement of Carlstadt mixed up with wild enthusiasm, the peasants. ignorance, rebellion, and imposture. Luther's doctrinal opposition to it was constant and consistent; but it would have been more effectual if Luther had not involved himself as a schoolman in an indissoluble difficulty. He was safe in defending pædo-baptism; but that could be done without ascribing to it the power of individual regeneration: an opinion from which the greatest part of Christendom has most decisively declared its dissent all over the globe. He was equally justified in maintaining the word of the gospel: "Whoever believes, and is baptized, shall be saved;" but he ought not to have forgotten that this is a juxtaposition of two things, of which the one can only be of value as a consequence of the first. This brings the question back to a solemn profession and vow before the Christian congregation of him who, having been instructed in Christ's saving faith, finds himself ready and compelled to make that solemn promise, which St Peter calls (1st Peter iii., 21),—"the promise (or vow) of a good conscience." Munzer and all the other so-called apostles of the Spirit attacked Luther as a mere worldly man who had sold himself to the princes. They abolished chaunting and all ceremonies, and committed acts of violence against churches and convents. Luther said to Munzer,—“The spirit who moves thee must be an evil one, for it brings forth nothing but pillage of convents and churches; the greatest robbers on the earth could do no more.” While combating them by preaching and writing, he advised, however, the elector to let them preach freely. “The Word of God itself must come forward and contend with them. If their spirit is the true one, Munzer will fear our constraint; if ours is the true one, he will not fear their violence. Let the spirits meet with all might, and fight each other. Perhaps some will be seduced; well, there is no battle without wounds; but he that fights faithfully will be crowned. But if they have recourse to the sword, then defend your own subjects, and order the Anabaptists to leave the country.”

It was indeed a wonderful faith that produced such toleration in these times, and it had a wonderful result;—the elector's states remained undisturbed. Munzer fled into Switzerland.

It was otherwise with the war of the peasants. We have already observed that the Reformation did not originate the rebellion of the peasants, but found it prepared. The first coalitions of the peasants against the intolerable rapacity and cruelty of the feudal aristocracy had begun before the close of the fifteenth century; then they broke out along the Upper Rhine, in Alsace, and the palatinate, in 1503; consequently 18 years before the beginning of Luther's Reformation. No doubt Luther's preaching, in the spirit of the gospel, against all the revolting injustice and oppression of the conscience of Chris-

Luther.

tian men, had kept back that movement for a time; but Munzer carried the spirit of rebellion and fanaticism among the peasants and part of the citizens of the countries of the Upper Rhine. The fact was, that all the oppressed inclined towards Luther, and the oppressors, most of whom were the sovereigns, bishops, and abbots, towards the pope. The struggle which now began was therefore between the reforming and the papist party, and it was easily to be foreseen that Luther would soon be dragged into it. Indeed, the revolutionary movement was already, in January 1525, extending from the Black Forest to Thuringia and Saxony, the very heart of Luther's sphere of action. The peasants had proclaimed twelve articles, of half biblical half political character. In the introduction to these articles they protest against the imputation of wanting anything but the gospel applied to the social body. They declare their desire to uphold its injunctions—peace, patience, and union. There is no doubt that many of them were sincere in their professions. At all events, neither the gospel nor its true preachers and followers were the revolutionists, but the wild, selfish, passionate enthusiasts among them and their leaders. Like the Puritans in the following century, the peasants say they raise their voice to God who saved the people of Israel; and they believe that God can save them as well from their powerful oppressors as he did the Israelites from the hand of Pharaoh.

Luther's address to the lords.

As to what they demanded in their twelve articles, all impartial historians declare that on the whole their demands were just; and all of them are now the law of Germany. As to the influence of the Reformation, the very words of Scripture brought forward this time by the peasants, prove clearly that Luther's preaching of the gospel and of truth had not acted upon the movement as an incentive but as a corrective. It was Luther himself who now, in the critical moment, brought the Word of God to speak out against the insurrection, as being in itself an act of unchristian self-defence, although he acknowledged their case to be very hard, and their cause, on the whole, a just one. Luther's position was grand; he spoke as the arbiter between lord and peasant; in the name of Christ exhorting both parties to peace, and as a good citizen and patriot giving them advice equally practical and Christian. He first speaks thus in substance to the lords:—"I might now make common cause with the peasants against you, who impute this insurrection to the gospel and to my teaching; whereas I have never ceased to enjoin obedience to authority, even to one so tyrannical and intolerable as yours. But I will not envenom the wound; therefore, my lords, whether friendly or hostile to me, do not despise either the advice of a poor man, or this sedition; not that you ought to fear the insurgents, but fear God the Lord, who is incensed against you. He may punish you and turn every stone into a peasant, and then neither your cuirasses nor your strength would save you. Put then bounds to your exactions—pause in your hard tyranny—consider them as intoxicated—and treat them with kindness, that God may not kindle a fire throughout Germany, which none will be able to extinguish. What you may perhaps lose will be made good to you a hundred-fold by peace. Some of the twelve articles of the peasants are so equitable that they dishonour you before God and the world; they cover the princes with shame, as the 109th Psalm says. I should have yet graver things to tell you respecting the government of Germany, and I have addressed you in this cause in my book to the German nobility. But you have considered my words as wind, and therefore all these demands come now upon you. You must not refuse their demand as to choosing pastors who preach to them the gospel; the government has only to see that insurrection and rebellion be not preached; but there must be perfect liberty to preach the true gospel as well as the false. The remaining articles, which regard the social state of

the peasant, are equally just. Government is not established for its own interest, nor to make the people subservient to caprice and evil passions, but for the interest of the people. Your exactions are intolerable; you take away from the peasant the fruit of his labour, in order to spend his money upon your finery and luxury. So much for you."

Luther.

"Now, as regards you, my dear friends, the peasants. You want the free preaching of the gospel to be secured to you. God will assist your just cause if you follow up your work with conscience and justice. In that case you are sure to triumph in the end. Those of you who may fall in the struggle will be saved. But if you act otherwise you are lost, soul and body, even if you have success, and defeat the princes and lords. Do not believe the false prophets who have come among you, even if they invoke the holy name of the gospel. They will call me a hypocrite, but I do not mind that. I wish to save the pious and honest men among you. I fear God and none else. Do you fear Him also, and use not His name in vain, that He may not punish you. Does not the Word of God say: 'He who takes up the sword, shall perish by the sword;' and 'Let every soul be subject to the higher powers.' You must not take justice into your own hands; that is also the prescription of the natural law. Do you not see that you put yourself in the wrong by rebellion? The government takes away part of what is yours, but you take away all in destroying principle. Fix your eye on Christ at Gethsemane rebuking St Peter for using the sword although in the defence of his master; and on Christ on the cross praying for his persecutors. And has not his kingdom triumphed? Why have pope and emperor not been able to put me down? Why has the gospel spread the more the greater the effort they made to hinder and destroy it? Because I have never had recourse to force, but preached obedience even towards those who persecuted me, depending exclusively on God. But whatever you do, do not try to cover your enterprise by the cloak of the gospel and the name of Christ. If war there must be, it will be a war of pagans, for Christians use other weapons: their general suffered the cross, and their triumph is humility; that is their chivalry. Pray, my dear friends, stop and consider before you proceed further. Your quotations from the Bible do not prove your case."

After having thus spoken out boldly and fearlessly to each party, Luther concludes with a touching expostulation to both. The substance of his address is in these words:—"You see you are both in the wrong, and are drawing the divine punishments upon you and upon your common country, Germany. My advice would be that arbitrators should be chosen, some from the nobility, and some from the towns. You both have to give up something; let the matter be settled equitably by human law."

This certainly was the voice of the true prophet of the age, if ever there was any. It was not heard. The lords showed little disposition towards concessions, and what they did offer came too late, when the bloody struggle had already begun. The peasants, excited by Munzer, exceeded, on their side, all bounds, and Luther felt himself obliged, when the stream of rebellion and destruction rolled on to Thuringia and Saxony, to speak out most strongly against them. The princes leagued together (for the empire, of course, did nothing, Charles having full employment in Spain), and the peasants were routed everywhere. Fifty thousand of their party were slain or butchered by wholesale executions. Among this number there were many of the quietest and most moderate people made victims in the general slaughter, because they were known or suspected to be friends of the Reformation and of Luther, which, indeed all the citizens and peasants of Germany were at that time.

None felt more deeply this misery, and what it involved

Luther. In its effects on the cause of the gospel in Germany; and he never recovered the shock. He thus unburdens his soul at the close of this fatal year, which crushed for centuries the rights and hopes of the peasants and labourers, and weakened the towns and cities, the seats of all that was best in the national life:—"The spirit of these tyrants is powerless—cowardly—estranged from every honest thought. They deserve to be the slaves of the people. But by the grace of Christ I am sufficiently revenged by the contempt I have for them, and for Satan their god. And in the next year he said, "I fear Germany is lost; it cannot be otherwise, for they will employ nothing but the sword."

2 General
disunity:
Luther's
struggles,
1525.

In all this Luther stands higher than ever, but as a sufferer. He sees the work in Germany is lost for this time. He submits, and is supported by his faith. So he is consoled when he sees how Ferdinand of Austria and the Duke of Bavaria imprison and slaughter Christians on account of the gospel, and that not only the pope and the emperor are leagued together against the Reformation, but also the king of France, besides the king of England. All the powers of the world are against him: Germany is doomed to perish, but the word and the work of God cannot perish. Even the sad results of a general visitation of the churches which he undertook throughout the states of the elector did not shake his faith. He sees how ignorant and savage all these wars and revolts have rendered even the Protestant congregations; but he says the spirit of God will not forsake them. The elector Frederic, Luther's timid but honest supporter, had descended into the tomb on the 5th May 1525, confessing on his deathbed his firm belief in Christ as his only saviour. His successor, John, known by the well-deserved name, John the Constant, followed in his footsteps, and was a firm friend to Luther.

But the Romish league also gained friends in the north of Germany. Duke George of Saxony had, in July of this year, concluded at Dessau an alliance against the Reformation with Albert of Brandenburg, archbishop of Mainz and Magdeburg, and with the dukes of Brunswick, and proved himself in earnest by causing two citizens of Leipzig to be beheaded for having the writings of Luther in their houses. At the same time, Charles declared from Spain his intention to hold a diet at Augsburg, evidently in order to crush the Reformation by means of the Catholic league acting in the name of the empire. His victory at Pavia made him more than ever the master of Germany. Finally, the remains of the party of Munzer declared they would take the life of Luther as a traitor.

His mar-
riage.

It was under such auspices that Luther decided at last to take a wife, as he had long advised his friends among the priests and monks to do. They had often reminded him of his profession, and of the duty of himself setting an example to prove his sincerity. His father himself urged him continually to marry. All around him was now in a stationary, if not a retrograde state. The university of Wittemberg had suffered much during the late troubles, and it was generally believed that the new elector did not mean to support it. Luther's warm and loving heart opened the more readily to the contemplation of matrimonial union with Catherina von Bora, a lady 24 years of age, of a noble Saxon family, in 1523, who had left her convent, together with eight other sisters, in order to worship Christ without the oppression of endless ceremonies, which gave neither light to the mind nor peace to the soul. Since that time they had lived together in utter retirement, forming a free Christian community. Pious citizens at Torgau were their protectors, and by them they were presented to Luther in the convent of the Augustinians. Soon followed, as we have seen, the great regenerative movement of the Christian worship; and Luther appeared, on the 9th October 1524, before the congregation in the simple habit of a secular priest. Luther soon remained alone in the convent; all the monks had left it. At the end of the year he sent

the key to the elector, who, however, desired him to continue to inhabit it. In the meantime, Luther had observed and witnessed the Christian faith and life of Catherina von Bora, and on the 11th of June he married her, in the presence of Lucas Cranach, the celebrated painter, and of another friend, as witnesses. Catherina von Bora had no dowry, and Luther lived on his appointment as professor; he would never take money for any of his books, but only some copies for presents. His marriage was a happy one, and was blessed with six children. Luther was a tender husband and the most loving of fathers.

Luther.

The princes who were friendly to the Reformation gradually gained more courage; the Elector John of Saxony established the principle in his states that all rites should be abrogated which were contrary to the Scriptures, and that the masses for the dead be abolished at once. The young Landgrave Philippe of Hesse gained over the son of the furious Duke George to the cause of the Reformation. Albert, Duke of Prussia, had established it at Königsberg, as hereditary duke, abolishing the vows of the Order, whose master he had been, saying:—"There is only one Order, and that is Christendom." At the request of the pope, Charles placed Albert under interdict as an apostate monk. The evangelical princes found in all these circumstances a still stronger motive to act at Augsburg as allies in the cause of the evangelical party; and when the diet opened in December 1525, they spoke out boldly:—"It is violence which brought on the war of the peasants. If you will by violence tear the truth of God out of the hearts of those who believe, you will draw greater dangers and evils upon you." The Romanist party was startled. "The cause of the holy faith" was adjourned to the next diet at Spire. The landgrave and the elector made a formal alliance in February 1526, at Torgau.

3. Progress
of practical
Reformation.

Alliance to
support the
Reformation,
1526.

Luther being consulted as to his opinion, felt helpless. "You have no faith; you put not your trust in God; leave all to Him." The landgrave, the real head of the evangelical alliance, perceived that Luther's advice was not practical—that Luther forsook the duty of self-defence and the obligation to do one's duty according to the dictates of reason, in religious matters as well as in other political questions. But the alliance found no new friends. Germany showed all her misery by the meanness of her princes and the absence of any great national body to oppose the league formed by the pope, the emperor, and the Romanists, throughout Europe. The archbishop of Treves preferred a pension from Charles to the defence of the national cause. The evangelically-disposed palatine desired to avoid getting into trouble on that account. The imperial city of Frankfurt, thus surrounded by open enemies and timid friends, declined to accede to the alliance. There was more national feeling and courage in the Anglo-Saxon north of Germany. The princes of Brunswick, Luxemburg, Mecklenburg, Anhalt, and Mansfeld, assembled at Magdeburg, and made a solemn and heroic declaration of their resolution to pledge their estates, lives, states, and subjects, for the maintenance of the holy Word of God, relying on Almighty God, as whose instruments they would act." The town of Magdeburg (which then had about three times as many inhabitants as now) and Duke Albert of Prussia adhered to the alliance. The league doubled its efforts. Charles, strong and rendered safe by the peace of Madrid concluded with Francis, sent word from Seville in March 1526, through the Romish Duke Henry of Brunswick, that he would soon come himself to crush the heresy. Luther saw the dangers crowding around him: his advice was,—"We are threatened with war; let us force our enemies to keep the peace, conquered by the Spirit of God, before whose throne we must now combat with the arms of prayer; that is the first work to be done."

Towards the end of 1525, Luther had resolved to answer a book which had been written against him in the previous au-

Luther.
4. Erasmus
against
Luther.

tumn by Erasmus, under the catching title "*On Free Will*." Erasmus was in his heart rather a sceptic: he would in his earlier days have professed openly the cause of the gospel, and defended it with his superior erudition and knowledge, had he believed in its success; but neither the Swiss nor the German Reformation gave him that certainty, and thus, at last, he gave way to King Henry and others, who urged him to attack Luther. No controversy has been less generally understood than this; but it may also be said that it might have been carried on not only with less malice by Erasmus, but also with more speculative skill by Luther. The antagonism is essentially the same as that of Augustine and Pelagius, or that between the Jansenists and Jesuits: a better speculative method and a deeper philosophy of the mind have since shown how the scholastic method never could solve that most important as well as most difficult problem. We have no hesitation in saying that the result of dialectic metaphysics is no other than that Luther was perfectly right and Erasmus totally wrong, in this dispute; but it was hopeless from the beginning. Erasmus defined free will as the faculty of man to decide for himself, be it for good or evil. Consequently, to deny his thesis in this sense would have been to deny the moral responsibility of man. But Luther's ideas respecting moral free will were as dissonant from this terminology as St Paul's reasoning on faith, from the use of that word in the sense in which St James employs or rather attacks it. In regard to Luther's terms and fundamental ideas, we have touched upon them in speaking of the influence of Tauler and of the *Theologia Germanica* upon his mind, when he was disturbed by what appeared to him the dreadful consequences of the doctrine of grace and election. That theology of the German school of the fourteenth century rested upon a simpler, because deeper basis than that of Augustine, and, more lately, of Calvin and Pascal. There is in man, as a creature, the power of self-will; this is not only evil as such, but the root of all evil, and sin. The power of deciding whether or not to commit an action is therefore nothing but the power of measuring and contrasting selfish principles, neither of which being good, can produce good actions. There is no power against this selfishness of the creature but the divine principle. This, the old German school maintained, is equally an inherent element in man,—not as a creature, but as God's image,—and the instrument of the infinite, divine Spirit, which is essentially goodness, and love of what is good and true as such, apart from any reference to ourselves. To follow up this view successfully, it is evidently necessary not to establish an absolute separation between the divine principle in itself (in God, the infinite) and in man; and this was not clearly understood by Augustine (whose influence upon Luther was paramount, in consequence of his earliest impressions), and still less skilfully used by Luther. The absurdities to which, as each of the combatants proved of his opponent, the consistent following up of an antagonistic principle conducts, are shown by Kant to be the necessary organic consequence of our reasoning with finite notions upon the infinite; his antinomies of free will and necessity are those of Erasmus and Luther, divested of theological and dogmatic terms. But the same philosophy (and Kant himself, in his *Moral Philosophy*, and his *Philosophy of Religion*), shows that Christianity and the analysis of conscience and moral consciousness of ourselves teach equally what Luther maintained against Erasmus. The rationalism of Erasmus and of the Jesuits is condemned by this philosophy; and whatever may be thought of the philosophical demonstration (which we think capable of great simplification), St John and St Paul are certainly irreconcilable with it. "Erasmus ignores God," said Luther, "and that word is more powerful than any scholastic argument." Erasmus felt himself crushed by Luther's strong hits, against which his eloquence availed him nothing. "The victory must re-

Luther's
reply.

main," Luther said, "with stammering truth, not with lying eloquence;" and he concluded thus: "Who ever possessed so much science and eloquence, and such art in speaking and in writing? I have nothing of all this; but I glory in one thing—I am a Christian. May God raise you in the knowledge of the gospel infinitely above me, so that you may surpass me as much in this respect as you do already in all others." Erasmus henceforth lost all measure and philosophical equanimity, never having sought truth for its own sake.

Luther.

The diet of Spires, which was to put an end to Luther's Reformation, opened on June 25, 1526. Ferdinand indeed republished, on the 3d of August, the decree of Seville, enjoining strict execution of the edict of Worms; but, in the meantime, Clement the VII. having quarrelled with Charles, and Ferdinand being called to Hungary in order to maintain against Soliman and other competitors the crowns of Hungary and Bohemia, left to him by King Louis after the battle of Mohacz, Charles commissioned the famous Captain Frundsberg (the same who had good-naturedly accosted Luther at Worms, and who was devoted to the evangelical cause) to enlist an army in Germany against the pope, and thousands hastened to join his ranks in consequence. And thus the Reformation was saved this time, and a proposition presented by the cities was accepted, "that until a council met, every governor should, within his own states, act according to his conscience." Within a year, if not a universal, at least a national council was to meet. In consequence, the Reformation had time to consolidate itself from 1526 to 1529. The man of Germany at that time among the princes was the Landgrave Philip of Hesse, and he was enlightened by a citizen. James Sturm, the deputy of Strasburg at the diet of Spire, had convinced him that the basis of the true evangelical church was the acknowledgment of the self-government of the church by synods composed of representatives of the whole Christian people. Thus the first Protestant constitution—that agreed upon in Hesse—was essentially that which has proved since to be the most universal and the most powerful. For that constitution is neither Lutheran nor Anglican, but synodal Christianity, which has converted and is now converting and conquering the world. The constitution acknowledged the episcopal element, but not episcopal rule,—sovereignty being invested in the people of God. We admit (say the articles) no word but that of our sovereign pastor. Bishops and deacons are to be elected by the Christian people; bishops are to be consecrated by the imposition of hands of three bishops; and deacons may be instituted by imposition of the hands of the elders. The general synod is to be held annually, consisting of the pastor of each parish and of pious men elected from the midst of each church, or rather congregation, or from single churches. Three men are to be elected yearly to exercise the right of visitation. This was soon found to be an inconvenient form; six superintendents (episcopi) for life were substituted. This board of superintendents became afterwards an oligarchy, and at last a mere instrument of the state—the consequence of the disruption of Germany and the paralysis of all national institutions. Luther had professed already, in 1523 and in 1524, principles entirely identical with those established in 1826 in Hesse. But there his action ceased; he left to the princes what they had no mind to carry out; and what could a people do cut up into 400 sovereignties? Never, however, did Luther acknowledge Cesaropapism or Erastianism, as a principle and as a right. He considered the rights of the Christian people as a sacred trust, provisionally deposited in the hands of their representatives. "Where (he asked) are the people to form the synods? I cannot find them." This was a political calamity or mistake, but it was not a treason to the rights of the Christian people. Still more did Luther

to 1529.

Luther. abhor the rapacity of the nobility and of the courtiers to possess themselves of the spoils of the church. It was Melancthon's influence which facilitated the despotic system, and hampered the thorough reform of the forms of worship. Luther withdrew from a sphere which was not his. He composed, in 1529, the small and great Catechisms, of which the former has maintained its place as a guide of popular doctrine up to this day; but when measures of persecution were proposed, he raised his voice against them. He wrote, in 1528, *False Teachers are not to be put to Death; it suffices to Remove them*. While Luther preached this doctrine, the most bloody persecution went on in the estates of the elector of Brandenburg (where the electress professed courageously the principles of the gospel), in Bavaria, and, above all, in the hereditary states of Austria. In February 1528 the impetuous landgrave was on the point of committing a rash act, in consequence of a forged document which had been shown to him, purporting to be a secret convention to assassinate Luther and Melancthon, and crush the evangelical princes. Philip infected the elector with his apprehensions, and violent measures of persecution were to be resorted to, when Luther and Melancthon both gave, as their solemn advice, this verdict,—“The attack must not come from our side, and the guilt of bloodshedding must not come upon us. Let the emperor know of this odious conspiracy.” The elector, however, assembled his troops; but the forgery was soon discovered when the document was communicated to the Romanist princes. The attitude taken by the Protestant princes had, however, the effect of making the archbishop of Mainz renounce, in 1528, the spiritual jurisdiction he had hitherto exercised over Saxony and Hesse. But among the public at large, all believed in the existence of a secret plot against the evangelical party.

6. The second diet of Spire, 1529. Under these auspices was opened the celebrated diet of Spire in 1529. The emperor, who, in the meantime, had taken Rome, and annihilated the ambitious plans of Clement VII., now took again to his natural part. German credulity and good nature had served his turn. Now that he felt himself master of the field, he spoke as a Spanish despot; the elector and landgrave were forbidden to celebrate divine worship in their hotels, as they had done in 1527, after the use of a church had been denied them. The imperial commissioners desired to return to the edict of Worms of 1521. The solemn act of toleration voted by the diet of 1527 was abrogated by an arbitrary act of the emperor alone, contrary to the constitution of the empire. Luther, the proscribed, was not present; but Melancthon, who had accompanied the princes, reported to him what passed. The majority of the diet passed at last, on 7th April, a resolution, that where the edict of Worms could not be executed without fear of revolution, no further reform would be allowed. This evidently was nothing but the intended forerunner of the restoration of Popery.

The protestation and Protestants' isin. It was against this iniquitous decree that the elector, the landgrave, the margrave of Brandenburg, the prince of Anhalt, and the chancellor of Luneburg, together with the dignitaries of the towns, laid down that solemn protestation from which originates the name of “Protestants.” “The diet has overstepped its authority,” they said; “our acquired right is, that the decree of 1526, unanimously adopted, do remain in force until a council can be convened. Up to this time the decree has maintained the peace since, and we protest against its abrogation.” Of thirty-five free cities, fourteen stood out firmly, when Ferdinand threatened them with the loss of their privileges. Strasburg, which was at the head of the protesting cities, was placed by this most arbitrary act under the interdict. To the princes Ferdinand declared there remained nothing for them but to submit; and he closed the diet without awaiting the resolutions of the

Luther. evangelical princes, who had passed, as was the constitutional custom, into an adjoining apartment in order to deliberate. The princes then drew up their declaration, and caused it to be read to the diet, which had remained sitting when Ferdinand rose with the imperial commissioners.

The celebrated Protest of the 15th April 1529, is one of the finest and noblest documents of Christian history, displaying an apostolic faith in Christ and Scripture, and a dignified adherence to national law as far as constitutional liberties are concerned. The protesting princes and cities claim as their right, as Germans, what they consider a sacred duty as Christians,—freely to preach the Word of God and the message of salvation, that all who will hear it may join the community of the believers. This great act was, besides, an earnest of true evangelical union; for it was well known that most of the cities inclined more towards Zwingle's than towards Luther's view of the sacrament. And this union was not a negative but a positive one; it was founded on the faith, energetically and sincerely professed by Cœcolampadius, as the organ of the Swiss Reformed churches, that, “with the visible symbols invisible grace is given and received.”

If one considers this great act impartially, it is impossible not to see that neither Luther nor Melancthon were the real leaders of the time. Already in 1526, Luther had so little real comprehension of what ought to be done, or was now doing in Germany, to preserve the gospel from destruction, that he wrote to a friend on the very same day that the decree of that first diet at Spire was published:—“The diet is going on in the German way,—they drink and they gamble; for the rest, nothing is done there.” He shows no sympathy for the first attempt made in Hesse at self-government of the church; still less did he see the importance of the great act now achieved at Spire by the combined courage and Christian common sense of some few princes, and all cities which could act freely. It was evident that Charles was now, after the peace of Cambray, perfect master of Germany; so far, at least, as to make it impossible that Germany should become a Protestant nation, and that the protesting princes and cities had seen the necessity of strengthening that alliance of which they had just laid the foundation. Luther dissuaded the elector from sending deputies to the meeting agreed upon to be held at Schmalcalden. “In silence and rest will be your strength,” was his vote. The elector sent deputies in order to hinder that anything should be decided. Luther was proud of this success. “Christ the Lord will deliver us without the landgrave, and even against the landgrave,” was his saying. This apparent blindness and perversion of mind in Luther at this time admits a twofold explanation. The first is Luther's loyal and sound policy. He abhorred rebellion, and shuddered from a civil war, even if it should be unavoidable as self-defence. He besides saw clearly that the princes, divided among themselves as they were, could do nothing against the emperor without the best part of the nation, represented by the cities; and that here, too, there was want of mutual trust and good-will, and above all of unity. But this key opens only the outer door to Luther's mind. To understand him, when he seems proof against reason, and reasoning even his own, it is necessary to consider his unshaken faith, and that he partook of the quietism of his German master, Tauler, and the *Theologia Germanica*. “Suffer God to do his work in you and about you,” was the motto of that school. But the scholastic training also had its influence as to his view of the Zwinglian Reformation, and it centred in Luther's sacramentalism. This point requires a more ample consideration.

It must be confessed that there was a theological scruple at the bottom of Luther's opposition to a vigorous Protestant alliance and national attitude, which was sure not to bring on war, but to prevent it by making the execution of

Luther.
7. The key to Luther's controversy with the Zwinglians as to the sacraments.

the aggressive plans of the pope and emperors impossible. This betrays itself, first, in an uneasiness about Zwingli's rising influence in Germany; and, second as a doctrinal idiosyncrasy respecting the sacrament of the communion. Philip of Hesse instantly saw through this, and said,—“I see they are against the alliance on account of the Zwinglians; well, let us see whether we cannot make these theological differences disappear.” It is well known that all the efforts made to effect a union between the Zwinglian and Lutheran parties, from the conference at Marburg, in 1529, to the end of Luther's life, were fruitless; and it is impossible not to admit that the fault was Luther's, and that he became aware of that only on his deathbed. As we are thus arrived at the deepest tragedy of Luther's life and of the history of Protestantism, and as we must endeavour, within the narrow limits of an article, to establish historical truth on these important points, as far as it is indispensable for a true and philosophical view of Luther's life, we think it unnecessary to prove that there were no mean passions at work in Luther's mind; but we will say shortly that it was the great tragedy of the Christian mind during more than one thousand years to which Luther paid now his tribute.

When Luther was raised above himself by the great problem before him, in that glorious period of action, from 1518 to 1524, he considered the sacraments altogether as a part of the services of the church, and a secondary point, in comparison with the right view of faith, or the inward Christianity which implies necessarily an unselfish, believing, and thankful mind. Having come to the conviction that there was no inherent virtue in the elements abstractedly from the communion, it was indifferent to him how the spirituality of the action and the real presence, even the transubstantiation, might be reconciled with that faith. But when he felt himself called upon at a later period to form a theory respecting the doctrine of the sacrament, he could never get free from the action of those two theological schools, the mystical German and the Latin scholastic, in the point where they combined. Thus, to his end Luther firmly believed that the act of the priest pronouncing the words, “This is my body,” produced a change in the elements, making them the body and blood of Christ, which he interpreted, however, as meaning the whole creature of Christ. Now, nothing was ever more historically erroneous. It has been shown elsewhere by the writer of this article, through an uninterrupted chain of documentary evidence of the very liturgies, from the second to the sixth century, that the recital of the words of the institution was nothing but the historical introduction to a prayer of blessing for the communicants. This prayer invoked the Spirit of God to descend upon the assembled worshipping congregation. The first step which unconsciously led to misunderstandings, was, that the blessing of God was also called down upon the elements in order to make the food prepared for the faithful the body and blood of Christ. The consecration, in other words, was not the recital of the words of institution, but a prayer, down to the time of Basilus, extemporized, or at least freely spoken, and always ending with the Lord's prayer. It is a tragical complication that the question as to what the elements became,—a question unknown and even unintelligible during the first five centuries,—should have entangled the mighty evangelical mind of the Reformer, whose appointed work was the destruction of the Romish system of delusion founded upon a total perversion of the fundamental Christian notions respecting sacrifice, priest, and atonement. It was this fatal ignorance of the oblation of the sound and organic, as well as the morbid Christian worship development, which blinded Luther to such a degree as not only to put a simply absurd interpretation upon the words of the institution, but to base the question of Christian communion between evangelical Christians upon the

same, instead of allowing it to be freely discussed as a scholastic question. When staking all upon what he called a literal interpretation of the words, “This is my body,” he ought to have acknowledged, at least, that others might as well take objection, if not to the absurdity of such a meaning, at least to the liberty which Luther claimed for himself at the same time, of making the body stand for the whole life contained in it, not to speak of the objection founded upon the words of institution as we find them in Luke and St Paul.

After these general observations, our historical relation of what remains to be told of Luther's life may be very short.

The first event was the conference of Marburg. The undaunted spirit of the landgrave, and the heroic self-devoted spirit of Zwingli, who accepted the invitation at the evident risk of his life, brought about that celebrated meeting on the first five days of October 1527. The frank and liberal declarations and concessions of the Swiss Reformers soon cleared away all shadows of difference and dissent, except that about the sacrament. In the half public disputation of the 2d of October, Zwingli embarrassed Luther by observing, that if the body of Christ was in the bread and wine, in any other than a spiritual sense, he must be present in a given place, by the very nature of matter, and not above matter, in heaven. Luther parried that stroke by saying,—“I do not mind its contradicting nature, provided it do not contradict the faith.” Still less could he disentangle himself from the words of Christ in the 6th chapter of St John, which Zwingli declared he could not discard, as it was a text and a clear one. Not more satisfactory was Luther's appeal to the fathers. The discussions of the four following days, however, resulted in recognising the point of difference, but reducing its expression to the mildest form, and placing it in the background, as compared with the full statement of the points on which both parties were united. Tears of joy filled all eyes; and Zwingli, with Œcolampadius and Bucer, returned satisfied, although the promised alliance between Germany and Switzerland was not concluded owing to Luther's reluctance. Zwingli had triumphed; his views became naturalized in Germany, where hitherto they were little known, and the dreadful words of Luther,—“Submit yourselves; believe as we do, or you cannot be acknowledged as Christians,” were forgotten. But no sooner had Luther returned to Wittenberg than he modified the articles in an exclusive sense, which necessarily shocked and alienated the Reformed party.

The issue of the conference at Marburg was a sad prelude to the great and decisive diet to be held at Augsburg in 1530,—the diet immortalized by the first confession of evangelical Christendom. All the appearances were changed; the elector, who, as well as the landgrave, went there in great pomp, was received by the emperor in the most flattering manner. All was to be peace and concord in Germany. Behind the scenes we see the emperor quieting his brother Ferdinand, the head of the Romish and fanatical party, who protested against such encouragement to heresy. He writes to him:—“I shall go on negotiating without concluding anything; fear nothing if I even should conclude; there will never be pretexts wanting to you to chastise the rebels, and you will find people enough too happy to offer you their power as a means of vengeance.”

Charles was an Austrian tyrant and a Spanish bigot, and a great politician of the Italian school, which has procured him, even from historians of our time, the name of a great man. The only reason why he did not now follow the advice of the cardinal legate and the Spaniards, and of his own brother Ferdinand, was simply that he thought the good Germans would do the work of destruction themselves, and

Luther. that in the mean time he would have in them a check upon the pope. But in his own mind he was ready to sacrifice to the bigoted party all the constitutional rights of the diet, as he had sacrificed that wonderful republic of Florence to the Medici family at the request of the holy father, who (said Charles) could not demand anything wrong: of course, least of all in a case which regarded his own house!

The diet of Augsburg is the bright point in the life of the Elector John the Constant, as the conference of Marburg is in that of the landgrave. When the emperor's ministers, who preceded him at Augsburg, announced to the elector the emperor's intentions, in order to intimidate him, he said,—“If the emperor intends to stop the preaching of the gospel, I shall immediately betake myself to my home.” Luther had been left at Coburg, the nearest safe place for the proscribed, and was consulted daily. He told the elector he had no right to say so; “the emperor was his master, and Augsburg was an imperial town.” Grand and heroic, although erroneous, advice of the man whose life must have been the first sacrifice of a policy which the elector meant to resist! The lawyers, however, were here also in fault; their Byzantine notions of imperial rights made them timid in the application of the principles of the German constitution. The Protestant princes had a clear constitutional right to resist the emperor, standing upon the resolutions and the edict of Worms, and the solemn declaration of Spire. Melancthon himself thought they might maintain the right of preaching the gospel, only abstaining from any controversial point. But undoubtedly those were right who advised the elector to remain. As to the chief practical point, Chancellor Bruck confirmed the elector in his resolution not to allow the preaching of the gospel to be interdicted to him and his friends. As to alliances and leagues, the elector said,—“I have formed no secret alliances; but I will show those I have entered into if the others will show theirs.” In the meantime, Melancthon had by the middle of April prepared the articles of the confession with their defence, the so-called apology. Luther sat all the time in his solitary castle. “It is my Sinai,” he said, “where I lift up my hands to pray, as Moses did during the battle.” He worked at the Psalms and the prophets (he translated here Jeremiah and Ezekiel), and dedicated his hours of recreation to a popular edition of what was called *Æsop's Fables*, as Socrates did in his prison. “I am making a Zion out of this Sinai, and build there three tents, viz., one for the psalms, one for the prophets, one for *Æsop*,” a truly German saying, which the historian of the Reformation ought not to have censured. How could Luther endure his solitude in that tremendous crisis which, as far as the affairs of Germany were concerned, he saw in darker colours than anybody, unless he had some recreation of this kind. But besides, his object was to place his *Æsop* (which contains many compositions of his own) in the hands of the people, instead of a common popular book of the time, of the same title, of the lowest and most immoral description. It was also in this solitude that he wrote that admirable letter to his son Hans, with the description of the garden of wonders. While here he received the news of his father's death, which affected him deeply, so that his health began to give way, and his hallucinations, or waking dreams, recommenced. The news of the league between Charles V., Francis I., the Pope, and Venice, roused at times the political spirit which was in him. “I do not believe a word,” he said, “as to the reality of such a league. *Monsieur par ma foy!* (Francis) cannot forget the battle of Pavia; *Monsieur in nomine domini* (Clement VIII.) is, first, a Welsh (Italian), which is bad enough; secondly, a Florentine, which is worse; thirdly, a bastard, a child of the devil; and, fourthly, he will never forget the indignity of the plundering of Rome. The Venetians, finally, are Venetians, and they have reasons enough to hate the

VOL. XIII.

posterity of Maximilian. Poor Charles, he is like a sheep among wolves; God will save him!” There is the sound politician and the loyal German, hoping against hope, and trusting his prince's promises as long as he breathes! He wrote letters full of comfort to the elector, and at the same time addressed one of his most powerful writings to the clergy assembled in the diet at Augsburg, in which he shows them the absurdity of their system, and the unchristian spirit of their claims. The address concludes with the prophetic verse,—

“Pestis eram vivus; moriens ero mors tua Papa!”

[“O Pope, thy plague I was in life; in death I shall be thy destruction.”]

On the 4th of June Gattinara, the chancellor of Charles, died—an Italian, who most earnestly wished a real reform of the church; and the advocates of persecution got the upper hand. On the side of the Protestants, the Swiss party began to suspect Melancthon, and complained of the use of Latin chants and surplices in Saxony; while, on his side, Melancthon detested what he called the seditious principles and worldly reasoning of the Swiss. Soon afterwards, we see him ready to give up some of the essential points to the emperor, who, on his approach to Augsburg, said:—“What do the electors want? I shall do what I like.” Well had he learned in Spain the lessons of tyranny which Cardinal Ximenes knew so well to apply under Philip II. But he prayed four hours every day, so that the people said (as he scarcely ever spoke),—“He talks more with God than with men.” When in the conference with the Protestant princes, he demanded of them to cease from their present mode of worship, they declared that their conscience did not allow them to do so, and the margrave of Brandenburg, bowing down towards Charles, and putting his hands upon his neck, cried out,—“Rather than allow myself to be deprived of the Word of the Lord, and rather than deny my God, I will have my head cut off at your majesty's feet.” This startled the Spaniard. “Dear prince,” he exclaimed, “not the head, not the head!” Imprisonment will do, he thought all the while, and those incautious words betray that thought. This was all his Sacred Cæsarean Majesty deigned to utter during the diet. Great was his wrath when the princes declared indignantly that they would not consent to follow the procession of the host at the festivals of *Corpus Domini*. Why not worship a wafer which the priest has made God? And why not show this respect to the emperor and cardinal? asked Ferdinand. “We can and we will worship none but God,” they unanimously declared. Their worship went on, and the vast church of the Franciscans was always crowded; an eloquent Zwinglian preached powerful sermons from the book of Joshua about the people of Israel in the face of Canaan. Charles was furious; an insidious compromise was proposed; the emperor would name preachers who should simply read the epistles and gospel of the day, and the ordinary prayer of confession before the mass. The pusillanimity of Melancthon, and the legal opinions of some of the lawyers of the Protestant princes as to the emperor's power in an imperial town, overcame the repugnance of the elector. All the Protestant preachers left the place in dismay. The whole town was in consternation. “Our Lord God,” exclaimed the elector, “has received order to hold his tongue at the diet!” Luther all the while had been quiet, waiting in patience. But this was too much for him. “This is the first step,” he said, “to the demand that we give up our faith. We have to fight against the gates of hell.” “Keep up your courage,” he wrote to Melancthon, “for you are the ambassadors of a great King.” The elector and his theologians thought it justifiable that, in virtue of his office as grand marshal of the empire, he should bear before the emperor the sword of state, when the latter attended the mass of the

Luther.

Luther.

Holy Ghost at the opening of the diet, on which occasion an Italian archbishop preached a most fanatical and insulting sermon against the Germans, as being worse enemies of God than the Turks. In the imperial opening speech, Charles spoke of the lamentable dissensions which encroached upon the imperial majesty, and must produce sedition and murder. The Protestants were required to present their confession. The elector signed it first; four other princes and two cities after him, without any observation; the landgrave of Hesse, however, did not sign it without saying he did not agree as to the doctrine of the communion. The article says,—“That the body and blood of Christ are verily present, and are administered in the Lord's Supper to those who partake of it [and we disapprove those who teach otherwise].” The words in brackets were left out in later editions made during Luther's lifetime. On this occasion the princes took really the lead, and the whole was done as a great national, not as a sacerdotal work, in spite of poor Melancthon's scruples. This good man was indeed entirely out of his sphere, and lost his time, and committed the cause of Protestantism, by trying to bring about a compromise where there was no possibility of an honest understanding. In the mean time, Luther was left in complete and cruel ignorance of all that was going on; and when at last the letters of Melancthon arrived, they were full of fears and sad misgivings. During all this anxious time, Luther sought and found his comfort in constant prayer and occupation with the Word of God. “Where is Christ's church, if it is not with us? Faith alone is required. I will rather fall with Christ than stand with Cæsar.” Luther reprimanded Melancthon sharply for his pusillanimity, and some of his letters to him are addressed—“To Master Philip Kleinmuth” (pusillanimous).

After many tergiversations, the Protestants obtained their just demand; the confession, drawn up by Melancthon and approved by Luther, was read in public sitting on the 25th June 1530. A great day, worthy of the most glorious days of the apostolic times. Luther was not present; he was dead as a public man. But he lived in God, and for his faith and country. Nothing could damp his spirits. “I also have my diet,” he said; “and what lively discussions!”—referring playfully to the rooks which swarmed round his tower.

The emperor ordered the confession to be read in Latin. “No,” said the elector; “we are Germans, and on German ground. I hope, therefore, your majesty will allow us to speak German.” The emperor gave way, recollecting for the nonce he was in Germany, and that the Germans had a language of their own, and the strange fancy of using it even in theological affairs. When the chancellor of the elector had read the first part of that grand confession, which expounds the principles of the Reformation, and, in particular, the doctrine of justification by faith,—“that faith which is not the mere knowledge of a historical fact, but that which believes not only the history, but also the effect of that history upon the mind,”—there was an indescribable effect visibly produced upon the assembly. The opponents felt that there was a reality before them which they had never imagined; and others said, such a profession of faith by such princes was a more effectual preaching than that which had been stopped. “Christ,” exclaimed Jonas (Melancthon's companion), “is in the diet, and he does not keep silence: the Word of God is indeed not to be bound.” And forth these words have gone through a world wider than that to which the apostles preached. After a pause, the second part, the articles about the abuses of the church of Rome, was read and heard with profound silence by the mitred prelates of that church who were there assembled. As to the emperor, he slept during the whole of the reading, or seemed to sleep, like a tiger ready to espy the most convenient moment for leaping upon his prey. In the mean-

time, he calculated, undoubtedly, what political capital he could make of the Protestants against the pope. Luther.

Luther addressed a letter to the cardinal elector of Mainz, demanding nothing but one article, but insisting upon that unconditionally—the liberty of preaching the gospel. “Neither emperor,” he says, “nor pope has the right of forcing any one to believe.” With Melancthon and the other friends he insisted upon their leaving Augsburg immediately. “Home—home—home!” he exclaimed. “Might it please God that I should be immolated at this council, as John Huss was at Constance!” All the sayings of Luther during this crisis are sublime and of a truly prophetic character. He foresaw that now every effort would be made at Augsburg to destroy the principles of the Reformation by a treacherous compromise and a false peace. “The diet,” he said, “is a regular dramatic piece: first, there is the prologue, then the exposition, then the action,—now comes the catastrophe; but I think it will not be a tragic, but a comic end.” And, indeed, so it turned out to be, tragical as it was. The first triumphant effect of the confession soon passed away; the new converts, particularly among the prelates, withdrew; the fanatical party doubled its efforts, and Charles gave way to it, and aided its ends by all diplomatic artifices. Melancthon was caught. He entered into conferences in the vain hope they would lead to concord; he declared himself ready to maintain and obey the supreme authority of the pope, if he would, by an act of clemency, connive at, if not approve, some points which they could not change. During the treacherous conferences which now began, the emperor tried to intimidate the elector by threatening not to grant him the investiture, which the elector claimed, however, as his hereditary right as brother of his predecessor; and to frighten all the Protestant princes and the Protestant imperial city of Augsburg with measures of violence, by calling in the imperial troops, and keeping the gates closed. The landgrave escaped. This act caused dismay among the ranks of the Catholics, for a war could not be risked at this moment. The Romanists changed their tactics; they conceded, or rather feigned to concede; for, meanwhile, the pope had declared solemnly that he would not give up those very points. The Protestants acknowledged the jurisdiction of the bishops and the supremacy of the pope. A cry of indignation rose among the princes, and, above all, among the brave citizens of Augsburg. “Rather die with Jesus Christ,” they declared, “than conquer without Him the favour of the whole world.”

At this critical moment Luther's indignation rose to a holy wrath, like that of the prophets of old. “I understand,” said he to Melancthon, “that you have begun a marvellous work, namely, to make Luther and the pope agree together; but the pope will say that he will not, and Luther begs to be excused. Should you, however, after all, succeed in your affair, I will follow your example, and make an agreement between Christ and Belial. Take care that you give not up the justification by faith; that is the heel of the seed of the woman to crush the serpent's head. Take care not to acknowledge the jurisdiction of the bishops; they will soon take all. In short, all your negotiations have no chance of success unless the pope will renounce papacy. Now, mind, if you mean to shut up that glorious eagle, the gospel, in a sack, as sure as Christ lives, Luther will come to deliver that eagle with might.”

But Melancthon was changed: Luther's voice had lost its power over him. The extreme Protestant views maintained in a declaration which Zwingli had delivered to the emperor, disposed him to cling still more to Rome. All seemed for the moment lost; but Luther's faith had discerned the way in which God meant to save the Protestant cause, and had said,—“Christ lives; he who has vanquished the violence of our enemies, can also give us the power of

Luther. breaking through their artifices." The Romanists fortunately insisted upon four points,—celibacy, confession, the denial of the cup to the laity, and the retaining of private masses. This was too much: the conference separated. The Romanists now conceded the cup and the marriage of the priests; but they would not give up the private masses, nor the obligation of confession and penance for the remission of sin, and required an acknowledgment of the meritorious character of good works. Melancthon stood firm, on which the emperor and Clement played out their last card: an accumenical council should be convened; but, in the meantime, the Protestants should conform to the doctrine and rites of the Catholic church. Charles accompanied this communication with the most insulting threats against the Protestant princes, who declined to negotiate, and declared their resolution to abide by the *status quo* of Worms until the council should assemble. The emperor indeed went so far as to forbid the princes to quit Augsburg, but the elector was firm as a rock: his son left the town on the 12th of September. Melancthon had regained his courage and sagacity. When Luther heard what was taking place, he raised his voice from Coburg—"Depart, depart! even if it must be, with the curse of pope and emperor upon you. You have confessed Jesus Christ, you have offered peace, you have obeyed the emperor, you have supported insults of every kind, you have withstood blasphemies: now I will encourage you,—as one of the faithful members of Jesus Christ. He is making ready our enemies as victims for the sacrifice; he will presently consume their pride and deliver his people. Yes, he will bring us safely out of Babylon and her burning walls." When the emperor saw that the elector was resolved on departing, he communicated to the five princes and the six towns (four more having joined since Nuremberg and Reutlingen), a proposal for a recess, or definitive decree of the diet,—that six months' should elapse to give time for an arrangement; and meantime, Protestants and Catholics should unite in a common attack upon the Anabaptists and those who denied the holy sacrament, the Zwinglians; but the Protestants alike withstood threats and flatteries; and the elector took his leave, as he had announced, on the 23d of September.

9. Last 15 years of Luther's life, and his death—1530-1546.

The author of this article cannot agree with the saying of the eloquent historian of the Reformation, that if the glorification of man was the purpose and end of God's ways, and not God's glory alone, one must wish Luther had died at the Wartburg. We have seen that it was he who, in 1524, pacified Wittenberg and Saxony by his reappearance, and achieved wonders as a practical reformer; and, in 1525, attempted, as pacificator of Germany, what nobody but himself could and would have done. But whose was the never-shaken mind? Who among the German theologians and Reformers was the organ of God and of the German nation during the greater part of the momentous diet of Augsburg? Who else but the man in the solitary tower at Coburg! From this time forth, however, he had nothing left to do but to look the tragedy in the face, as a believer in God and His kingdom on earth, praying and preaching, and finally to die the death of a faithful and hopeful Christian saint. All the rest is patient, suffering, martyrdom.

Some of the most powerful Romanist princes, the archbishop of Mayence at their head, assured the elector, on his departure, that they would never join the emperor in adopting any violent measures against him, although the brother of the archbishop Joachim, elector of Brandenburg, had presumed to promise in their name that they would. Even Ferdinand said some civil words. But why? Simply because (as Charles could not refrain from saying in his wrath) the emperor was more than ever resolved to resort to arms. "Nothing but armaments will have any effect," he said. Indeed, he announced this as his resolution im-

mediately to the pope, and requested him to summon all Christian princes to assist him. The Catholic league was signed on the 13th of October. The anti-reformatory movement was begun in the town of Augsburg itself. The answer to this was the declaration of sixteen imperial towns, instead of six, that they would not grant any subsidies against the Turks so long as the affairs of Germany remained unsettled. The Zwinglian and Lutheran towns shook hands; and this was the expression of the real feeling of the whole German nation, only priests, pastors, and theologians excepted. The Protestant dignitaries declared that they rejected the imperial closing declaration, as the emperor had no right to command in matters of faith. Luther was the organ of the universal feeling of the German people, when he exclaimed, "Our enemies do not fill me with fear. I, on the contrary, shall put them down in the strength of the Lord. My life shall be their executioner; my death their hell." Indeed, his work was accomplished—for all countries and for all ages. The rest of his life was one long pang, although he did not live to see the most dreadful calamity,—the breaking out of the civil war of religion which began immediately after his death. He wrote an address to the German nation, warning them not to yield to Rome and not to trust any negotiations; "for," said he, "they know no argument but force. Be not deceived by their words about obedience to the church. The church is a poor erring sinner without Christ; not the church, but Christ is the faith." The cause of the Reformation made progress; the Protestant alliance, begun by the convention of Schmalkalden, gained new members; Denmark acceded, and Joachim II. became as staunch a defender of the faith of his mother as Joachim I. had been its violent enemy. As Luther had prophesied, the negotiations with the popish party in 1541, renewed at Ratisbon, led to no result. The emperor, at the diet of Spire in 1544, dared no longer refuse to the Protestants the equal right which they claimed. The Romish council opened at Trent in 1544, and its first proceeding was to read the pope's anathema against the Protestants.

It is in this latter period (from 1539 to 1543) that a secret letter of advice, drawn up by Melancthon, was given by Luther and his friends to the landgrave Philip in answer to his pressing request (sanctioned by the landgravine, who suffered from an incurable inward disorder) to deliver him from the sin of fornication, by allowing him to marry a lady of the landgravine's court. After the masterly discussion of this subject by Archdeacon Hare in his *Vindication of Luther*, republished (1555) from the notes to his *Mission of the Comforter*, it is not necessary, least of all to English readers, to enter into details in order to prove the report of Bossuet to be a tissue of falsehoods and malignity. We limit, therefore, ourselves to stating the decisive facts. *First*, The error committed in this secret advice by the Reformers was a perfectly sincere one; it arose from an indistinct view of the applicability of the patriarchal ordinances and of the Mosaic law, which admits a second wife legally, as indeed Moses himself seems to have had two wives at the same time. Now, as the Reformers could not show an express abrogation of those ordinances and of this law, they were led into this sad mistake. *Secondly*, There was in their advice no worldly regard whatever, as to any benefits and advantages, which might accrue to themselves, or to the cause of the Reformation. They knew that the landgrave had his whole heart in the cause of the Reformation, and had often risked his life and states for it. *Thirdly*, When in 1540, Philip divulged the secret, contrary to his promise, they spoke out and confessed their mistake, and Melancthon was brought by his grief to the verge of the grave. *Fourthly*, When, in the course of the controversy, Bucer published, in 1541, his pamphlet in defence of polygamy (under the name of Huldéric Neobulus), Luther pro-

Luther.

Luther.
||
Lutherans.

nounced his judgment upon the book and on the subject in the following solemn words:—"He who desires my judgment upon this book, let him hear. Thus says Dr Martin Luther on the book of Neobulus: He who follows this rogue and book, and thereupon takes more than one wife, and means that this should be a matter of right, may the devil bless his bath in the bottom of hell. This, God be praised, I well know how to maintain. . . Much less shall they establish the law, that a man may separate himself from his wife rightfully, when she has not already separated herself by open adultery, which this rogue would also like to teach." We possess also the sketch of his intended full reply to Bucer's book; and there we find the following sentence:—"We have already shown in a number of books, that the law of Moses does not concern us, and that we are not to look to the examples in the history of the saints, much less of the kings, to their faith, and to God's commandments."

The dark side of this latter portion of Luther's life is his controversy with the Reformed. He seemed now and then inclined to yield to their entreaties for a union, as is shown by his letter of 1531 to Bucer of Strasburg; and he declared his sincere wish for a union to the landgrave in 1534. He does not think the work ought to be precipitated, but he prays to live to see it take place. The concord of Wittenberg, begun by Bucer in 1536, which left it just possible to the Reformed not to see their view of the sacrament excluded, has his cordial sympathy. Finally, on the 17th February 1537, he writes to the burgomaster of Basel, James Meyer, in terms which excited among the Swiss the hope he would give up his exclusive views. But when Ecolampadius published the writings of Zwingle, after this great and holy man had died a patriot's death in the battle of Cappel, Luther became so incensed, that he wrote, in

1544, two years before his death, the most violent of all his sacramentary treatises,—*A Short Confession respecting the Lord's Supper*.

Luther.
||
Lutherans.

However, his last word, on his deathbed, was one of peace. He is credibly reported to have said to Melancthon in the course of a dying conversation,—“Dear Philip, I confess to have gone too far in the affair of the sacrament.”

The year 1546 began with unmistakeable indications that Charles was now ready to strike a decisive blow.

Luther had been suffering much during the last few years, and he felt his end to be near at hand. In the month of January 1546, he undertook a journey to Eisleben in very inclement weather, in order to restore peace in the family of the counts of Mansfeld; he caught a violent cold; preached four times; and took all the time an active part in the work of conciliation. On the 17th of February he felt that his release was at hand; and at Eisleben, where he was born, he died, in faith and prayer, on the following day. Nothing can be more edifying than the scene presented by the last days of Luther, of which we have the most authentic and detailed accounts. When dying, he collected his last strength and offered up the following prayer:—"Heavenly Father, eternal, merciful God, thou hast revealed to me thy dear Son, our Lord Jesus Christ: Him I have taught—Him I have confessed—Him I love as my Saviour and Redeemer, whom the wicked persecute, dishonour, and reprove. Take my poor soul up to thee!" Then two of his friends put to him the solemn question,—“Reverend Father, do you die in Christ and in the doctrine you have constantly preached?” He answered by an audible and joyful “Yes;” and repeating the verse, “Father, into thy hands I commend my spirit,” he expired peaceably, without a struggle, on the 18th of February 1546, at four o'clock in the afternoon. (C. C. J. B.)

LUTHERANS, that body of Christians whose system of religious doctrine originated with Luther. They are more nearly allied to the Romanists in point of doctrine than are any of the churches of the Reformation. Luther maintained the doctrine of consubstantiation, or the real simultaneous coexistence of the body and blood with the bread and wine in the Lord's Supper. As to the use of ceremonies and forms, there is considerable license permitted among the Lutherans. They accordingly, differ much in the number and nature of their public rites. The general form of government in the Lutheran church is intermediate between the Episcopal and Presbyterian systems. From a misapplication of the doctrine that Christians are accountable to God alone for their religious sentiments, there is a considerable degree of liberty given to their teachers in relation to the symbolical books. These are the three ancient Creeds, the Augsburg Confession, the Articles of Smalcald, the larger and smaller Catechisms of Luther, and the Form of Concord. The fullest edition is that of Hase, by Francke, entitled *Libri Symbolici Ecc. Luther., cum Appendice Quinquepartita*, Leipsic, 1847. The Lutheran church prevails in Germany, Denmark, Norway, and Sweden. Their existence as a distinct body among the adherents of the Reformed cause dates strictly from the publication of the *Formula Concordiæ* in 1580. This act divided the church of Germany into Lutherans and Calvinists, and each of the two branches began from that time forward to have a separate history. Various efforts were made to heal this division, but in vain, until in 1817, when a somewhat mechanical union was effected on the basis of a declaration promulgated by a synod convened by royal authority at Berlin. Since that time the two confessions have been held within the pale of the same church, and not unfrequently been preached by collegiate ministers within the same walls; and in the perplexity of such virtual

disunion, many of the most gifted minds in Germany have addressed themselves to the task of finding some higher exposition of truth which shall include and combine the two phases of Reformed doctrine. This has led to a keen discussion in regard to the nature of the differentiating element in the two systems; and the simple enumeration of the formulas which Lutherans themselves have given, will tend to show the disturbing force which one anomalous doctrine has exercised in breaking up the common faith of the two great Reformers.

One scheme of difference points to the original dispute. As the first quarrel arose in regard to a passage of Scripture (and Lutheranism has developed itself in a long series of diverging exegetical systems), the disturbing force is traced to a fundamental difference in regard to the relation of reason to Scripture. The Reformed church is charged with exalting reason above the mysteries of revelation, which the Lutheran church receives in their simple and naked antagonism to the apprehensive powers of the human intellect. In this view the controversy between the Lutheran and Reformed systems is the same in kind, although not in intensity, as that which is waged between the Reformed party and the Church of Rome.

A second scheme points to a difference in original purpose. The Lutheran Reformation aimed at counteracting a Jewish element in Catholicism, and in this one-sided purpose unconsciously received a Gnosticizing tone; while the Calvinistic scheme, in combating a purely heathen element in the papacy, unconsciously fell, at least in its ethical creed, into a Judaizing cast of thought. Another formula defines the Lutheran church as the church of theologians, giving prominence to an objective theology, and the Calvinists as the church of collective believers, giving undue prominence to a subjective anthropology. In antagonism to this is another scheme, which defines Lutheranism as an anthro-

Luton
||
Luxem-
burg.

pology with only a dwarfed theology, and Calvinism as a theology with a very defective doctrine of man. Calvinism severs God from the fallen creature; Lutheranism regards the creature as existing in God. Calvinism views salvation as a work of God, planned and executed utterly apart from man; Lutheranism, in asserting the resistibility of grace, recognises an element of human will in the redemption of each individual. Calvinism sees in the means of grace an efficacy imposed by God, and powerful only through faith; Lutheranism accords to them an innate power appreciable universally to man.

A brisker formula than any of the preceding defines Lutheranism as rooted in the absolute blessedness of intelligence to be developed, and Calvinism as founded on the absolute meritoriousness of fact to be appreciated. Another theory detects a fundamental difference in the doctrine of man's relation to God. The Lutheran sees the Creator immanent in the creature; the Calvinist recognises merely a relation of dependence. This leads to a different estimate of the world's history: Lutheran theology mingles in its doctrine of sin the conception of eternal love; the Reformed theology excludes everything but righteous law: Lutheran divines dwell on the traces of God's love in man's history; the Reformed systems dwell peculiarly on the unfolding of God's attributes.

It seems easier to apprehend that the difference lay in the relation of the two parties to tradition: Calvinism was systematized from Scripture alone; Lutheran theology accorded to tradition a regulative power. Calvinism was a return to the primitive sources of revelation; the Lutheran church was only a new phase of Latin Christianity. (Consult Göpel's *Eigenthümlichkeit der Luth. u. Reform. Kirche*, 1837; Ullmann's *Zur Charak. der Ref. Kirche in the Stud. und Krit.* for 1843; and Schneckenburger, *Vergleichende Darstellung des Luth. und Ref. Lehrbegriffs*, 1855.)

LUTON, a market-town of England, Bedfordshire, on the right bank of the Lea, 31 miles N.N.W. of London. It consists of three long irregular streets diverging from the market-place. The chief public edifice is the church, a fine old building of the Gothic and later English styles, containing a hexagonal font, and a number of interesting monuments. There are also a town-hall, a market-house, a literary and mechanics' institute, besides several chapels and schools. The inhabitants are principally employed in straw-hat making, brewing, and trading in agricultural produce. Market-day, Monday. Pop. (1851) 10,648.

LUTTERWORTH, a market-town of England, Leicestershire, on the Swift, an affluent of the Avon, 13 miles S. of Leicester. In the parish church, said to be erected about the beginning of the twelfth century, Wickliffe delivered his celebrated discourses. Market-day, Thursday. Pop. (1851) 2446.

LÜTZEN, a small town of Prussian Saxony, between Leipsic and Weissenfels, 11 miles W.S.W. of the former. It is celebrated as the scene of two important battles—one on the 6th November, 1632, between the Swedes under Gustavus Adolphus, and the Austrians under Wallenstein, when the former, though victorious, lost their gallant general; the other on the 2d May 1813, when the Prussian and Russian allied army was defeated by the French under Bonaparte. Pop. 1961.

LUXEMBURG, or LUXEMBOURG, a province of Belgium, in the basins of the Meuse and Moselle, formerly part of the grand duchy of Luxembourg, bounded on the N. by Liège, S. by France, E. by the duchy of Luxembourg, and W. by Namur. Its length from N. to S. is about 67 miles, and its breadth E. to W. 37 miles; area, 1705 square miles. It is traversed from S.W. to N.E. by a branch of the Ardennes, whose highest summits do not exceed 2000 feet. Its surface is extremely rugged, covered with wood and extensive morasses. The soil is nowhere

Luxem-
burg.

very fertile, being thin and gravelly. About one-third of the unwooded surface is devoted to pasture—sheep, horned cattle, pigs, and horses being reared for export in great numbers. The latter especially are of a hardy and spirited race, and are bought for the light cavalry in France. There are considerable mines of iron, and lead and copper are also found; with marble, slate, freestone, marl, and gypsum. Besides iron, there are manufactures of cloth, tulle, earthenware, leather, nails, and potash. Of the soil, the principal productions are,—wheat, potatoes, tobacco, wine, and fruit. The most important article of commerce is the bark of the oak, which is employed in the great tanneries of Stavelot and Malmedy, and in England; and the oakwood itself, which is exported to Liège and the Netherlands by way of the Meuse. The province is divided, for administrative purposes, into five arrondissements—Arlon, Bastogne, La Marche, Neufchâteau, and Virton. Arlon, the capital, is a place of some size and importance; but on the whole, the province is thinly populated. In 1855 it amounted to 196,074. It sends two senators and five representatives to the Belgian legislature.

LUXEMBURG, *Grand Duchy of*, one of the states of the German Confederation, and part of the kingdom of the Netherlands, is bounded N. and E. by Rhenish Prussia, S. by France, and W. by Belgium. Its length from N. to S. is about 48 miles, and its breadth from E. to W. 34; area, 986 square miles. Its surface is elevated, being part of the plateau of the Ardennes, and largely covered with wood and heath. The River Moselle, which bounds it on the S.E., drains the greater part of it; and the Sure and its tributaries Our and Alzette, and the Meuse and its affluents Ourthe and Lesse, the remainder—the Sure itself falling into the Moselle. It is divided into three districts—that of Luxembourg, Grevenmacher, and Diekirch, containing eleven cantons; and, in 1855, a population of 189,480. The bulk of the population is employed in agriculture, which is rather in a backward state, the nature of the soil being adverse; and there is a considerable amount of pastoral country. Wine is grown to some extent, but it is of inferior quality. The chief agricultural products are corn, vegetables, hemp, flax, and hops. Iron is found in the eastern districts, and about 9000 tons are annually manufactured, wood being employed as fuel. The quarries of lime and slate are pretty extensive. Lead was also worked at one time, but is now exhausted or abandoned. The population of the whole of Luxembourg, including the Belgian province, with few exceptions, speak German, though French is understood. In religion they are, almost without exception, Roman Catholics. There was till lately a great want of schools and colleges, but a movement has taken place in this respect.

Luxembourg was originally governed by counts, who were at the same time sovereigns of Brandenburg. In 1354 it was erected into a duchy by Charles IV.; and in 1443 fell to Philip of Burgundy by marriage, and through Philip to the House of Spain, with whom it continued entire till, at the peace of the Pyrenees in 1659, part of it was ceded to France, and took the name of French Luxembourg. This latter portion is now comprised in the department of the Moselle. In the first revolution France again appropriated the whole; but in 1814 it was given to Holland in compensation for the German principalities of Nassau, Dillenburg, Siegen, Hadamar, and Dietz; and was organized by the King of the Netherlands as a foreign province, with a constitution and administration of its own. It was again dismembered in 1831, in consequence of disputes following on the Belgian revolution of 1830; and the portion W. of a line drawn from the French to the Prussian territory, a little to the E. of Arlon and Bastogne, given to Belgium.

LUXEMBURG (German, *Lützelburg*), capital of the old grand duchy, and now of the Dutch province, is situate

Luxem-
burg
||
Luzon.

in N. Lat. 49. 37., and E. Long. 6. 9.; 100 miles S.E. of Brussels, 66 S.S.E. of Liège, and 115 W.S.W. of Frankfurt-on-the-Main. As a fortress it belongs, by the treaty of Vienna, to the German Confederation, and is garrisoned with 6000 Prussian troops. Naturally strong, and carefully strengthened by its successive possessors, it is now, according to Carnot, the strongest place in Europe except Gibraltar, and the only *point d'appui* from which France can be attacked from the side of the Moselle. It consists of an upper and a lower town; the former being the citadel, and standing 200 feet higher than the latter, with which it communicates by flights of steps and zig-zag streets cut in the solid rock. The lower town occupies a deep valley, watered by the Peterburn and Alzette, crossed with fortifications, and divided into two quarters, viz., Grindel and Pfaffenthal, by the projecting rock called Le Bouc. This is the most remarkable part of the works; it is hollowed from top to bottom, commands the whole valley up and down, and its casemates, cut in the solid rock, are capable of holding 4000 men. The walls have been greatly strengthened under the direction of the German diet, and a new fort built outside the gate to Treves. The most remarkable buildings are the ancient cathedral, partly used as a barrack, and the governor's house. The town possesses also four churches, three chapels, an atheneum, seminary for priests, a normal and several elementary schools, and a recently erected market-place. There are two convents, the Dominican and Franciscan, in a very ruinous condition. The chief manufactures are of wax and leather (common and chamois); there are also breweries and distilleries. The commerce consists of gold and silver goods, paper, iron, wine, porcelain, and some other articles. Luxemburg is an episcopal see. Pop. about 12,000.

LUXEMBURG, FRANÇOIS HENRI DE MONTMORENCY, *Duke of*, and marshal of France, a renowned general in the service of Louis XIV., was born in 1628. He was with the Prince of Condé at the battle of Rocroi in 1643; and in 1688 he distinguished himself at the conquest of Franche Comté. In 1672 he commanded in chief the French army in Holland, when he defeated the enemy near Woerden and Bodegrave; and the retreat which he effected in 1673 was universally admired. He became marshal of France in 1675, gained the battle of Fleurs in 1690, that of Steenkirk in 1692, and that of Nerwinde in 1693. He died at Versailles in 1695.

LUXEUIL, a town and watering-place of France, department Haute-Saône, near the rivers Lanterne and Breuchin, 16 miles N.E. of Vesoul. It is situate at the extremity of a fertile plain, and is well laid out in substantially built streets, many of which are ornamented with fountains. The edifices of chief interest are,—the ecclesiastical college, formerly a Benedictine abbey, founded in the fourteenth century; the old town-hall, erected about the same time; and a mansion, once occupied by Cardinal Jouffroy. Besides these there is a large bath-house in the centre of a beautiful park, plentifully supplied with thermal spring water. The town has manufactures of ironmongery, straw hats, and brandy; and carries on a brisk trade in agricultural produce. It was celebrated for the efficacy of its waters in the time of the Romans, who erected baths here, of which the remains are still extant. In the sixth century an abbey was founded by St Colomban, which afterwards became one of the most famous in France. Pop. 4100.

LUXOR, or EL UKSUR, near Thebes. (See EGYPT.)

LUZON, or LUÇON, the largest of the Philippine Islands, in the Eastern Archipelago, lies between N. Lat. 12. 10. and 18. 43., E. Long. 119. 45. and 124. 10. In form it is very irregular, resembling in some measure a bent arm, and the coast is deeply indented with gulfs and bays. It consists of two peninsulas,—the northern called Luzonia, embracing four-fifths of the whole; and the southern, or Ca-

marines, running nearly at right angles with the other. These peninsulas are joined by the Isthmus of Tayabas, about 50 miles long, and varying in breadth from 10 to 20 miles. The length of the entire island is about 550 miles, and its breadth varies from 30 to 135 miles, excluding the isthmus; its area has been estimated at 52,328 square miles. The most remarkable bays on the western coast are those of Lingayen, Manilla, Balayen, and Batangas; on the eastern, those of Difun, Lamon, St Miguel, Lagonoy, and Albay. Like the other islands of the same group, it is of igneous formation, its basis chiefly granite; and like them it is traversed in its whole length from N. to S. by a range of mountains, the Caraballos, inclining chiefly to the eastern coast, to which they impart a bold and precipitous character; and branching in the northern peninsula towards the eastern and western extremities, Engaño and Bojeador. The branch which terminates in the promontory of Engaño is the highest in the island, and is called the Gran Cordillera, or Sierra Madré. The loftiest summit, however, in this range, called Banajao or Mujayjay, N. Lat. 14. 2., E. Long. 121. 14., is only 6214 feet above the sea, not more than half the height of the mountains of Sumatra and Java. These mountains are all of volcanic formation; and in the peninsula of Camarines some are still active volcanoes. From that of Mayon, in the province of Albay, N. Lat. 13. 14., E. Long. 123. 34., eruptions took place in 1766 and 1814,—the town of Albay being entirely destroyed by the latter; and from the volcano in Lake Taal, about 1667 feet high, an eruption took place in 1754, which destroyed the town of Taal. These eruptions were accompanied by extensive earthquakes. The volcano of Balusan, in the S., serves as a kind of beacon, and is on that account well known to mariners. Lofty and extensive plains and valleys are inclosed by these ranges, the largest being those of Cagayan, Abra, and Agno in Luzonia. The island has numerous rivers and streams, the largest of which is the Cagayan, passing through the plain of that name, and known also as the Tajo (*Tagus*) and the Apari, navigable to a considerable distance for small vessels, and falling into the sea, after a course of about 200 miles, in the northern region at the town of Apari. Passing through the same plain, and falling into the sea farther W., is the Abulug. Into the Bay of Manilla fall the united waters of the Chico and the Grande, the former issuing from the Lake of Camaren. The united stream passes through the fertile province of Pampanga, and has a course of about 23 leagues. Two considerable rivers derive their names from the plains of Agno and Abra; the former rises in the Central Caraballos and falls into the Gulf of Lingayen; the latter rises in the Western Caraballos, Lat. 16. 47., and falls into the sea by three branches near the headland of Namagpacan. It is navigable for small vessels.

The most extensive lake in the Philippines is the Laguna de Bay, so called from the town of Bay at its S. extremity. It has an area of about 350 square miles, and an average depth of about 15 fathoms. Into this lake flow fifteen different rivers, and its surplus waters are carried off by the River Pasig, which falls into the Bay of Manilla near the city of that name, after a course of about 21 miles. This lake contains several islands, the largest of them, Talim, being 3 leagues in length by 1 in breadth. Its waters are everywhere potable, and it has valuable fisheries. The Pasig is navigable for vessels of 500 tons, and though not one of the largest, is the most important river of Luzon. After the Lago de Bay is the deep Lake Taal already mentioned, between Lat. 13. 52. and 14. 6., and which has a circumference of 15 leagues; then Lake Cagayan in the province of Cagayan, about 12 leagues in circumference; lastly, Lake Camaren, Lat. 15. 40., about 6 miles long and 5 broad in the dry season. There are also temporary lakes, called by the natives *Pinug*, caused by the rains, and which either entirely disappear or

Luzon.

Luzon. are much reduced in the dry season. The Pinag of Candava, in the province of Bulacan, 8 leagues broad sometimes during the rains, affords in the dry season rich and extensive pastures.

On the western side of the island the fall of rain is very great, the rainy season lasting from the middle of June to the middle of September; on the eastern, the rainy season sets in with the N.E. monsoon, which prevails from November to March; this difference is owing to the chain of the Caraballos. The N.W. monsoon prevails from April to October, the summer or dry season. The annual fall of rain at Manila ranges between 84 and 114 inches. It sometimes rains without intermission for a fortnight. During this season the rivers overflow their banks; lakes are formed; and, owing to the paucity of stone bridges and the frequent loss of the wooden ones, whose places are supplied with cane-rafts, inland communication is rendered extremely difficult. The heat at Manila at no time exceeds that of a Madrid summer, as those allege who have experienced both. The range of temperature in the former city is from 19° to 29° Reaumur.

The forests, with which the island is extensively covered, afford excellent timber for house and ship building; the dongon and molavé are considered by the Spaniards superior to the teak. The rice crops afford not only the principal food of the population, but a surplus for the Chinese market; maize and wheat have been introduced by the Spaniards. The yam (*ubi*) and the batata are the farinaceous roots cultivated. The banana, mango, pine-apple, orange, and musk melon, are abundant; the mango is said to be of peculiar excellence. The sugar-cane is grown; oil is procured from the sesame and cocoa-nut; and spigits from the buri and the nipa palm. Indigo, coffee, and cocoa are of comparatively recent introduction. Cotton and the piña, and abaca banana, afford materials for textile fabrics; the fibres of the latter, mixed with Chinese silk, form the cloth for which the island is famous. Tobacco is grown to some extent. The husbandry of Luzon, and the system of irrigation, notwithstanding the abundance of water, is by no means so perfect as in Java and some other islands of the Archipelago; but such is the productiveness of the soil that it ranks next to Java in point of fertility and population. Land is very valuable in Luzon, ranging from L.22 to L.125 per English acre—about ten times the usual value of land in tropical Asia; irrigated land being highest in price. The greatest portion of the cultivated land is divided among small proprietors; the larger holdings are farmed on the métairie system, half the produce being paid to the proprietor. The crown holds the uncultivated lands, and receives from pious foundations and the European settlers a nominal tithe, or quit-rent. Besides the lands under wood and cultivation, there are extensive plains, furnishing pasture for herds of horses, oxen, and buffaloes, none of which are indigenous, but nevertheless exist wild to an extent unknown in the rest of the Archipelago. Of the other wild animals the most remarkable are the mountain cat (*Gato de Montes*), the only animal of the feline tribe; the hog, the only pachyderm in the island; and the civet cat. The adjutant crane, the swallow which furnishes the edible nest, great numbers of the pigeon and parrot kind, and the common fowl in a wild state, are found. Serpents, alligators, and tortoises abound. The rivers, lakes, and surrounding ocean swarm with excellent fish, furnishing employment to a great part, and, with rice, the chief food of the whole of the population. Of fresh-water fish, the sabalo, taken in Lake Taal, whither it ascends from the sea for the purpose of spawning, and the dalag, are most esteemed. The tripang, a sea fish taken in the shallow bays, is cured, and forms an important item of export to China. The usual tropical insects infest the island; mosquitoes and ants are the special plagues; but the hurricanes to which it is exposed are an excellent protection against the locust.

Besides the civilized and savage Malayan races (the former inhabiting and cultivating the valleys, the latter subsisting by the chase among the mountains), the island contains tribes of Aetas, a race better known by the Spanish name Negritos, applied to them from their resemblance to the negro, without being so tall or so black. The Aetas, who are found only in the five larger Philippines, exist in the rudest possible manner, and are in a state of incessant hostility with the other islanders. The number of those in Luzon at all under control amounts to about 8300. The population of Luzon, which is very unequally distributed, was in 1850 computed at 2,534,613, having nearly tripled itself in the course of half a century.

The most considerable branch of industry is the weaving of cotton and the other fabrics already mentioned, for home use and exportation. This manufacture is most largely carried on in the provinces of Ilocas, Camarines, and Tondo. Some of the piña cloth made is extremely delicate and beautiful; and it is rendered more valuable by the exquisite embroidery of the native women. Their matting from the buri palm, and cordage from the coarser abaca, are much esteemed. The art of dyeing cloth is extremely imperfect; that of printing it quite unknown. The women are remarkably skilful in gold filagree work. Salt is made from sea water by boiling and by exposure to the sun, and from some plants by burning them. This manufacture is carried on in the province of Pangasinan, which also provides the neighbouring provinces with oil and sugar.

The coasting and inland trade of Luzon are attended with difficulties,—the former from the equinoctial hurricanes, and the monsoons themselves rendering only one voyage practicable to the native traders in six months; the latter from the rains and the condition in which they leave the roads. Manila is the central point; but there is a good deal of trade between the various provinces,—in rice from the more productive, in cotton from Ilocas, indigo from Bulacan and Laguna, piña and abaca fabrics from Camarines. Timber and canes are floated down the rivers in rafts. The foreign trade of the Philippines is confined by law to Manila,—the staple exports being rice, sugar, tobacco, coffee, indigo, hides, ebony, tortoise-shell, tripang, abaca hemp and cloth, hats, and gold dust. Wine is imported from Spain; cotton and woollen fabrics, iron and copper, from Great Britain; and silk from China. (See MANILLA.) For the China trade Luzon has peculiar facilities, the number of voyages not being restricted by the monsoons.

The name of the island is probably derived from that of the western promontory of the Bay of Manila, and that from its supposed resemblance to the mortar (*lozong*) used by the natives in husking rice. The Philippines were discovered by Magellan in 1521; but it was not till fifty years after that Legaspi landed in Manila Bay, where he found a thriving Mohammedan town. He found no great difficulty in subjugating the island. The people were little advanced in civilization, the use of fire-arms being almost unknown; and they were divided among themselves. Except some piratical expeditions from China and Japan, and some abortive attempts on the part of the Portuguese and Dutch, the Spaniards were left in undisputed possession of the island till the invasion by British troops from Madras in 1762. The armament consisted of thirteen men of war and a force of 2300 men. Manila was stormed and sacked, but restored by the treaty of Paris after ten months' occupation. (See PHILIPPINES.)

LYBIA, or LIBYA, a name anciently given to all that part of Africa lying between the borders of Egypt and the River Triton, and comprehending Cyrenaica, Marmarica, and the Regio Syrtica. (See AFRICA.)

LYCÆUM. (See ATHENS.)

LYCAON, a king of Arcadia, son of Pelasgus V. and Melibæa, or Cyllene. Some make him son of Hermes (Sch.

Lycia.

ad Theocr. i. 124). It has been supposed by some that there are two distinct kings of the same name, but there seems no sufficient reason for such a supposition. He was the father of many sons; some say fifty, and others only twenty-two. According to the traditions of the Arcadians, he was the first who instituted the worship of Zeus as the Supreme Being, founding Lycosura upon the top of Mount Lycæus (Paus. viii. 2, § 1). He is said to have offered human victims on the altar of Zeus; and from this the poets embellished the story in the manner that Ovid tells it (Ovid, *Met.*, i. 198). Rumours of the impiety of Lycaon and his sons reached Jupiter, and he came down to examine their truth. They placed before him part of the body of a child dressed for dinner, when Lycaon and all his sons, with the exception of Nyctimus, were killed by Zeus with a flash of lightning, or, as others say, were changed into wolves (Tzet. *ad Lycoph.* 481; Eratosth., *Catast.* 8). Some say that the flood of Deucalion was the immediate consequence of the crimes of the sons of Lycaon (Apollodor. iii. 8, § 1).

LYCAONIA, a district of Asia Minor, was differently bounded at different times. Xenophon mentions it as extending westward from Cappadocia to the city of Iconium, which was afterwards situated near its centre. Under the sway of the Romans it suffered frequent dismemberments, and often changed its limits. According to Strabo, however, it was skirted on the N. by Galatia, on the E. by Cappadocia, on the S. by Mount Taurus, and on the W. by Pisidia and Phrygia. From the same author we learn that Lycaonia abounded in sheep and wild asses, and produced large quantities of salt. The chief towns were Iconium, Lystra, Derbe, Laodicea, Combusta, and Laranda. Daring and lawless, the Lycaonians were much addicted to war and rapine, and are first mentioned in history as resisting Cyrus the younger when passing through their country on his famous expedition. They set at defiance the power of the Persians; and though subdued successively by Alexander the Great, the Seleucidæ, Antiochus, Eumenes of Pergamus, and the Romans, they still preserved their nationality. In the Acts of the Apostles they are represented as having a language of their own.

LYCIA, a country of Asia Minor, was bounded on the W. by Caria, on the N. by Phrygia and Pisidia, and on the E. and S. by the Mediterranean Sea. From the account given by Herodotus, we may infer that the country was originally called Milyas, and was inhabited by two tribes, the Solymi and Tremilæ; or Termilæ, that a band of adventurers under Lycus, son of Pandion, drove the former tribe back to the northern mountains, and subdued the latter; and that, while the northern parts of the country still retained the ancient name of Milyas, the remaining parts were called Lycia, after the name of their conqueror. The northern part of Lycia is rendered rugged by offsets from Mount Taurus. The two principal rivers, the Limyrus in the E., and the Xanthus in the W., both flow southward into the Mediterranean. Pliny represents the country as fruitful, and noted for its firs, cedars, and plane trees. It appears to have been governed in the time of Homer by kings, but afterwards by a congress of deputies from the different free cities. By this congress, the chief magistrate, called Lyciarch, the judges, and other officials, were chosen, and the general affairs of the country administered. In the time of Strabo the free cities amounted to twenty-three. Of these, the principal were Xanthus, Patara, Olympus, Myra, Pinara, and Tlos. All these had three votes each in the decisions of the assembly. Of the remaining towns, some had two votes each, others only one. So productive of peace and good order was this constitution, that it was left in full operation by the Romans after they had subdued the country. Finally, however, it became disordered and incompetent, and was abolished by the Emperor Claudius. According to Herodotus, the Lycians had derived their

customs partly from the Cretans, and partly from the Lycomedes Carians; but differed from these nations as well as from all others in assuming the name of their mothers and not of their fathers.

||
Lycon.

Recent discoveries have ascertained that the Lycians had an alphabet compounded of the Greek and some other character. Although possessing a language of their own, they seem also to have been intimate with that of the Greek, a circumstance that might be partly the result and partly the cause of their want of a national literature. The remains of their temples and richly ornamented tombs show, that in architecture and sculpture they were not far behind the Greeks.

At a very early period the Lycians seem to have waged a protracted warfare with the Solymi, the aborigines of the country; and to this struggle the legends of the Lycian hero Bellerophon, as related by Homer, bears reference. In the *Iliad* the Lycians are enumerated among the allies of the Trojans; and their two champions, Glaucus and Sarpedon, act a prominent part in the war. Strongly banded together by their excellent government, the towns of Lycia successfully repulsed the arms of Cræsus. Yet they were forced by Cyrus to submit to the yoke of the Persians, and are mentioned by Herodotus as contributing their contingent of fifty ships to the fleet of Xerxes. They succumbed after a slight resistance to the power of Alexander the Great; and after the dismemberment of the Macedonian empire, came successively under the sway of the Ptolemies, the Seleucidæ, and the Romans. Adopting the cause of Octavianus and Antony, they were subdued and severely taxed by Brutus. After the government of Lycia had been abolished by the Emperor Claudius, that country became part of the prefecture of Pamphylia. However, in the reign of Theodosius II., it was constituted a separate province. (See *A Journal written during an Excursion in Asia Minor*, London, 1839; and *An Account of Discoveries in Lycia, being a Journal kept during a Second Excursion in Asia Minor*, London, 1841, both by Sir C. Fellows.)

LYCOMEDES, king of the island Scyros, in the Ægean Sea, father of Deidamia, by whom Achilles had Pyrrhus or Neoptolemus. He was secretly entrusted with the care of young Achilles, whom his mother Thetis had disguised in female attire, to prevent him proceeding to the Trojan war, where she knew he must unavoidably perish (Apollodor. iii. 13, § 8; Sch. *ad Il.*, xix. 332). He treacherously slew Theseus to gain the favour of Menestheus, or dreading the influence of the strangers upon his own subjects (Pausan. i. 17, § 6).

LYCON, a philosopher of the school of Aristotle, was a native of Laodicea, in Phrygia. He was born B.C. 300, and died at the age of seventy-four, B.C. 226. Upon the death of Strato, Lycon became the head of the Aristotelian sect (B.C. 270), and taught the school at Athens which had been conducted successively by Aristotle, Theophrastus, and Strato, whom he succeeded. We are informed by Diogenes Laertius, in his life of this philosopher, that he was particularly successful in directing the studies of youth; and that he regarded corporal punishment as not only useless, but positively injurious, holding that youth ought to be directed by feelings of honour and shame, as a horse is by the spur and reins. His eloquence was full of mild persuasion, and so melodious, that his contemporaries prefixed the letter G to his name, making it Glycon, which signifies *sweetness*. He was much esteemed by Attalus and Eumenes I., kings of Pergamus; and Antiochus, King of Syria, did everything in his power to prevail on him to remain at his court. He conducted the school with great ability during upwards of forty-two years, and was succeeded by Aristo Ceus (Plut. *Mor.*, p. 605, B). The last will of Lycon is given by Diogenes, and exhibits a strong

Lycophron. proof of the kindness and goodness of his nature. It appears from Cicero (*Tusc. Disp.* iii. 32), that he wrote on the boundaries of good and evil. A work of his on the nature of animals is quoted by Apuleius.

LYCOPHRON, a Greek poet, was a native of Chalcis, a city in the island of Eubœa, and the son of Socles; but of his private history we are almost entirely ignorant. It is supposed that Lycophron began to be distinguished in the beginning of the reign of Philadelphus, B.C. 280, and continued to rise in reputation till B.C. 250, during the first years of the first Punic War, a period of thirty years. If we be correctly informed respecting the mode in which he acquired the friendship and favour of Ptolemy Philadelphus, who then held his court at Alexandria, it is not much to the credit of Lycophron. It is said that he owed it to the flattering compliments he contrived to convey to the prince through ingenious anagrams. Thus, from *Προλεμῖος*, he made *ἀπὸ μέλιτος* (of honey); in Arsinoë, the name of the queen, he found *ἰὸν ἑπας* (violet of Juno). Lycophron is included amongst those seven poets who from their number were called the Pleiad. They were all contemporary, and all graced the court of Philadelphus. Their names were Homerus, Sosithus, Lycophron, Alexander (*Ætolus*), Philiscus, Sosiphanes, or Dionysides, and *Æantides*. Lycophron was the author of sixty-four, or, according to others, of forty-six, tragedies (Tzetzes *ad Lyc.*, p. 270). Suidas gives the names of nineteen of them. They have all, however, disappeared, and the only fragment of them that has been preserved is a verse of four lines, quoted by Stobæus from his tragedy entitled *Pelopidæ*. The idea is beautiful, and is expressed with great simplicity. "The unhappy call upon death to relieve them while he is at a distance; but when the last moments of life approach, we are anxious to live. Man is never tired of life." Lycophron is also said to have been the author of satires. One of these, directed against Menedemus, in which he ridiculed the frugal table of this founder of the Eretrian school, has been particularly mentioned (*Athen.* x., p. 420; xi., p. 55). He also wrote some books on comedy; but the work which has been preserved, and for which he is best known, is entitled *Alexandra*, or *Cassandra*, from the daughter of Priam, who had two appellations, like her brother Paris. The poem consists of 1474 lines. Cassandra had acquired by a trick the power of prophecy from Apollo; but having refused to fulfil her engagement, the god prevented any credit being attached to her words, and caused her to be regarded as mad. She is shut up in a tower by Priam, that she may not alarm the city, and from the summit of the tower she observes the vessel depart which bore Paris to the shores of Greece. This spectacle excites her prophetic powers, and a servant who overhears her words repeats them to Priam. She commences by deploring the fate which she foresees must inevitably overtake her native city, and then proceeds to foretell the various calamities which will arise out of the Trojan War. She first recounts those which will befall Helen, her parents, brothers, and sisters; and then notices the fates of the different Grecian leaders, such as Ajax, Diomedes, Menelaus, Agamemnon, and Idomeneus. This causes her to refer to the numerous wars which had been carried on at various times between the inhabitants of Europe and Asia. She begins with the rape of Io and Europa, and, giving an historical sketch of the Argonauts, the Amazons, the Trojans, Midas, and Xerxes, she brings down her history to the time of Alexander the Great. Besides, there are many episodes scattered throughout the work, such as the Labours of Hercules, the Deluge of Deucalion, the Wanderings of *Æneas*, and the colony planted in Latium. This work of Lycophron is one of the most obscure which antiquity has handed down to us, and it appears that the author exerted all his ingenuity to render it so. He has succeeded principally by the employment

of unusual modes of syntax, of rare and obsolete words, of expressions far removed from the common dialect, of confused metaphors, and of periods so involved that the reader loses himself in a labyrinth of words. Of the many commentaries on the *Alexandra*, the only one extant is that by Tzetzes. The best edition is that of Potter (Oxford, 1697, 1702), in which the text is accompanied by the scholia of Tzetzes, the remarks of Canter and Meursius, and a valuable index. Reichard (Leips., 1788), rejecting the commentaries of Tzetzes, Meursius, and Potter, published the simple text and notes of Canter, adding a continued paraphrase like that which is found in the editions of the classics *ad usum Delphini*. The scholia have been published separately by Müller (3 vols. Leips., 1811). The best edition, with the smaller scholia, a paraphrase, Latin translation, and commentary, is that of L. Bachmann (Leips., 1830).

LYCURGUS, a celebrated lawgiver of Sparta, who established a constitution for his country which has ever been regarded as one of the most curious specimens of legislation that has been attempted to be imposed upon mankind; yet we have no certain information respecting Lycurgus, and even his very existence has been denied. It has been supposed by some that there were several of the same name, and, as in the case of Hercules, that the proceedings of all of them were ascribed to one individual. Believing in the existence of an individual of this name, we shall proceed to narrate those facts in his history respecting which writers are most fully agreed. He seems to have flourished about 884 B.C., if we follow the chronology of Eratosthenes, who placed him 108 years before the first Olympiad (Eratosth. *ap. Clem. Alex. Strom.* i., p. 336, ed. Colon.). He was the son of Eunomus, King of Sparta, and was of the race of the Heracidae. On the death of his father, Polydectes his brother succeeded, and reigned nine years, and on his death the general voice of the people called Lycurgus to the throne. As soon as it appeared that his brother's widow was pregnant, he declared that the kingdom must belong to her issue, provided it were male, and that he should consider himself only as regent till the result was known. The queen made a private offer to him that she would destroy the child if he would consent to marry her. Lycurgus, concealing the horror he felt for her wickedness, and wishing to prevent the execution of her intention, allowed her to imagine that he approved of her scheme. He prevailed on her to send the child to him as soon as it was born that he might see it destroyed, but, instead of acting as the queen had expected, he presented it to the people as their new-born king. Thus the reign of Lycurgus lasted only eight months. Though Lycurgus was much beloved by his fellow-citizens, still there were many who envied him, and more particularly the friends and relations of the queen-mother. He began to feel his position so uncomfortable, that he determined to leave his country till his nephew Charilaus should be of age. During his voluntary exile he visited the island of Crete, where he examined the forms of government established by Minos; he travelled through Asia Minor and Egypt, observing everywhere the peculiar laws of the country, and conversing with the most illustrious personages. It was during one of those journeys through the Ionian cities that he met with Homer's poems, and being charmed with the sound morality which pervaded them, no less than with the beauty of the poetry, he is said to have collected them into one volume, and to have transmitted the work to Sparta. After an absence of eighteen years, his countrymen prevailed on Lycurgus to return home, where he found the city a prey to anarchy, the authority of the magistrates disregarded, and everything tending to a dissolution of all the bonds of society. He had been so charmed with the form of government he had found established in Crete, that he resolved to introduce it into Sparta; but he did not succeed without much opposi-

Lycurgus
||
Lydgate.

tion, and exciting many popular tumults. It seems difficult to imagine how he contrived to obtain their consent, as the laws must have been particularly burdensome to those who had been hitherto accustomed to a different form of life. He violated all the rights of private property, and seizing upon the land, divided it into equal portions among the inhabitants. He at the same time stopped the currency of gold and silver, and allowed nothing but iron moneys. The inhabitants were obliged to eat at a public table, and he took care that their food should be of the most frugal kind. The children were educated together without regard to rank, and the chief object of their education was to make them obedient to command, to endure labour, to fight, and to conquer. After he had instituted these laws, he made the people swear to observe them till he should return, and left his country for ever. (For an account of the legislation of Lycurgus, see SPARTA.)

LYCURGUS, one of the most celebrated orators of Greece, was born at Athens about the year B.C. 400, and died about B.C. 323. He was son of Lycophron, and grandson of Lycurgus, one or other of whom was put to death by the Thirty Tyrants, B.C. 404 (Phot. *Cod.* cclxviii, p. 1483). In his early years he studied philosophy under Plato, and the political constitution of his country under Isocrates. At what period he entered upon public life is nowhere recorded, but we find him, B.C. 343, appointed, along with Demosthenes, one of the ambassadors to counteract the proceedings of Philip in different parts of Greece (Demosth. *Philipp.* iii, p. 129). So much confidence had his fellow-citizens in his integrity, that he continued to preside over the collection of the public revenue for twelve or fifteen years. After the defeat of the Greeks at the battle of Chæronea, B.C. 338, he brought Lysicles, the general of the Athenians on that occasion, to trial before the people, and procured his condemnation (Diodor. Sicul. xvi. 88). He restored the credit of comic exhibitions at the Lenæan festival, and enacted honours for the three great tragic poets (*Vita Decem Or.*, p. 841). Lycurgus was one of the orators demanded by Alexander after the destruction of Thebes, B.C. 335; but the Athenians refused to give him up (Plut. *Demosth.* c. 23; Arrian, *Exp.* i. 10). It would appear that Lycurgus died about the time of the exile of Demosthenes, B.C. 323, the year before that orator's death (*Vita Decem Or.*, p. 842). There were fifteen orations of Lycurgus extant in the time of Plutarch and Photius, but only one has been preserved (against Leocrates), which was delivered B.C. 330. It is published by Hauptmann (Leips., 1751), by Schulze (Bruns, 1789), by Osann (Jena, 1821), and, along with other fragments, by Bekker (Magdeb., 1821). The best editions are those of Baiter and Sauppe (Turici, 8vo, 1834), and E. Maetznar (Berlin, 8vo, 1836).

LYDGATE, JOHN, an English poet, one of the immediate successors of Chaucer, assumed as his surname the name of his native place in Suffolk. The date of his birth is unknown; but it has been ascertained that he entered the Benedictine Abbey of Bury St Edmunds, and was ordained a subdeacon in 1389, a deacon in 1393, and a priest in 1397. He had begun to write before the death of Chaucer in 1400; and, according to Warton, seems to have reached the acme of his fame in 1430. After a short attendance at the university of Oxford, he had travelled into France and Italy, and had acquired an intimacy with the language and literature of those countries. With his taste thus improved, he opened a school for the instruction of the sons of the nobility in the arts of composition, both prose and metrical. He died at some period before 1461. To his excellence as a poet, and his proficiency in polite learning, Lydgate added a knowledge of geometry, astronomy, and theology. His genius was as many-sided as his erudition. With equal facility he delineates the *London Lickpenny* and the *Luffe of our Lady*, the religious aus-

Lydia.

terity of St Austin and the heroic deeds of Guy of Warwick. "If a disguising was intended," says Warton, "by the Company of Goldsmiths, a mask before his majesty at Eltham, a May-game for the sheriffs and aldermen of London, a mumming before the lord mayor, a procession of pageants from the creation for the festival of Corpus Christi, or a carol for the coronation, Lydgate was consulted and gave the poetry." This ease in composition, however, was often purchased by a lameness in prosody, and a want of precision both in thought and expression. He has not the original invention and the vivid representation of his master Chaucer, whom he was so anxious to rival. Yet in many of his descriptions of scenery we find a melody of rhythm, and a sweetness of fancy, which entitle him to the name of an improver of English versification.

A complete catalogue of Lydgate's voluminous works is given in Ritson's *Bibliographia Poetica*. His principal poems are three. *The Fall of Princes*, printed by Pynson in 1494, is a paraphrase of a French translation of Boccaccio's *De Casibus Virorum*. The princes are introduced dramatically to narrate their own mishaps; and, accordingly, the poem was not inaptly styled in the first edition, *The Tragedies gathered by John Bochas of all such Princes as fell from their estates since the Creucion of Adam*, &c. His *Storie of Thebes*, first printed by Thynne in 1561, at the end of Chaucer's works, is an additional Canterbury tale, in which the classical story of the sons of Œdipus is told with all the circumstances and machinery of romance. In a similar manner is the Trojan War treated in his *Troye-Boke*, printed in 1513 by command of Henry VIII. This poem is professedly a translation or paraphrase of the *Historia Trojana* of Guido de Colonna. The *Minor Poems of Dan John Lydgate*, edited by Halliwell, were published by the Percy Society, 1840.

LYDIA, in *Ancient Geography*, a celebrated kingdom of Asia Minor. The ancient writers inform us that Lydia was first called *Mæonia*, or *Meonia*, from Meon, King of Phrygia and Lydia; and that it was known under no other denomination until the reign of Atys, when it began to be called *Lydia*, from his son Lydus. Though Lydia and Mæonia are by most authors indifferently used for one and the same country, yet they are sometimes distinguished; that part including Mount Tmolus, and watered by the Pactolus, being properly called *Mæonia*; and the other, situate upon the coast, *Lydia*. This distinction is observed by Homer, Callimachus, Dionysius, and other ancient writers. In after ages, when the Ionians, who had planted a colony on the coast of the Ægean Sea, began to gain influence, that part was called *Ionia*, and the name of *Lydia* given to the ancient Mæonia. Lydia, according to Pliny, Ptolemy, and other ancient geographers, was bounded by Mysia Major on the N., by Caria on the S., by Phrygia Major on the E., and by Ionia on the W., and was situate between the 37th and 39th degrees of N. latitude. But what the ancients style the kingdom of *Lydia* was not confined within these narrow boundaries; it extended from Halys to the Ægean Sea. Pliny's description includes *Æolia*, situate between the Hæmus and the Caicus.

Some of the ancients conceive the Lydians to have been a mixed colony of Phrygians, Mysians, and Carians; but others, finding some conformity in religion and religious ceremonies between the Egyptians and Tuscans, who were a Lydian colony, conclude, without further evidence, that they were originally Egyptians. All we know for certain is, that the Lydians were a very ancient nation; and this is manifest from their fables; for Atys, Tantalus, Pelops, Niobe, and Arachne, are all said to have been the children of Lydus. Zanthus, in his *Lydiaca*, quoted by Stephanus, informs us, that the ancient city of Ascalon, one of the five satrapies of the Philistines, mentioned in the books of

Lydia. Joshua and the Judges, was built by one Ascalus, a Lydian, whom Achiamus, King of Lydia, had appointed to command a body of troops which he sent into Syria, we know not on what occasion. The Heraclidæ, or Kings of Lydia descended from Hercules, began to reign before the Trojan War, and had been preceded by a long line of sovereigns sprung from Atys, and hence styled *Atyadæ*—a strong proof of the antiquity of that kingdom.

The Lydians began very early to be governed by kings, whose authority seems to have been despotic, and the crown hereditary. We read of three distinct races of kings reigning over Lydia,—the *Atyadæ*, the *Heraclidæ*, and the *Mermnadæ*. The *Atyadæ* were so called from Atys the son of Cotys, and grandson of Manes, the first Lydian king. But the history of this family is obscure and fabulous. The *Atyadæ* were succeeded by the *Heraclidæ*, or the descendants of Hercules. This hero having, by the direction of the oracle, been sold as a slave to Omphale, Queen of Lydia, in order to expiate the murder of Iphitus, had by one of her slaves, during his captivity, a son named Cleolaus, whose grandson Argon was the first of the *Heraclidæ* who ascended the throne of Lydia. This race is said to have reigned 505 years, the son succeeding the father for twenty-two generations. They began to reign about the time of the Trojan War. The last of the family was the unhappy Candaules, who lost both his life and kingdom by his imprudence. Of this event an account is given by Herodotus. Candaules had a wife whom he passionately loved, and believed to be the most beautiful of her sex. He extolled her charms to Gyges, his favourite, whom he used to intrust with his most important affairs; and to convince him the more of her beauty, resolved to show her to him quite undressed. Enraged at this wanton affront, she told Gyges that he must either by his death atone for the criminal action he had been guilty of, or put to death Candaules, the contriver of it, and receive both her and the kingdom of Lydia as his reward. Gyges chose the latter alternative, and having stabbed the king whilst he was asleep, married the queen, and took possession of the kingdom, in which he was confirmed by the response of the oracle of Delphi. Candaules is said to have purchased, for its weight in gold, a picture painted by Bularchas, representing a battle of the Magnates; a circumstance which shows how early the art of painting had begun to be appreciated in that country, Candaules having been contemporary with Romulus.

Gyges having thus possessed himself of the kingdom of Lydia, sent many rich and valuable presents to the oracle of Delphos, amongst which were six cups of gold, weighing thirty talents, and greatly esteemed for the workmanship. He made war upon Miletus and Smyrna, took the city of Colophon, and subdued the whole country of Troas. In his reign, and by his permission, the city of Abydus was built by the Milesians. Plutarch and other writers give a different account of his accession to the crown of Lydia, and inform us, without making any mention of the queen, that Gyges rebelled against Candaules, and slew him in an engagement. In Gyges commenced the third race called *Mermnadæ*, who were also, properly speaking, *Heraclidæ*, being descended from a son of Hercules by Omphale.

Gyges reigned thirty-eight years, and was succeeded on the throne by his son Ardyes, who possessed himself of Priene, and of Sardis the metropolis of Lydia, and after reigning forty-nine years, was succeeded by his son Sadyattes, who reigned twelve years, during most part of which he carried on war with the Milesians.

After him came his son Alyattes, who, for the space of five years, continued the war which his father had begun against the Milesians, ravaging their country, and about harvest-time yearly carrying away all their corn; when having on one occasion set fire to the corn in the fields,

the flames were carried by a violent wind, which happened at that time to blow, to the temple of Minerva at Assesus, and burned it down to the ground. Not long afterwards, Alyattes falling sick, sent to consult the oracle at Delphos; but the god refused to return any answer until the king should rebuild the temple of Minerva at Assesus. Alyattes, thus warned, despatched ambassadors to Miletus, enjoining them to conclude a truce with the Milesians until the temple should be rebuilt. On the arrival of the ambassadors, Thrasybulus, then King of Miletus, having commanded all the corn which was at that time in the city to be brought into the market-place, ordered the citizens to banquet in public, and to revel as if the city were plentifully stored with all manner of provisions. This stratagem Thrasybulus practised that the ambassadors, seeing such quantities of corn, and the people everywhere diverting themselves, might acquaint their master with his affluence, and thus divert him from pursuing the war. As Thrasybulus had intended, so it happened. Alyattes, who believed the Milesians greatly distressed for provisions, receiving a different account from his ambassadors, changed the truce into a lasting peace, and ever afterwards lived in amity and friendship with Thrasybulus and the Milesians.

After a reign of fifty-seven years, he was succeeded by his son Cræsus, whose uninterrupted prosperity, in the first years of his reign, far eclipsed the glory of his predecessors. He was the first who made war on the Ephesians, whose city he besieged and took, notwithstanding their consecrating it to Diana, and their fastening the walls by a rope to her temple, which was seven stadia from the city. After the reduction of Ephesus, he, under various pretences, attacked the Ionians and Æolians, obliging them, and all the other Greek states of Asia, to pay him an annual tribute. Having met with such extraordinary success by land, the Lydian prince determined to render his power equally conspicuous by sea. For this purpose he had serious thoughts of equipping a fleet, with which he purposed to invade and conquer the Grecian islands directly opposite to his dominions. But this design, which, considering the slow progress of maritime power amongst the nations most diligent in attaining it, would probably have failed of success, was prevented by the advice of a philosophical traveller, conveyed in such a lively turn of wit as easily changed the resolution of the king. Bias of Priene, in Ionia (some say Pittacus of Mitylene, in the Isle of Lesbos), whilst he travelled, after the Grecian custom, from curiosity and a love of knowledge, was presented to Cræsus at the Lydian court; and being asked by that prince what news he brought from Greece, answered with a republican freedom, that the islanders had collected powerful squadrons of cavalry with an intention of invading Lydia. "May the gods grant," said Cræsus, "that the Greeks, who are unacquainted with horsemanship, should attack the disciplined valour of the Lydian cavalry; there would speedily be an end to the contest." "In the same manner," replied Bias, "as if the Lydians, who are totally unexperienced in naval affairs, should invade the Grecians by sea." Struck by the acuteness of this unexpected observation, Cræsus desisted from his intended expedition against the islands; and, instead of employing new means for extending his conquests, determined peaceably to enjoy the laurels he had won, and to display the grandeur he had attained. But his happiness was soon afterwards allayed by the death of his favourite son Atys, who was unfortunately killed in the chase of a wild boar. This loss rendered him disconsolate for two years, and reduced him to a state of inaction till the conquests of Cyrus and the growing power of the Persians roused up his martial spirit, and diverted his mind to other thoughts.

Cræsus apprehending that the success which had attended Cyrus in all his undertakings might at last prove dangerous

Lydia.

Lynn.

nine assassinations in a single year in a town of Virginia with 3000 inhabitants. There have been frequent instances, especially in the southern states of the Union, of violent outbreaks of popular revenge, under the form of lynch law, against the advocates, real or supposed, of the abolition of slavery. (See Miss Martineau's *Society in America*.)

LYNN, or LYNN-REGIS, a seaport and parliamentary and municipal borough of England, in the county of Norfolk, is situate on the Ouse, about 40 miles W.N.W. from Norwich. The town is well lighted and paved, has three principal streets running parallel to the river, and is traversed by four small streams called "fleets." It has an old guildhall, an exchange and custom-house, a borough jail, a theatre, several schools, a young men's institute, hospitals, alms-houses, and a market-cross 70 feet in height. The principal market-place is spacious, and inclosed by good houses. St Margaret's church, a cruciform structure, founded in 1100 is partly of the early English style, and is especially rich in monumental brasses. The chapel of St Nicholas, built by Edward III., has a fine timber roof and a rich south porch. There are also the church of All Saints, St John's church, and several meeting-houses of Independents, Baptists, and Wesleyan Methodists. Thoresby's grammar-school, founded about 1500, has six exhibitions for Cambridge University. Ship-building, rope-making, shrimp and other fisheries, engage a great part of the population. The harbour of Lynn is capable of containing about 300 sail; but the long channel which connects it with the sea is often obstructed by shifting sands. Agricultural produce, and a fine white sand used in the manufacture of glass, are exported. The imports are chiefly wine from France, Spain, and Portugal; and hemp, wood, and flax from the Baltic. The number and tonnage of vessels registered at Lynn on 31st December 1855 were as follows:—Sailing vessels of and under 50 tons, 56; tonnage, 1832: above 50 tons, 110; tonnage, 16,253. Steam-vessels of and under 50 tons, 2; tonnage, 26; above 50 tons, 1; tonnage, 256. In the coasting trade, during 1855, there entered the port 1260 sailing vessels, of 109,898 tons; and 49 steam-vessels, of 5433 tons: and there cleared out 397 sailing vessels, of 23,100 tons; and 49 steam-vessels, of 5433 tons. In the colonial trade, during the same year, there cleared out 1 British vessel of 225 tons. For 1855 the reports concerning the foreign trade were,—inwards, 61 British vessels, 7003 tonnage; 85 foreign vessels, 6084 tonnage;—outwards, 25 British vessels, 2250 tonnage; 13 foreign vessels, 990 tonnage. Lynn is supposed to have existed in the time of the Romans. Formerly a fief of the bishops of Norwich, and called, on that account, *Lynn Episcopi*, it was emancipated by Henry VIII., and at the same time received its present name. Remains of the old fosse and wall are still seen. On the east side of the town stands Red Mount chapel, octagonal without, but cruciform within. There is also the beautiful hexagonal steeple of Greyfriars, 90 feet in height, supported by groined arches, and serving as a landmark to ships entering the harbour. Lynn is governed by 1 mayor, 6 aldermen, and 18 councillors. Ever since the time of Edward I., it has returned 2 members to parliament. Pop. (1851) 19,355.

LYNN, a seaport-town of the United States of North America, Essex county, Massachusetts, on the N.E. shore of Massachusetts Bay, near the mouth of Saugus River, 9 miles N.E. of Boston; N. Lat. 42. 28., W. Long. 70. 56. It is regularly laid out on a gentle eminence rising gradually from the shore, and is environed by beautifully wooded heights. The streets are generally long, and many of them are ornamented with rows of trees. The chief public buildings are,—the town-house, the lyceum, and many churches and schools. There is also a natural history institution, with a library and museum. Lynn has be-

come famous as the principal seat of the boot and shoe manufacture in New England, which has increased here very rapidly. During the year ending June 1855, there were made in Lynn 3,274,893 pairs of boots, and 6,000,700 pairs of shoes; the manufacture employing 6476 females, and 4545 males, or nearly three-fourths of the whole population. Lynn and its neighbourhood are much resorted to by sea-bathers and pleasure parties from Boston. It was founded in 1629, and incorporated as a city in 1850. Pop. (1845) 9367, (1855) 15,800.

LYON KING-AT-ARMS. This office is of great antiquity and respect in Scotland; and although the precise date of its institution is unknown, yet it must have been as early as the introduction of armorial figures as hereditary marks of gentility and distinction into this country, which was in the twelfth century. (For a history and description of the Lord Lyon's court, see the article *HERALD*.) The regalia of this officer are,—a crown of gold, with a crimson velvet cap, a gold tassel, and an ermine lining; a velvet robe reaching to his feet, with the arms of the kingdom embroidered thereon, before and behind, in the proper tinctures; a triple row of gold chains round his neck, with an oval gold medal pendant thereto, on one side of which is the royal bearing, and on the other St Andrew with his cross enamelled in proper colours, and a baton of gold enamelled green, powdered with the badges of the kingdom. On solemn occasions the Lord Lyon wears the regalia above described; at all other times he wears the oval gold medal or badge on his breast, suspended by a broad green ribbon.

LYON, GEORGE FRANCIS, was born at Chichester, in Sussex, in 1795. He was scarcely thirteen when he entered the navy, and in 1816 he joined Lord Exmouth's squadron for the bombardment of Algiers. At Malta, Lyon was prevailed upon by the traveller Ritchie to accompany him on an expedition to North Africa. Lyon reached the port of Tripoli on the 25th November 1818, and spent the greater part of the two following years in making explorations in Soudan, the course of the Niger, &c. Ritchie died, and Lyon was compelled to return to England on the 29th July 1820, when he published an account of his expedition. Next year Lyon got the command of the *Hecla*, and in concert with Captain Parry of the *Fury*, set out on a voyage of discovery to Hudson's Bay. They returned in 1823; and an account of this expedition was published at London in 1824. Lyon made an unsuccessful voyage next with the *Griper* to Repulse Bay, of which he gave an account in 1825. The rest of his life was spent chiefly in a survey of the mines of Mexico. He died in 1832.

LYONNET, PETER, an ingenious naturalist, descended from an ancient family of Lorraine, was born at Maestricht in 1707. At school he showed a singular aptitude for languages, and in a short time became an adept in Latin, Greek, Hebrew, French, Italian, Spanish, German, and English. His father, a minister of the French church at Heusden, had designed him for a clergyman, and accordingly with that view Lyonnet entered the university of Leyden. There, in addition to the prescribed subjects, he studied anatomy, music, drawing, and sculpture. Abandoning all intention of entering the church, he soon afterwards applied himself to law; and after he had graduated at Utrecht, practised for some time at the Hague. He then began to study deciphering, and in a short time was appointed secretary of ciphers and translator of Latin and French to the states-general of the United Provinces. The time not engrossed by these offices was employed by Lyonnet in amassing materials and executing plates for a description which he intended to write of the insects found in the vicinity of the Hague. Abandoning this project, however, he contented himself with contributing some of his materials to a French translation of Lesser's work on

Arms
||
Lyonnet.

Lyons. the *Theology of Insects*, published at the Hague in 1742. This translation, along with Lyonnet's remarks, was reprinted at Paris in 1745, by the celebrated Reaumur. Meanwhile, in 1744, he had designed and engraved the plates for Trembley's work on the fresh-water polypus. He was chosen a fellow of the Royal Society of London in 1748, and a member of the Society of Sciences at Haarlem in 1753. In 1757 he was elected a member of the Royal Academy of Sciences at Rome, through the influence of the celebrated M. Le Cat, its perpetual secretary. The publication in 1760 of his chief work, *Traité Anatomique de la Chénille qui ronge le bois de Saule*, spread his reputation, and he was honoured with diplomas of membership from the Royal Academy of Sciences of Berlin in 1760, from the Imperial Academy of Naturalists in 1761, and from the Imperial Academy of Sciences at St Petersburg in 1762. A description and plate of the instruments he had used in dissecting the *chénille* were published by Lyonnet in the *Transactions* of the Society of Sciences at Haarlem, and afterwards in French at the beginning of his *Traité Anatomique*. He had intended to pursue this track of inquiry, and to examine the animal above named in its various stages of development; but at the age of sixty an accident impaired his eyesight, and thus defeated his cherished plan. The last fifteen or twenty years of his life were spent in adding to his valuable collection of horns and shells a choice cabinet of more than 560 paintings. Lyonnet died at the Hague in 1789.

LYONS (French *Lyon*, ancient *Lugdunum*), the capital of the French department of Rhône, and, till recently, ranking in point of population and commercial importance as the second city of the empire; but the last census returns show that in the former of these respects it has been exceeded by Marseilles. It is situate at the junction of the Saône with the Rhône, and on the Paris and Marseilles Railway, 316 miles from the former, and 218 from the latter city; N. Lat. 45. 45. 45., E. Long. 4. 49. 33.; elevation above the level of the sea, 963 feet. The rivers Rhône and Saône being both navigable, it enjoys great facilities for trade; but it is as a manufacturing city that it is chiefly celebrated, and in this respect it is justly entitled to the name of the French Manchester. The staple articles of manufacture are silk stuffs of all descriptions, and which for richness and beauty are unequalled. In this manufacture about 100,000 of the population are either actively or indirectly concerned. There are no exact statistics of the silk manufacture at Lyons; but the following extract from a letter by the president of the chamber of commerce at Lyons, dated December 19, 1853, is said to give very nearly the exact results:—"During the present year and the two preceding, the manufacturers of silk at Lyons have employed about 60,000 machines (*metiers*), scattered over a district of about 40 miles. These machines have consumed about 2,500,000 kilogrammes of silk (5,500,000 lb.), valued at 160,000,000 francs (L.6,400,000); and the manufactured stuffs at 250,000,000 francs (L.10,000,000). It is estimated that the home consumption amounts to one-fourth or one-third of that quantity. The balance is exported to all parts of the civilized world; but by far the largest foreign market is found in the United States." The silk manufacture in Lyons is not carried on in large factories, but on the domestic system, in the dwellings of the master-weavers, each of which has usually from two to six or eight looms, which, with their fittings, are generally his own property. Himself and as many of his family as can work are employed on these looms, and frequently also one or more *compagnons*, or journeymen. The number of master-weavers in the city and suburbs is estimated to be about 9000. The silk merchants, of whom there are about 600 in Lyons, supply the silk and patterns to the owners of looms, who are entrusted with the task of producing

the web in a finished state. The weaving population, though earning comparatively good wages, are an ignorant and degraded race, living in a disgracefully filthy state, and showing little desire to improve their condition. Few of the journeymen ever raise themselves to be master-weavers. The silk manufacture was established here by Italian refugees in the middle of the fifteenth century. It was nearly ruined by the revocation of the edict of Nantes, which dispersed most of its best workmen to Spitalfields, Amsterdam, Crefeld, and other places. Lyons has numerous dye-works, printing establishments, foundries, glass-works, potteries, tanyards, breweries, chemical works, boat-building yards, &c., but these are all insignificant compared with its chief branch of industry. The commerce carried on by means of the rivers is very considerable. The town is built principally on the tongue of land, or peninsula, between the Rhône and Saône, each of which is crossed by eight or nine bridges communicating with extensive suburbs lying to the E. and W. The old portion of Lyons consists chiefly of narrow, crooked, and dirty streets, rendered dark and gloomy by the great height of the houses on each side, which are generally seven or eight storeys high. About three-fourths of a century ago, the point of confluence of the two rivers was removed about a mile farther S., and on the additional territory thus acquired the suburb of Perrache was formed. This has been laid out on a regular plan, and now contains many elegant streets and some very agreeable promenades. The suburb of La Croix Rousse, to the N. of the town, and that of Fourvières, on the right bank of the Saône, are chiefly inhabited by silk weavers. Those of Brotteaux and Guillotière are on the left bank of the Rhône. The best view of the town and neighbourhood is obtained from the summit of the steep hill of Fourvières, on the right bank of the Saône. The fortifications of Lyons consist of eighteen detached forts, arranged in a circle of 12½ miles round the town, crowning the heights of St Croix and Fourvières, and of Croix Rousse, above the suburb of that name, and including in its circuit the suburbs of Brotteaux and Guillotière. These fortifications are required more to quell insurrections among the inhabitants than to withstand attacks from without. In 1831, 1834, and 1837, formidable riots took place, in which many lives were lost. Both banks of the Saône and the left bank of the Rhône are lined with quays, some of which are planted with trees, and afford very agreeable promenades.

Of its numerous squares, the finest is the Place Bellecour, one of the largest in Europe, covering 15 acres, and planted with lime trees. In the centre is a bronze equestrian statue of Louis XIV. The Hôtel de Ville and the Museum, or *Palais des Beaux Arts*, form two sides of the square called *Place des Terreaux*. The former building, said to be the finest of its kind in France, was erected between 1646 and 1655. Its front is nearly 160 feet in width, flanked with a square tower and dome at either end, and in the centre is a clock tower, surmounted by a cupola, which rises to the height of 157 feet. The depth of the building is 383 yards. The *Palais des Beaux Arts*, formerly the Benedictine convent of St Pierre, consists of four large piles of building, inclosing a square court, and containing museums of antiquities and natural history, a picture gallery, schools of drawing and natural history, &c. The public library is the best provincial collection in France, containing about 80,000 printed volumes and a large collection of MSS. The cathedral of St Jean, on the right bank of the Saône, was begun in the seventh century, but not completed till the reign of Louis XI. It is a Gothic edifice, and has four towers, two of which flank the west front, while the other two, shorter but more massive, form the transepts. The church of Notre Dame stands on the summit of the hill of Fourvières, and is said to occupy the site of

Lyons.

Poetry.

the *Forum Vetus*, built by Trajan. Numerous Roman remains have been discovered on the hill, the principal being an amphitheatre and some fine arches of an aqueduct. The Hôtel Dieu, on the quay, facing the Rhône, is one of the most ancient establishments of the kind in France, having been founded by Childebert and his queen in the beginning of the sixth century. The present building was erected by Soufflot, and receives annually about 12,000 patients.

Lyons is the seat of an archbishop; and has a court of appeal, tribunals of primary instance and commerce, a council of *prud'hommes*, a mint, a university college, having faculties of theology, science, and literature, a school of medicine and pharmacy, a lyceum, a school of arts (*Institution de la Martinière*) for the gratuitous instruction of sons of artisans, a veterinary school, school of artillery, military gymnasium, deaf-and-dumb institution, and a botanic garden.

In the revolution of 1793, the people of Lyons having declared against the revolutionary party, the city was taken by the conventional army after a siege of upwards of two months, and almost reduced to ruins. It suffered severely from the inundations of its two rivers in June 1856. Pop. (1851) 156,169.

LYONS, *Gulf of* (the ancient *Gallicus Sinus*), an extensive bay of the Mediterranean Sea, formed by the southern coast of France, between the Pyrenean range on the W., and a headland near Toulon on the E. It extends 145 miles from one extremity to the other, and washes the shores of the six departments of Pyrenees-Orientales, Aude, Hérault, Bouches-du-Rhône, and part of Var. The principal rivers that enter it are,—the Rhône, the Aude, and Tet; and the chief towns on its coast-line are,—Marseille, Cette, and Port Vendres. Its shores in many parts are broken by long lagoons and low islands.

LYRE (Gr. λύρα), the generic name for an ancient musical instrument, varying in form and in the number of its strings, these being made to vibrate by twitching with the fingers, or with a plectrum held in the right hand. It is needless here to enter upon the fabled accounts of the origin of the Greek lyre, and its improvements. As to the manner of playing upon it, and bringing out its resources, ancient writers are silent. That the ancient lyre, even with very few strings, was capable of producing a great variety of sounds differing in pitch, by skilful *stopping* of the strings, seems certain; and this view of the matter was published at Parma, in 1798, by Vincenzo Requeno, in his *Saggi sul Ristabilimento dell' arte armonica de' Greci e Romani Cantori*. His words are:—"È un insigne pregiudizio di Burney e di quanti scrissero della Greca musica prima di lui lo stimare di scarsi suoni le cetre, e le lire di pochi corde. I Greci tastarono le corde, benchè i loro stromenti non avessero il manico. Alcune lire de' Greci mostrano nelle pitture dell' Ercolano uno tavoletta quadra, per la quale passavano quattro corde, e che, scorrendo per le medesime, alzava o calava il tuono; in altre lire s' intrecciavano rette le dita per mezzo delle quattro corde, e così si tastavano. Altri stromenti si tastavano in altre maniere, come a suo luogo dimostreremo" (tomo 1^{mo}. pp. 337-8). The writer of this article quoted the above passage in his paper, "Memoirs of Music," published in the *New Edinburgh Review*, April 1822. Since then two writers have claimed as a discovery what is really due to Requeno, of whom they take no notice. That lyres, or similar instruments, were known to the ancient Egyptians and to the Hebrews, seems certain; and that large harps were known to the former is proved beyond doubt by those paintings in the tombs at Thebes, drawings of which were published in the great French work, *Description de l'Égypte*, &c. (G. F. G.).

LYRIC POETRY was such as the ancients sung to the lyre or harp. It was originally employed in celebrating the praises of gods and heroes, and its characteristic was

sweetness. The author or inventor of it is, however, unknown. It was much cultivated by the Greeks; and Horace was the first who attempted it in the Latin language. Anacreon, Alcæus, Stesichorus, Sappho, and Horace, were the most celebrated lyric poets of antiquity. (See POETRY.)

LYSIAS, one of the most celebrated of the Greek orators, was born at Athens 458 B.C., and died, at the age of eighty, B.C. 378. He was the contemporary of some of the greatest men that Athens ever produced—of Thucydides and Xenophon, of Euripides and Sophocles. He was the son of Cephalus, a Syracusan, and is himself sometimes said to have been a native of this city; but he was born at Athens, whither his father was induced to emigrate by the advice of his friend Pericles. Cephalus was distinguished both for his great riches and for his virtues. It was at his house that Plato placed the scene of the most celebrated of his works, his *Dialogues on the Republic*. Cephalus no doubt procured the best masters to forward the education of his son; but Lysias left Athens at a very early age (B.C. 443), and proceeded to Thurium, in the south of Italy, to which place the Athenians were sending a colony. He was accompanied by the two celebrated historians Herodotus and Thucydides, and remained there for many years, during which time he is said to have studied the art of eloquence under two Syracusans, Tisias and Nisias. After the unsuccessful expedition of the Athenians to Sicily (B.C. 413), it would appear that Thurium, with their other dependencies in Magna Græcia, refused to submit any longer to Athenian supremacy. All those who remained well affected towards the parent state were obliged to fly, and Lysias on that occasion (B.C. 411) returned with his brother Polemarchus to Athens. Here he employed himself in commercial pursuits, and we are told that the two brothers employed 120 slaves in the manufacture of shields. We do not hear that he took any active part in the stormy politics of Athens, now approaching the conclusion of her war with Sparta. Athens fell into the hands of Lysander, and thirty tyrants were appointed to administer the affairs of the city. The patriotism and riches of Polemarchus and of his brother Lysias marked them out as fit objects for persecution to the tyrants. Polemarchus was put to death, and Lysias with great difficulty saved his life by flying to Megara (B.C. 404). Here he engaged in the conspiracy to restore the independence of his country, and is said to have furnished three hundred men at his own expense to assist Thrasybulus. The tyrants were expelled, and Lysias returned to Athens (B.C. 403), where he commenced his new career as an orator. It does not appear that he was much employed in the assemblies of the people, but that he confined himself principally to writing *accusations* or *defences*, at the desire of such persons as had occasion to impeach the conduct of others, or to defend their own. As a reward for his services, Thrasybulus proposed to the people that he should be admitted to the freedom of the state; but Archinus procured its rejection, because the proposal had not been made first to the senate, as the law required. Plutarch states that there were extant in his time no less than 475 orations ascribed to Lysias, of which only 235 were genuine, according to Dionysius. We are likewise told that he composed institutions of oratory, epistles, and panegyrics; but of all these writings only thirty-four orations have come down to us, some of which are in an imperfect state. The pleadings of Lysias contain a curious detail of the domestic manners and internal economy of the Greeks. Dionysius of Halicarnassus has written a critique on the works and style of Lysias; and, according to him, the orator was particularly distinguished for simplicity and precision, as well as for the fidelity with which he depicted the manners of the age. Quintilian compares him to a clear and pure rivulet rather than to a majestic river; whilst Cicero considers him as the model of a perfect

Lysias.

Lysimachus.

orator. The earliest edition of the orations of Lysias is that of Aldus, 1513; but the best is that of Taylor, Gr. and Lat., London, 1739; and of Reiske, Leipsic, 1772. The latest edition is by Foertsch, Leips. 1829; who has also published separately, *Observationes Criticæ in Lysiae Orationes*, Leips. 1829. See also Franzius, *Dissertatio inaug. de Lysia oratore Attico-Græce scripta*, Norimb. 1828. There is an English translation of the *Orations* by Gillies, London, 1778. Compare L. Hoelscher, *De Lysiae Oratoris Vita et Dictione*, Berlin, 8vo, 1837; Westermann, *Gesch. der Griech. Beredsamkeit*.

LYSIMACHUS, one of the generals of Alexander, was son of Agathocles, one of the king's body-guard, but of noble descent. He appears to have been one of the noblest characters that the age of Alexander, so fertile in great men, produced. He was the pupil of the philosopher Callisthenes, who attended Alexander in his expedition; and when the king ordered Callisthenes to be put to death by the most cruel tortures, Lysimachus enabled his friend to escape by furnishing him with poison. It might have been expected that Alexander would have admired such conduct, but it was far otherwise. He ordered Lysimachus to be exposed to the fury of a lion, and that he should suffer a death somewhat resembling that which had been intended for his friend. The bravery of Lysimachus saved him: wrapping his cloak round his arm, he pushed it into the throat of the lion, and laid it dead at his feet. Alexander forgave him, and attached him more particularly to his own person. This story, which is told by Justin (xv. 3), Pliny (viii. 16), and Seneca (*De Ira*, 3, 17, et *De Clem.* 1, 25), is called fabulous by Curtius (viii. 1, 22), and is said to have originated from the circumstance of Lysimachus having been attacked by a lion in the forests of Syria, and having killed it without assistance. From this moment Alexander treated Lysimachus as his friend, and was so fond of him, that having accidentally wounded him on the forehead as he was dismounting, he took off his diadem and bound up his head with his own hands; presaging, as Justin remarks, the royal rank to which he would afterwards attain. History is then silent respecting Lysimachus till the death of Alexander (B.C. 323), when we find him receiving, as his share of the kingdom, Thrace, and the countries placed along the coast of the Euxine (Justin, xiii. 4). But Seuthes occupied Thrace with a powerful army, and it was found necessary to conquer him before he could take possession of the kingdom. In this he was successful, and also in repressing a rebellion which had broken out at Callatia, on the coast of the Black Sea (Diodor. xviii. 14; xix. 73). No sooner did he feel secure of his dominions, however, than he began to attack the Odrysæ, Getæ, and other nations around; but he was defeated and taken prisoner, according to some historians, though, according to others, this was only the fate of his son. His daughter was given in marriage to the king of the country for releasing the captive (Pausan. i. ix.). The ambition of Antigonus began to alarm the other successors of Alexander, and a league was entered into by Ptolemy, Cassander, and Lysimachus, to reduce his power within due bounds. The war was carried on with various success for several years. Lysimachus proceeded to Asia (B.C. 302) to attack Antigonus, who was then at Antigonea in Syria, and in his passage subdued Phrygia, Lydia, and other districts, taking possession of many strong fortresses, where Antigonus had collected much treasure. He was joined by Seleucus, who arrived from Babylon with a considerable body of troops, and a decisive battle was fought (B.C. 301) at Ipsus, where Antigonus was defeated and killed (Justin, xv. 4). In addition to Thrace, Lysimachus obtained Bithynia, and some countries along the Hellespont. Yet Demetrius, son of Antigonus, did not lose courage, but made constant attempts to recover his dominions. A league was formed

VOL. XIII.

against him by Lysimachus and Pyrrhus King of Epirus, and he was driven from the greater part of Macedonia; but the two allies afterwards disagreed, and Pyrrhus having been defeated, Lysimachus assumed the title of King of Macedonia, B.C. 286. In his latter years he put to death his son Agathocles, at the suggestion of his second wife, who was afraid that she herself and her children would fall into the hands of Agathocles on the death of Lysimachus. Seleucus, taking advantage of the odium which this act brought upon him, attacked Lysimachus, and having given him battle, Lysimachus was killed, B.C. 281 (Pausan. i. x.; Justin, xvii. 1, 2).

LYSIPPUS, a celebrated Greek statuary, of the city of Sicyon, in the Peloponnesus, flourished about 324 B.C. He was at first a worker in brass, but afterwards devoted himself to statuary, studying nature, by the advice of Eupompus, rather than following the manner of any master. He excelled all those who had preceded him in the nicety of individual parts, and more particularly in the beauty of the hair. He lessened the size of the head, which had been exaggerated by the ancient sculptors, and made the body more slim so as to increase the appearance of the height. He used to say, that former sculptors represented men as they were, whilst he made them as they appeared to be. His reputation was such that his name was included in the famous edict published by Alexander, when he conferred on Apelles the sole right of painting his form, on Lysippus that of executing it in bronze, and on Pyrgoteles that of engraving it on precious stones. He is said (Plin. xxxiv. 7) to have produced 1500 works of art, any one of which was sufficient to stamp him as a man of talent. Of these we can only mention a few of the most celebrated. There was one at Rome, the removal of which from the baths of Agrippa to the palace of the emperor, by order of Tiberius, had nearly caused a sedition. The populace clamoured for its being replaced, and Tiberius did not deem it prudent to deny their request. It was a statue called Apoxyomenos, representing, as its name implies, a man scraping himself in the bath with a strigilis, an instrument to clean the body of the particles of sweat. He executed many statues of Alexander, representing him at different periods of his life; and he so managed that a slight bend of the head, for which Alexander was remarkable, became rather a beauty than a deformity. One of these statues was so much admired by Nero, that he caused it to be covered with gold, to the great grief of all true lovers of the art of sculpture. He executed a very fine bronze statue of Cupid with a bow, for the inhabitants of Thespis; also equestrian statues of twenty-five Macedonians who fell at the passage of the Granicus, and which Metellus caused to be transported to Rome. It has been supposed, though without any clear proof, that the celebrated horses of Venice formed part of this group. There is a statue of Hercules in the Palazzo Pitti at Florence, which bears his name, and has in every respect a strong resemblance to the Farnese Hercules, excepting the position of the legs (*Mus. Pio-Clem.* iii., p. 66). This likewise has made it be supposed that the statue of the Palazzo Pitti is a copy of the Hercules of Lysippus, and that the Farnese is an imitation, on which Glycon thought he might engrave his name, on account of the change he had made in its position. Lysippus had as pupils his own sons, Dahippus, Bedas, and Euthycrates (Plin. xxxiv. 8.) See Müller, *Handbuch der Archæologie der Kunst*, Breslau, 1830.

LYSONS, DANIEL, an eminent antiquarian and topographer, was rector of Rodmartin, in Gloucester, a living in which he succeeded his father in 1833. He was educated at Oxford, where he graduated in 1785. When a curate at Putney, he, in 1790, commenced his first topographical work, entitled *The Environs of London; being an Historical Account of the Towns, Villages, and Hamlets within 12*

miles of that Capital; interspersed with Biographical Anecdotes, 2 vols. 4to, 1810; a work which he supplemented about the same time by *An Historical Account of those Parishes of Middlesex not included in the Environs of London*. In conjunction with his brother Samuel, he undertook, in 1806, his great work, the *Magna Britannica*, being a precise topographical account of the several counties of Great Britain, 6 vols. 4to; an undertaking which he left unfinished. He published a small work at Gloucester in 1824, containing *A View of the Revenues of the Parochial Clergy of this Kingdom from the earliest times*, 8vo. Lysons wrote, besides, some sermons, which are not much known. As an accurate, laborious, and useful writer of topography, he occupies a very high place. He presented, previous to his death in 1834, 64 volumes of MS. collections for the *Magna Britannica* to the British Museum.

LYSONS, Samuel, the brother of the above, was born at Rodmartin, in Gloucester, in 1763. Originally educated for the bar, he ultimately relinquished that profession for antiquarian pursuits. He was an active and influential member of the Society of Antiquaries, and became, in 1803, keeper of the records in the Tower of London. In 1806 he joined his brother in the *Magna Britannica*; and published, in 1797, *Roman Remains discovered at Woodchester and Minchenhampton*; in 1801, his *Figures of Mosaic Pavements*; in 1802, his *Remains of Roman Antiquities at Bath*; in 1804, *Gloucester Antiquities*. He wrote also for the *Archæologia*. He died in 1819.

LYTTELTON, GEORGE, Lord, was born at Hagley, in Worcestershire, in 1709. Descended from the great Judge Littelton (see LYTTELTON, Thomas), he was the eldest son of Sir Thomas Lyttelton, who, during the interregnum of 1688 and the succeeding reign, appears as one of the ablest Whig debaters of the House of Commons. Mr Macaulay (*History of England*, vol. ii., p. 617) describes him as "versed in European politics, and gifted with a vehement and piercing logic, which had often, when, after a long sitting, the candles had been lighted, roused the languishing house, and decided the event of the debate." He received his education at Eton school, where he showed an early inclination to poetry. He was removed from thence to the university of Oxford, where he pursued his classical studies with uncommon avidity, and sketched the plan of his *Persian Letters*. In the year 1728 he set out on the tour of Europe; and, upon his arrival at Paris, accidentally became acquainted with the Honourable Mr Poyntz, then our minister at the court of Versailles, who employed him in many political negotiations, which he executed with great judgment and fidelity. In this early part of his life he wrote a poetical epistle to Dr Ayscough, and another to Mr Pope, both evincing singular taste and correctness.

After continuing a considerable time at Paris he visited Lyons, Geneva, Turin, Milan, Venice, and Genoa, and finally established himself at Rome, where he applied himself closely to the study of the fine arts. He soon afterwards returned to his native country, and was elected representative for the borough of Ockhampton, in Devonshire. In the year 1737 he was appointed principal secretary to his royal highness, Frederick Prince of Wales; and in the year

1742 he married Lucy, the daughter of Mr Hugh Fortescue of Filleigh, in the county of Devon, an excellent lady, whom he had the misfortune to lose in 1746. In 1744 he was appointed one of the lords commissioners of the Treasury; and, during his continuance in that station, constantly exerted his influence in rewarding merit and ability. He was the friend and patron of Fielding, Thomson, Mallet, Young, Hammond, West, Pope, and Voltaire. On the death of Thomson, who left his affairs in a very embarrassed condition, Mr Lyttelton took that poet's sister under his protection. He revised Thomson's unfinished tragedy of *Coriolanus*, and brought it out at the theatre royal, Covent Garden, with an affecting prologue of his own composition.

His valuable observations on the conversion and apostleship of St Paul were written in 1747, at the desire of Mr Gilbert West, in consequence of Mr Lyttelton's asserting, that besides all the proofs of the Christian religion which might be drawn from the prophecies of the Old Testament, from the necessary connection it has with the whole system of the Jewish religion, from the miracles of Christ, and from the evidence given of his resurrection by all the other apostles, he thought the conversion of St Paul alone, duly considered, was of itself a demonstration sufficient to prove that Christianity was a divine revelation. Dr Johnson characterizes this treatise as one "to which infidelity has never been able to fabricate a specious answer."

In 1754 he resigned his office of lord of the Treasury, and was made cofferer to his majesty's household, and sworn a member of the Privy Council; previously to which, he married a second time, Elizabeth, daughter of Field-Marshal Sir Robert Rich, from whom he was separated, by mutual consent, a few years after his marriage. After being appointed chancellor and under-treasurer of the Court of Exchequer, he was, by letters-patent dated the 19th of November 1757 (31st Geo. II.), created a peer of Great Britain, by the style and title of Lord Lyttelton, Baron of Frankley, in the county of Worcester. His parliamentary speeches showed sound judgment, ready eloquence, and inflexible integrity. During the last ten years he lived chiefly in retirement, devoting himself for the most part to literature. His *Dialogues of the Dead*, in which the morality of Fénelon and the spirit of Fontenelle are happily united, appeared in 1760. His *History of Henry II.*, a laborious and respectable production, the fruit of twenty years' labour, was published in 1764-67. He died in 1773.

A complete collection of his works was published after his decease by his nephew, Mr George Ayscough. (See *Memoirs and Correspondence of Lord Lyttelton*, 1734-1773, 2 vols. 8vo, London, 1845.)

LYTTELTON, Thomas, Lord, son of the above, and his successor in the peerage, was a young man of distinguished ability, who wasted his strength and his life by profligacy. A writer in the *Quarterly Review*, January 1852, endeavoured, with very considerable skill, and some degree of plausibility, to prove Thomas Lord Lyttelton to be the author of the *Letters of Junius*. There is a singular, and some say well-authenticated story, which relates that he was warned of his death three days previous to its occurrence in 1779, when only thirty-five years of age.

Lyttelton,
Thomas.

M.

M
Mably.

M is the thirteenth letter of the English alphabet, and a labial articulation of the liquid series, formed by the compression of the lips. It is called a semi-vowel, as the compression of the lips necessary to its articulation is accompanied with a humming sound through the nose, thus distinguishing it from the sound of the letter B, which in other respects so closely resembles it. M is uniform in sound, and scarcely ever silent. It is liable to interchange with the letters N, B, P, V, W, of which there are numerous examples in almost all languages. The letter M, or a symbol closely resembling it, was employed by the Romans as a numeral to denote a thousand, selected, as is generally supposed, from its being the initial of the word *mille*. With a dash over it (\bar{M}), it stands for a thousand times a thousand, or a million. For the use of M in ancient and modern abbreviations, see under ABBREVIATIONS. In astronomical tables, M stands for *meridian*, *meridional*, or *mid-day*. In medical prescriptions, M stands for *manipule*, or handful; for *misce*, or mix; for *mixture*, a mixture; and sometimes for *mensurâ*, by measure. In law, M is the brand of manslaughter, and is impressed on one who, after conviction, is admitted to the benefit of clergy.

MAAT, JOHN. (See BLANKOF.)

MABILLON, JEAN, a learned writer of France, was born at Perremonte, on the frontiers of Champagne, in the year 1632. He was educated in the university of Rheims, and afterwards entered into the abbey of the Benedictines of St Rémy. In the year 1663 he was appointed keeper of the treasures and monuments of France at St Denis. Next year he went to Paris, and proved serviceable to Father d'Acheri, in compiling his *Spicilegium*. Soon afterwards the congregation of Saint-Maur charged him with the edition of St Bernard, which he prepared with extraordinary diligence. In the year 1685 Louis XIV. sent him into Germany, to search the archives and libraries of the ancient abbeys for all that seemed calculated to illustrate the history of the church in general, and that of France in particular. Mabillon published an account of this journey in his *Iter Germanicum*. In the year 1685 he undertook a similar journey into Italy, and returned the year following with a very noble collection, of which he gave an account in his *Museum Italicum*. He also wrote an *Iter Burgundicum*, a work similar to those just mentioned. Next to Mabillon's *Correspondence*, one of his most interesting works is his *Reflexions sur les Prisons des Ordres Religieux*, in which he censures the cruelties of the monastic houses, and discloses the horrors of the famous subterranean dungeons, known as *Vade in Pace*, in which some were confined till they died. Another event in Mabillon's life worthy of being recorded, was the bold stand he made, in his *Traité des Études Monastiques*, in 1691, against the narrow bigotry of the Abbé de Rancé, who had forbidden the monks all scientific studies, and all reading, except the *Breviary*. Mabillon died at Paris in 1707. He was one of the most learned, liberal, and candid men of his age. His various works were collected and published after his death, under the title of *Ouvrages Posthumes de D. Jean Mabillon et D. Thierry Ruinart, Bénédictins de la Congregation de St Maur*, 3 vols. 4to. Paris, 1724.

MABLY, GABRIEL BONNOT DE, a French abbé, and brother of Condillac, was born at Grenoble on 14th March 1709. After receiving his education from the Jesuits in Lyons, he repaired to Paris, and, at the instance of his kinsman, the Cardinal De Tencin, entered the theological

college of St Sulpice. No sooner, however, had he reached the rank of sub-deacon, than he threw aside the studies proper to his order, and devoted all his time to profane literature. His first work, *Parallèle des Romains et des Français par Rapport au Gouvernement* (Paris, 1740), met with great success, and led to his being appointed secretary to the Cardinal De Tencin, at that time minister. In the discharge of his new office, Mably collected the greater part of that political information which he afterwards embodied in his *Droit Public de l'Europe fondé sur les Traités*, published in 1748, and reprinted with additions and improvements in 1754 and 1764. In 1743, after a series of secret negotiations, he concluded with the Prussian ambassador at Paris a treaty against Austria; and in 1746 he drew up the instructions for the French minister at the congress of Breda. Soon afterwards a quarrel with the cardinal induced Mably to retire into private life, and devote his time entirely to study. He died at Paris in 1785. His principal works are,—*Observations sur l'Histoire de la Grèce*, and *Observations sur les Romains*, 1751; *Principes des Negotiations*, La Haye, 1757; *Entretiens de Phocion sur le Rapport de la Morale et de la Politique*, 1763; *Observations sur l'Histoire de France*, Genève, 1765, reprinted, with notes by Guizot; *De la Legislation, ou Principes des Lois*, Amsterdam, 1776; *De la Manière d'écrire l'Histoire*, 1782; and *Observations sur le Gouvernement et les Lois des États-Unis d'Amérique*, 1784. His entire works were published by Abbé Brizard, in 15 vols. 8vo, 1794. Mably was an advocatè for equality in rank and community in property. Sparta, under the legislation of Lycurgus, was his model of a government.

MABUSE, or MAUBEUZE, JAN DE, an eminent painter, was born in 1499 at Maubeuze, in Hainault, and was originally called John Gossaert. After studying the great masters in Italy, he visited in succession Utrecht and Middleburg. His character was noted for the union of the lowest profligacy with the greatest enthusiasm for his art; and at this latter city he was imprisoned for some misdemeanour. He then repaired to England, and was employed to paint the children of Henry VIII. and several of the nobility. He is said to have died in 1562. The most famous picture of Mabuse is his altar-piece at Middleburg, representing the Descent from the Cross.

MACADAM, JOHN LOUDON, the introducer of macadamized road-making, was descended from an old and respectable family in Kirkcudbrightshire, and was born in Ayrshire, Scotland, in 1756. His plan of road improvement occurred to him when acting as trustee for a district of roads in Ayrshire, and was first carried into practice on the Bristol roads, of which he had been appointed surveyor-general in 1815. He explained his system fully in two works,—*A Practical Essay on the Scientific Repair and Preservation of Public Roads*, London, 1819; and *Remarks on the Present State of Road-making*, London, 1820. In 1827 he was appointed general surveyor of roads; and for the large sums which he expended while performing the duties of this office, he was afterwards compensated by two grants from government, amounting together to L.10,000. The honour of knighthood, which he declined, was conferred upon his son in 1834. Macadam died in 1836.

MACAO, a Portuguese settlement in China, on a small peninsula projecting from the S.E. end of the island of Hiangshan, or Macao, lying at the mouth of the Canton River, 80 miles S.S.E. of Canton, and 40 miles W. of Hong

Mabuse
||
Macao.

Macaronic Kong; N. Lat. 22. 12. 45., E. Long. 113. 35. The peninsula is $2\frac{1}{2}$ miles in length, by less than a mile in breadth, and is connected with the mainland by a low, narrow, and sandy isthmus. A barrier wall, with a gate and guard-house, extends across the isthmus, to exclude foreigners from the interior of the island. The town is built on the declivities round the semicircular harbour; the shore being lined by an embanked parade, behind which is a terrace of handsome houses. Behind this terrace lies the rest of the town, a curious intermixture of Chinese and European edifices. The chief buildings are,—the senate-house, the church and college of St Joseph, and the Portuguese governor's residence. The cave of Camoens, where that poet is said to have written a portion of his *Lusiad*, is picturesquely situate on the summit of a small hill on the margin of the inner harbour, and is much resorted to. The harbour is on the west side of the town, between it and the small island of Patera, but it has not sufficient depth of water to admit large vessels, which accordingly anchor in the roads on the other side of the peninsula, from 5 to 10 miles from the town. The Chinese regulations permit none but Portuguese and Spanish vessels to trade at the port, though vessels of other nations generally have little difficulty in obtaining the connivance of the Chinese officials to trade, and the Portuguese inhabitants are ready to lend their names for a trifling consideration. The town and harbour are protected by six forts. The Portuguese obtained this settlement in 1586, in return for services rendered by them against pirates that had infested the coast. It subsequently became the centre of a very extensive trade with China, Japan, the Philippines, and other eastern countries. It has, however, long sunk into insignificance, and now carries on very little trade. The Portuguese have a government and senate, but a Chinese mandarin has in reality the supreme power in the town. The Portuguese pay annual tribute, or ground rent, for their settlement. Pop. about 13,000, of whom above a half are Chinese.

MACARONIC, a ludicrous species of metrical composition, in which the words of a modern language are Latinized. The name is said to be derived from the Italian *maccheroni*, a mixture of paste, butter, spice, and grated cheese. The ostensible originator of this kind of verse was Theophilo Folengo, or, as he called himself, *Merlinus Coccaius*, a monk of Casino, in Italy, born in 1512. He wrote a burlesque Latin poem, chequered with Italian, Tuscan, and plebeian words, entitled *Phantasiæ Macaronicæ*; and in the *apologetica* to that work, the author describes this new species of poetry as follows:—"Ars ista poetica nuncupatur *Ars Macaronica*, a *Macaronibus* derivata: qui *Macarones* sunt quoddam pulmentum, farina, caseo, butyro compaginaturn, grossum, rude, et rusticum. Ideo *Macaronica* nil nisi grossedinem, ruditatem, et *Vocabulazzos* debet in se continere." Antonius de Arena of Avignon wrote in this style of verse as early, some say, as 1519. At all events, it soon after became highly fashionable in England, France, and Italy. John Skelton introduced it into England in the reign of Henry VII., and Rabelais, who so often refers to "Merlin the Cook" (Coccaie), first employed this style in French prose. Perhaps the best known form of macaronics in this country is the *Polemomidinia*, a Scottish burlesque in hexameters, by Drummond of Hawthornden. Some of the most successful macaronics of modern times have appeared in the pages of *Punch*.

MACARTHY ISLAND. See GAMBIA.

MACARTNEY, GEORGE (*Earl Macartney*), was the only son of a gentleman of Scottish descent, and was born in 1737 at the family estate of Lissanoure, near Belfast, in Ireland. After graduating at Trinity College, Dublin, he repaired to London in 1759, and became a student of the Inner Temple. In 1764 he was appointed envoy extra-

ordinary to the Empress of Russia. He returned in 1767, and after sitting for some time in the British parliament as member for Cockermouth, he became chief secretary for Ireland in 1769. On the expiry of this office in 1772 he was created Knight of the Bath. Appointed governor of Granada in 1775, Macartney was taken prisoner on the surrender of that island to the French in 1779, but was soon afterwards released. He became president of Madras in 1780, and would have been installed in the high office of governor-general of India had not his impaired health forced him to return to England in 1789. In 1792 he was appointed ambassador extraordinary to the court of Pekin. He was thus the first English envoy sent to China; and if he did not succeed in attaining the results expected, the fault was in nowise his. Immediately before his return in 1794, the title of baron, which had been conferred on him in 1776, was changed into that of Earl Macartney. He held the governorship of the Cape of Good Hope from 1796 until he was compelled by declining health to resign it in 1798. After living for some time in retirement, Lord Macartney died at Chiswick in 1806.

An account of his public life, with a selection from his unpublished writings, was published by his private secretary Barrow, in 2 vols. 4to, London, 1807. Sir George Staunton, who accompanied him to China as secretary, wrote an account of his Chinese embassy in 2 vols. 4to, London, 1797.

MACASSAR, or **MANKASSER**, called also by the Dutch *Vlaardingen*, a free seaport-town of the island of Celebes, on its S.W. peninsula, and capital of a cognominal government, is situate at the mouth of a river; S. Lat. 5. 9., E. Long. 119. 36. It is regularly laid out in rectangular streets, is surrounded by a wall, and environed by Malayan suburbs. The harbour, which has excellent anchorage, is protected by Fort Rotterdam. A considerable trade is carried on with China and Australia in the various productions of the country. The town was built by the Dutch on the site of a Malayan village, and was declared a free port in 1846. Pop. about 20,000. (See CELEBES.) The Straits of Macassar separate the islands of Celebes and Borneo, and extend about 300 miles from N. to S., with an average breadth of 126 miles, excepting at the northern extremity, where it contracts to about 60 miles. It is of very dangerous navigation, abounding with shoals, rocks, and rocky islands.

MACAULEY, CATHERINE, author of a *History of England*, was the daughter of John Sawbridge, Esq. of Olantigh, Kentshire, and was born there in 1733. In 1760 she was married to Dr George Macauley, a physician in London. Her principal work, entitled *The History of England from the Accession of James I. to that of the Brunswick Line*, began to be published in 1763, and was completed in eight volumes. This treatise, which went no farther than the Revolution, she supplemented, in 1778, by a series of letters, which brought the *History of England* as far down as the resignation of Walpole in 1742. Meantime the husband of Mrs Macauley had died; and in 1778 she became the wife of a young clergyman of the name of Graham. A favourer of republican opinions, she had carried on a correspondence with General Washington, and in 1785 she paid him a visit in America. She died in 1791. Besides her *History*, Mrs Macauley wrote *Remarks on Hobbes' Rudiments of Government and Society*, 8vo, 1767, republished, with additions, 4to, London, 1769; *Reply to Mr Burke's Pamphlet entitled "Thoughts on the Causes of the Present Discontent,"* 8vo, London, 1770; *A Modest Plea for the Property of Copyright*, 8vo, London, 1774; *Address to the People of England, Scotland, and Ireland, on the present Important Crisis of Affairs*, 8vo, Bath, 1775; *Treatise on the Immutability of Moral Truth*, 8vo, London, 1783,—republished, with additions, under the title, *Letters on Education*, 4to, London, 1790; and *Observations on the*

||
Maccabees.

MACBETH, a Scotch nobleman in the eleventh century, nearly allied to Duncan, King of Scotland, and the hero of Shakspeare's tragedy of *Macbeth*. The most authentic account of Macbeth represents him as the vassal of Thorfinn, a Norwegian prince, then master of the north of Scotland. Being called upon in the Norseman's absence to defend his territory against King Duncan, who attempted to regain it, Macbeth met the Scots king at Elgin, A.D. 1040, defeated his army, slew himself, and seized his crown. After various fruitless attempts to regain his crown, Malcolm Kenmore, son of the late king, succeeded, by the assistance of Siward, Earl of Northumberland, after a battle in which Macbeth was slain, in gaining possession of his father's throne. (See Skene's *Highlanders of Scotland*, vol. i., p. 115.)

MACCABEES, BOOKS OF (Gr. Μακκαβαίοι), a name usually supposed to have been cabalistically derived from מַכְבִּי (*Makkabi*), the initial letters of בְּאֵלִים יְהוָה מִי כִמּוֹהוּ ("who among the gods is like Jehovah?"), the motto on the Jewish standard in the war with the Syrians. The Books of Maccabees are the titles of certain Jewish histories, containing principally the details of the heroic exploits of the family of the Maccabees. (See JEWS.)

There were in all four books (to which some add a fifth) known to the ancients, of which three are still read in the Eastern, and two in the Western, Church. Of these the *third* is the first in order of time. We shall, however, to avoid confusion, speak of them in the order in which they are commonly enumerated.

The First Book of Maccabees (the second in order of time), contains a lucid and authentic history of the undertakings of Antiochus Epiphanes against the Jews, from the year B.C. 175 to the death of Simon Maccabæus, B.C. 135. This history is confessedly of great value. Although its brevity, observes De Wette (see 1 Macc. i. 6; viii. 7; xiii.), renders it in some instances unsatisfactory, defective, and uncritical, and occasionally extravagant, it is, upon the whole, entitled to credit, chronologically accurate, and advantageously distinguished above all other historical productions of this period (*Einleitung in die Apokryphe Bücher*, § 299). There is little question that this book was written in Hebrew, although the original is now lost. The Greek version abounds in Hebraisms and errors of translation. Origen gives it a Hebrew title; and Jerome says that he had seen the Hebrew original. Of the author nothing is known; but he must have been a Palestinian Jew, who wrote some considerable time after the death of Simon Maccabæus, and even of Hyrcanus, and made use of several written, although chiefly of traditionary, sources of information. At the same time, it is not impossible that the author was present at several of the events which he so graphically describes. The Greek text of the Alexandrine version is the original of all the others now extant. This text was that made use of by Josephus.

The Second Book of Maccabees (the third in order of time) is a work of very inferior character to the first. It is an abridgment of a more ancient work, written by a Jew named Jason, who lived at Cyrene, in Africa, comprising the principal transactions of the Jews which occurred during the reigns of Seleucus IV., Antiochus Epiphanes, and Antiochus Eupator. It partly goes over the same ground with the first book, but commences ten or twelve years earlier, and embraces in all a period of fifteen years. It does not appear that the author of either saw the other's work. It is often self-contradictory, and differs with the first book in the account of the death of Antiochus Epiphanes.

We are not aware when either Jason himself or his epitomiser lived. S. G. Hase supposes it to have been written B.C. 150, by the author of the *Book of Wisdom*. Jerome

(*Prolog. Galeat.*) observes that the phraseology of this Maccaroni. book evinces a Greek original. There have been two books of Maccabees found among the Chinese Jews; but whether they are the same with ours is doubtful.

The Third Book of Maccabees (the first in order of time) is still read in the Greek church, and is contained in the Alexandrian and Vatican MSS. (A. & B.). It contains an account of the persecution of the Egyptian Jews by Ptolemy Philopator, who is said to have proceeded to Jerusalem after his victory at Raphia over Antiochus the Great, B.C. 217, and after sacrificing in the temple, to have attempted to force his way into the Holy of Holies, when he was prostrated and rendered motionless by an invisible hand. Upon his return to Egypt, he revenged himself by shutting up the Jews in the Hippodrome, and exposing them to be crushed beneath the feet of elephants. This book contains an account of their deliverance by divine interposition. It is regarded by De Wette as a tasteless fable; and Dr Milman (*Hist. of the Jews*) describes it as a "romantic story." The author is unknown. Dr Allix (*Judgment of the Jewish Church*) considers it to have been written B.C. 200, and by the author of *Ecclesiasticus*. The work is first found in Latin in the edition of Frobenius (1538). It was translated into English by Walter Lynne (1550); by Whiston (*Authentic Documents*, 1719 and 1727); by Crutwell (*Bible*, 1785); and again by Dr Cotton (*Five Books of Maccabees*, 1832).

The Fourth Book of Maccabees, which is also found in the Alexandrian and Vatican MSS., is generally supposed to be the same with the *Supremacy of Reason*, attributed to Josephus, with which it for the most part accords. It consists of an inflated amplification of the history of the martyrdom of Eleazar and of the seven brothers, whose torments and death, with that of their mother, form the subject of 2 Macc., ch. vi. vii. It is found in the Greek Bibles printed at Basle in 1545, and at Francfort in 1597, where it is entitled *The Book of Josippos (Josephus) on the Maccabees*. It bears the same title in several other MSS. Calmet (*Pref. to the Fourth Book of Macc.*) has pointed out several contradictions between this and the second book, as well as the books of Moses, together with some opinions derived from the Stoics, such as the equality of crimes; which, he supposes, together with its tedious descriptions, have consigned it to the rank of an apocryphal book. The fourth book was printed by Dr Grabe from the Alexandrian MS. in the British Museum. There is a French translation by Calmet (*Commentary*), and an English one by Dr Cotton (*Five Books of Maccabees*, 1832).

What has been called the *Fifth Book of Maccabees* is now extant only in the Arabic and Syriac languages. It was first published, as the supposed *Fourth Book*, in the Paris Polyglott, with a Latin version, of which Dr Cotton has given a translation. It is impossible to ascertain the author, who could scarcely have been Josephus, as he disagrees in many things with that historian. The work consists of a history of Jewish affairs, commencing with the attempt on the treasury at Jerusalem by Heliodorus, and ending with the tragic fate of the last of the Asmonæan princes, and with the inhuman execution by Herod of his noble and virtuous wife Mariamne, and of his two sons. This history thus fills up the chasm to the birth of Christ.

The first two books of Maccabees have been treated with a high degree of respect in the Christian church. Origen, professing to give a catalogue of the canonical books, adds, "besides, there are the Maccabees." In his preface to the Psalms he excludes the two books of Maccabees from the books of holy Scripture. The first councils which included them in the canonical Scriptures were those of Hippo and Carthage, and they were not received with the other books till the Council of Trent.

Maccles-
field.

M'Crie.

long slender tubes, used in this country with cheese, and in soups, &c. It is a favourite dish with all classes in Naples, and a great many live on it almost exclusively. The flour, after being mixed with water, is kneaded by heavy wooden blocks, and then, when sufficiently tough, is forced through a number of holes so fashioned that it comes out in a tubular shape. The largest tubes are called *maccaroni*, the smaller *vermicelli*, and the smallest *fedelini*. After being properly boiled, it is taken out of the vessel, drained, saturated with gravy, and sprinkled with grated cheese. The poor, however, use it without condiment. The best *maccaroni* is to be found at Naples.

MACCLESFIELD, a municipal and parliamentary borough, and manufacturing town of England, county of Chester, on the Bollin, 17 miles S. by E. from Manchester, and 167 from London by railway. It is pleasantly situate on a declivity near the borders of Macclesfield Forest, and consists of four principal streets which meet in the market-place. The town is well supplied with water, brought from springs in the neighbouring hills; and baths and wash-houses have lately been established. The town-hall is a commodious and handsome Grecian building of recent erection, having, besides the courts of justice, offices, &c., a large assembly hall. The old church of St Michael, founded by Eleanor, queen of Edward I., in 1278, but since almost entirely rebuilt, is a large structure, partly Gothic, and has a massive tower, formerly surmounted by a lofty steeple. Several of the other churches are handsome buildings. The Independents, Methodists, Baptists, Roman Catholics, and others, have places of worship here. The free grammar school, founded in 1502 by Sir John Percival, and refounded by Edward VI., has a revenue of about £1500. A commercial school has recently been established on this foundation. There are also national, infant, charity, and other schools. A school of design was established here in 1851; and a subscription library, founded in 1770, now contains upwards of 20,000 volumes. The staple manufacture of Macclesfield is silk in all its various branches. About seventy mills are employed in throwing silk; besides which there are numerous establishments in which broad silks, handkerchiefs, and similar goods are made. The mills are mostly situate on the Bollin. The cotton manufacture has recently been introduced, and is now in a very flourishing condition. There are also several dye-works, foundries, and breweries in the town. Coal, slate, and stone are found in the vicinity. The Macclesfield Canal, which passes the town, unites the Grand Trunk and the Peak Forest canals, and thus affords water communication with most parts of England. Macclesfield was first incorporated by charter in 1260, by Prince Edward, son of Henry III. as Earl of Chester, but it had no voice in parliament till the Reform Bill granted it the privilege of returning two members. It is divided into six wards, and is governed by a mayor, 12 aldermen, and 36 councillors. Market-days, Tuesday and Saturday. Pop. (1851) 39,048.

M'CRIE, THOMAS, D.D., author of the *Life of Knox*, was born at Dunse, in North Britain, in the month of November 1772. His parents belonged to the class of Seceders known in Scotland as Antiburghers, and he was educated with a view to the ministry in that persuasion. After passing through the ordinary course of education afforded in a country town, he came to Edinburgh, and enrolled himself as a student in the university, in the winter of 1788. During that and the two following sessions he pursued the course of literary and philosophical study prescribed to students intending to devote themselves to the

ministry; and in 1791 he entered the theological class at Whitburn, under the Rev. Archibald Bruce, the teacher or professor of divinity to the Associate Antiburgher Synod. As the attendance upon this course was only for a limited period each year, it was usual for the students, whose means were generally very scanty, to employ the intervals in teaching. In this way Mr M'Crie, in the autumn of 1791, proceeded to Brechin, and opened a school in connection with the Associate Antiburgher congregation in that town; and he continued there, excepting the time annually required at Whitburn in the three following sessions (1792 to 1794) for completing the regular course of theological study.

In September 1795, Mr M'Crie was licensed to preach by the Associate presbytery of Kelso. In the beginning of the next year he received a call from the Second Associate Congregation of Antiburghers in Edinburgh; and some scruples having been obviated by an act of the Associate Synod, dated 3d May 1796, he was ordained to that charge on the 23d of that month. In this pastoral relationship he continued for upwards of ten years, evidently with the sincere attachment of his people.

At this period Mr M'Crie, by diligent and assiduous study, was acquiring that profound theological knowledge, and that fund of literary and ecclesiastical information, for which in after life he was so distinguished. The proceedings of the religious body with whom he was connected may also have had some effect in directing his pursuits towards subjects connected with the history, constitution, and polity of the Reformed church.

Mr M'Crie was one of five ministers who protested against what they considered to be a spirit of innovation on the part of the Synod, while engaged in the revision and enlargement of the *Judicial Act and Testimony*, which had hitherto served as the bond of ministerial and religious communion, in order, as it was expressed, to adapt it "more to the circumstances of the present time." The result of their proceedings was a sentence of deposition by the Associate Synod; and, in the case of Mr M'Crie, a litigation in the Court of Session. The task devolved upon Mr M'Crie to publish an explanation of the controversy between the Synod and them; and this appeared in 1807. Although of a controversial nature, respecting differences which attracted no very great share of public notice at the time, this Statement involves the discussion of principles which have since been much more widely agitated by the Voluntary question; and it has been appealed to by the friends of the Established Church, as explaining and enforcing the true grounds of connexion between the church and state, and as an able and elaborate argument of the obligation on civil rulers to make suitable provision for the religious interests of the community.

In the comparatively obscure and humble situation in which Mr M'Crie was now placed, he was enabled to devote his leisure hours to his favourite literary pursuits. *The Life of John Knox, containing Illustrations of the History of the Reformation in Scotland*, appeared in the beginning of 1812, in 1 vol. 8vo, pp. 580, and a new edition appeared in an enlarged and corrected form in 1813.¹

The next subject in which Dr M'Crie engaged was a *Life of Andrew Melville*, the able and intrepid assertor of Presbytery; which might serve as a continuation to his former work, by giving an account of ecclesiastical transactions in Scotland during the latter part of the sixteenth and beginning of the seventeenth century. This work was published in 1819, in 2 vols. 8vo.²

In 1817 Dr M'Crie took occasion, in a review of the

¹ The fifth edition, carefully revised by the author, and containing his last corrections, was published in 1831, 2 vols. 8vo.

² The title is, *The Life of Andrew Melville; containing Illustrations of the Ecclesiastical and Literary History of Scotland during the latter part of the Sixteenth and beginning of the Seventeenth Century. With an Appendix consisting of original papers.* A second edition, revised, was published in 1824, also in 2 vols. 8vo.

M'Crie.

M'Crie. first series of the *Tales of my Landlord*, to offer an elaborate defence of the Covenanters. Sir Walter Scott, who had not then stood forth as the acknowledged author of the *Waverley Novels*, was persuaded by the editor of the *Quarterly Review* to become the reviewer of his own work, when he took the opportunity of vindicating his statements in answer to the article in the magazine.

In February 1816, Dr M'Crie succeeded the Reverend Archibald Bruce, Antiburgher minister at Whitburn, as professor of divinity. On the union of the two seceding bodies, under the designation of the "Associate Synod of Original Seceders," Dr M'Crie resigned the divinity chair to the Rev. Dr Paxton, author of *Illustrations of the Holy Scriptures*; and resuming his literary labours, he next published, in 1821, *Two Discourses on the Unity of the Church*. This was followed in 1825 by a volume entitled *Memoirs of Mr William Veitch and George Bryson, written by themselves: with other Narratives Illustrative of the History of Scotland, from the Restoration to the Revolution: to which are added, Biographical Sketches and Notes*, 8vo, pp. 540.

The next subject of his investigation led to the publication, in 1827, of a *History of the Progress and Suppression of the Reformation in Italy in the Sixteenth Century, including a Sketch of the Reformation in the Grisons*, 8vo, pp. 484. Also, in 1829, as a sequel to that work, a *History of the Progress and Suppression of the Reformation in Spain in the Sixteenth Century*. 8vo, pp. 424. These volumes undoubtedly form a valuable accession to the history of the Reformation throughout Europe, although the author laboured under great disadvantages in having but limited access to original sources of information, compared to what was within his reach in matters of our own ecclesiastical history. Both volumes, however, present masterly sketches of the periods of which they treat, and no subsequent historian has arisen to give a more extended history of the suppressed reformations on the continent.

Dr M'Crie was induced to undertake a life of John Calvin the Reformer, which had been looked for from his hand, and which he himself had long contemplated; and he had made some progress in writing the introductory portion at the time when his earthly labours were brought to a close in the summer of 1835.¹ He was interred in the New Greyfriars burying-ground.

A detailed and interesting *Life* by his eldest son, the Rev. Dr M'Crie, appeared in 1840. To his care we are also indebted for the publication of a posthumous volume of *Sermons*, 1836; a collection of his *Miscellaneous Writings*, 1841; sketches of *Lectures on Esther*; and a complete edition of his works in crown 8vo.

In private life, Dr M'Crie was dignified, kind, affable, and free from everything like display or desire of notoriety; being remarkable for his cordiality of manners, cheerfulness of temper and conversation, and his unaffected simplicity. As a preacher, his style of address was rather unprepossessing, partly from want of action, and partly from his slow, monotonous, and somewhat constrained delivery, as if afraid to speak out in the natural tone of his voice. But any deficiency of artificial eloquence was amply compensated for by his profound and luminous expositions of Scripture, expressed in clear and energetic language; and several of his printed discourses make good his claim to stand in the first rank of Scottish preachers. In his literary character, by which he will be known in after times, it will be acknowledged that his mind was of no ordinary cast. With extensive erudition, and habits of indefatigable research, he combined sound judgment, and a singular acuteness and sagacity of intellect. His learning

was both profound and extensive, as he was not only skilled in what are called the learned languages, but was conversant with most of those of modern Europe. Still, with all his natural love of literary pursuits, he kept such employment in subservience to his duty as a diligent and faithful minister of Christ. For nearly forty years he laboured with the most affectionate solicitude for the spiritual interests of his flock, and much of his time was devoted to them in his week-day ministrations. It was chiefly a consideration of the paramount importance of such a charge, we imagine, that caused him to decline the prospect of a chair in the University of Edinburgh. There is every reason also to believe, that had his life been spared a few months longer, the honorary office of Historiographer-Royal for Scotland would have been conferred, unsolicited, upon him, as a public testimony due to him. He has been styled by Hallam the "Hildebrand of the Reformation;" but it must be confessed that his warm championship of Knox was the result of profound conviction and untiring research. The philosophic wisdom and candour that pervade his writings are rarely to be found in the productions of men subjected, as he was early and for a long period, to neglect and poverty for conscience sake.

MACCULLOCH, DR JOHN, a miscellaneous writer, descended from an old Scottish family, was born at Guernsey in 1773. While still a child, he removed with his family to Cornwall, and after attending several schools, was at last sent in 1787 to the grammar school of Lostwithiel. In 1790 he began the study of medicine at Edinburgh; and at the early age of eighteen received the diploma of physician. Too young, however, for private practice, he remained in Edinburgh for five years, and after filling successively the offices of assistant-surgeon in the artillery, and chemist to the Board of Ordnance, he settled in 1807 as a physician at Blackheath. This profession he relinquished in 1811, and for several years afterwards he was employed by government in making various surveys in Scotland. Of these, the most important was his mineralogical and geological survey of that country, begun in 1826 and completed in 1832. He died at Penzance in 1835, from the effects of a fall. At the period of his death Dr Macculloch was lecturer on geology and chemistry in the military establishment at Addiscombe. He had also been appointed, in 1820, physician in ordinary to Leopold of Saxe-Coburg, and was fellow of the Royal, Linnean, and Geological Societies. In addition to the knowledge of mathematics, geology, mineralogy, medicine, chemistry, and theology, displayed in his various works, he possessed an acquaintance with physics, botany, zoology, astronomy, and the mechanical arts. He was also skilled in music, drawing, and architecture. He published *Remarks on the Art of Making Wine*, 12mo, 1816; *A Description of the Western Islands of Scotland*, in 2 vols. 8vo, London, 1819; *A Geological Classification of Rocks*, 8vo, London, 1821; and *The Highlands and Western Islands of Scotland, containing Descriptions of the Scenery, Antiquities, &c.*, in 4 vols. 8vo, London, 1824. In 1837 was published his posthumous work, entitled *Proofs and Illustrations of the Attributes of God from the Facts and Laws of the Physical Universe, being the Foundation of Natural and Revealed Religion*, in 3 vols. 8vo, London. He also contributed several papers to the seventh edition of this Encyclopædia, to the *Transactions of the Geological Society*, to the *Edinburgh Review*, and to other periodicals.

MACDIARMID, JOHN, was born at Edinburgh in 1789, and educated at the university of that city, where he afterwards commenced his career as a clerk in the Commercial Bank. Having a taste for literature, which he as-

diarmid.

¹ It may be noticed, that Dr M'Crie, in May 1834, visited London to give his evidence before the Committee of the House of Commons on Church Patronage. His evidence forms part of the voluminous Report on that question, pp. 356-374, and 383-393.

Macdonald
||
Macedo.

siduously cultivated, he became editor of the *Dumfries Courier* in 1817, which he conducted with originality and taste. He died November 12, 1852. In addition to his contributions to the newspaper, he published *The History of Dumfries, A Guide to Moffat, A Life of Cowper, A Life of William Nicholson the Galloway Poet, Sketches from Nature, The Scrap-Book, &c.*

MACDONALD, ETIENNE-JACQUES-JOSEPH-ALEXANDRE, *Duke of Tarentum*, was descended from a Scottish family, and was born in 1765 at Sancerre, in France. He entered the French army in 1784, and having embraced the principles of the Revolution, served in the army of the north as brigadier-general; but in 1795 was promoted for his bravery to the rank of general of division. In this capacity he commanded at Düsseldorf and Cologne. After serving in the army of the Rhine, he acted under Bonaparte in the army of Italy, and in 1798 became governor of the Roman States. Forced, however, in 1799 to retreat before Suwaroff and Melas, he was defeated by them at Trebia, and with great difficulty effected a conjunction with Moreau at Genoa. In the revolution of the 18th Brumaire, Macdonald ably seconded Bonaparte; and in 1800 was rewarded for his services with the command of an army of reserve in Switzerland. There he displayed great military skill in his passage of the Splügen. On his return to Paris in 1802, he was appointed French plenipotentiary at the court of Denmark, and at the expiry of this office, he was decorated with the star of a Grand Officer of the Legion of Honour. For his bold defence of Moreau, Macdonald forfeited the favour of Bonaparte. Yet in 1809, so brilliant was his success in defeating the enemy's centre at Wagram, that Napoleon acknowledged his bravery in presence of the army, and bestowed upon him the marshal's staff and the title of Duke of Tarentum. No less noted was his military prowess in the famous invasion of Russia, and in the battles of Lutzen, Bautzen, and Leipsic. During the Hundred Days, Macdonald lived in retirement. After the downfall of Napoleon he was appointed chancellor of the Legion of Honour, an office which he held till 1831. In 1825 he attended Charles X. to the coronation at Rheims, and afterwards visited Great Britain and Ireland. He died in 1840.

MACDUFF, a burgh of barony and seaport-town of Scotland, county of Banff, on the right bank of the Deveron, at its mouth, and connected with the town of Banff on the opposite bank by a stone bridge of seven arches. It has a town-hall, jail, an Established and a Free church, and an excellent harbour, by means of which a considerable coasting trade is carried on. It is included in the parliamentary burgh of Banff. Pop. (1851) 2527.

MACE, the external covering or arillode of the seed of the nutmeg, of a scarlet colour, and fatty, shining appearance. (See *Myristica moschata*, in BOTANY.) It is strongly aromatic and of a pungent acid taste. It is packed in bales, and imported from the Moluccas, where the best is to be found. The import trade in mace for home consumption for the three years ending with 31st December 1856, has been as follows:—in 1854, 25,584 lb.; in 1855, 28,563 lb.; in 1856, 27,299 lb. The present (1857) duty on mace is 1s. per lb.

MACEDO, JOSE AGOSTINHO DE, a Portuguese poet, was born about 1770. He studied for the church, became an Augustine monk, and in 1810 was chaplain to the Prince Regent of Portugal, and one of the most popular preachers in Lisbon. In 1811 he published *Reflections on the Episode of Adamastor in the Lusiad*, in which he convicted Camoens of plagiarism from the Italian poets. He also wrote an epic poem, *O Oriente* (The Orient), in celebration of the discovery of India; a didactic poem, entitled *A Meditação* (Meditation); a translation of Horace; and several controversial pamphlets. Macedo died in 1831.

MACEDONIA, or MACEDON, a celebrated kingdom of Macedonia antiquity, was bounded on the E. by the Ægean Sea, on the S. by Thessaly and Æpirus, on the W. by the Ionian Sea or Adriatic, on the N. at first by the river Strymon and the Scardian Mountains, but afterwards by the River Nessus or Nestus. In a direct line the whole country extended only 150 miles; but it was lengthened out to about three times that extent by the windings of the coast, in which almost every convenient situation was converted into a Grecian seaport. The country was naturally divided by the Thernaic and Strymonic gulfs, into the provinces of Pieria, Chalcis, and Pangæus. The middle region, which took its name from a city of Eubœa, whence it had been originally peopled, was very fertile and pleasant; and the interior, being diversified by lakes, rivers, and arms of the sea, was extremely convenient for inland navigation, whilst the towns of Amphipolis, Potidæa, Acanthus, and many others, afforded marts for the commerce of the republics of Greece, as well as of Thrace and Macedonia. On one side of this district were the mountains of Pangæus, and on the other the plains of Pieria. The Pangæan Mountains, which extended 90 miles towards the E. and the River Nessus, though proper neither for corn nor pasture, produced plenty of timber for ship-building; whilst the southern branches of the mountains contained rich veins of gold and silver. Pieria extended 50 miles along the Thernaic Gulf, as far as the confines of Thessaly and Mount Pindus.

In the most ancient times this country was called *Æm-* Different
thia, from Æmathius, one of its princes. The name of names.
Macedonia is said to have been derived from Macedo, a descendant of Deucalion; though others suppose it to have been only a corruption of *Mygdonia*, a district of the country. In those remote ages of antiquity, Macedonia, like most other countries of Europe, was divided into a great number of petty principalities, of which scarcely even the names are now known.

That section of the race which went under the name of *Macedonian*, and which afterwards swallowed up all the rest and became known as the *Macedonians*, had their origin at Ægæ or Edessa, corresponding with the site of the modern Vodhena. And though, in after times, the royal residence was removed to Pella, yet the original centre was always retained as the burial-place of their kings, and the hearth around which the national reverence and affection clung.

The origin of the Macedonian people and that of the Macedonian monarchy are quite distinct. The former have been regarded as of Illyrian, the latter of Hellenic race. We learn from Polybius, the best authority which we possess (xxviii., 8, 9), that the Macedonian language was different from the Illyrian,—a circumstance which, in the opinion of Mr Grote (*History of Greece*, vol. iv., p. 14), is sufficient to cast serious doubt on the supposed Illyrian descent of those races.

All the stories relative to the early history of the Macedonian monarchy—and they were various—agree in tracing the origin of the family to the Temenids of Argos. There is an air of genuineness about the tradition of Herodotus (viii., 137–138). According to this historian, Perdicas, a Temenid, with two brothers of the same race, being driven from their native Argos into Macedonia, were compelled, from straitened circumstances, to serve as shepherds to the petty King of Labæa. A prodigy happened to Perdicas, which at once indicated his future success, and led to his present dismissal by the Labæan. His escape being secured by the rising of a river, which was afterwards held sacred by the Macedonian kings, this hardy shepherd established himself near the garden of Midas, on Mount Bermius, and from him sprang the royal line of Edessa. It was a common Greek opinion, moreover, during the reign of Alexander, son of Amyntas, that the family of that prince was of Hellenic extraction; so much so, that he found a place

Macedonia. at the Olympic games, to which none but a genuine Greek could lay claim.

To command was the prerogative of the Greek mind, and for a courageous Argeian to acquire ascendancy and transmit authority over the Macedonian barbarians was doubtless a task of comparatively little difficulty. From the legend alluded to till the reign of Amyntas (520-500 B.C.) and his son Alexander (480 B.C.), we have nothing but a long blank. Names or dates there are none; yet, we can dimly infer the growing influence and importance of the Temenids. They acquire Pieria, a place of great importance, lying between Mount Bermius and the sea. Amyntas accordingly heired an extensive dominion on his coming to the throne. During his reign he kept up a friendly connexion with the Pisistratidæ at Athens, a relationship afterwards continued between his son Alexander and the Athenians. It was during the reign of Amyntas that Macedonia first became formally subject to the Persian power. Darius intrusted his officer Megabazus with the important task of ratifying the submission which Amyntas had proposed, and the Persian warrior and diplomatist fulfilled his mission so well, that after marrying the sister of Amyntas, he returned to his master with a new province added to his empire.

The Macedonians distinguished themselves in the time of the Persian invasion of Greece by furnishing their allies with 200,000 recruits; though some cities, particularly Potidæa, Olynthus, and Pallene, adhered to the Grecian interest. The last two were taken and razed, and the inhabitants massacred by the Persians; but Potidæa escaped by reason of the sea breaking into the Persian camp, where it did great damage. Alexander, however, afterwards thought proper to court the favour of the Greeks, by giving them intelligence of the time when Mardonius designed to attack them. The remaining transactions of this reign are entirely unknown, further than that the king enlarged his dominions as far as the river Nessus on the E., and the Axius on the W.

Reign of
Perdiccas
II.

Alexander I. was succeeded by his son Perdiccas II., who is said to have inherited his father's abilities, though not his integrity. From the duplicity with which he acted, both to the Greeks and the Persians, it does not appear, indeed, that he had much to boast of as to the latter quality. In the Peloponnesian war he espoused the cause of the Spartans against the Athenians, from whom he was in danger by reason of their numerous settlements on the Macedonian coast, and their great power by sea. For some time, however, he amused the Athenians with a show of friendship; but at last, under pretence of enabling Olynthus and some other cities to recover their liberties, he assisted in destroying the influence of the Athenians in those places, hoping to establish that of the Macedonians in its stead. But this design failed of success; the Olynthian confederacy was broken up; and the members of it became subject to Sparta, until at last, by the misfortune of that republic, they grew sufficiently powerful, not only to resist the encroachments of the Macedonians, but to make considerable conquests in their country.

Archelaus
I.

Perdiccas II. was succeeded about 416 B.C. by Archelaus I. He enlarged his dominions by the conquest of Pydna and other places in Pieria, though his ambition seems rather to have been to improve his dominions than greatly to extend them. He facilitated communication between the principal towns of Macedonia, by cutting straight roads through the greater part of the country; he built walls and fortresses in such places as afforded favourable situations; he encouraged agriculture and the arts, particularly those subservient to war; he formed magazines of arms; he raised and disciplined a considerable body of cavalry; and, in a word, he added more to the solid grandeur of Macedonia than had been done by all his predecessors

put together (*Thuc.*, ii. 100). Nor was he regardless of Macedonia. the arts of peace. His palace was adorned by the works of the Grecian painters. Euripides was long entertained at his court; Socrates was earnestly solicited to live there; men of merit and genius in the various walks of literature and science were invited to reside in Macedonia, and treated with distinguished regard by a monarch equally attentive to advance his own glory and promote the happiness of his subjects.

This great monarch died after a reign of six years, a space by far too short to accomplish the magnificent projects he had formed. After his death the kingdom fell under the power of usurpers, or of weak and wicked monarchs. A number of competitors constantly appeared for the throne; and these by turns called to their assistance the Thracians, Illyrians, Thessalians, the Olynthian confederacy, Athens, Sparta, and Thebes. Bardyllis, an active and daring chief, who, from being the head of a gang of robbers, had become sovereign of the Illyrians, entered Macedonia at the head of a numerous army; deposed Amyntas II., father of Philip; and set up in his stead one Argæus, who consented to become tributary to the Illyrians. Another candidate for the throne, named Pausanias, was supported by the Thracians; but, by the assistance of the Thessalians and Olynthians, Amyntas was at length enabled to resume the government. After his restoration, however, the Olynthians refused to deliver up several places of importance belonging to Macedonia, which Amyntas had either intrusted to their care, or which they had taken from his antagonist. Amyntas complained to Sparta, and that republic readily complied with his wishes. Two thousand Spartans, under the command of Eudamidas, were ordered into Macedonia, where they performed essential service. The appearance of a Spartan army at once encouraged the subjects and allies of the Olynthians to revolt; and the city of Potidæa, a place of great importance in the isthmus of Pallene, surrendered soon after his arrival in the country. Elated with his success, Eudamidas approached so near the city of Olynthus, that he was unexpectedly attacked, defeated, and killed, in a sally of the citizens. He was succeeded by Teleutias, brother of Agesilaus, who had under his command a body of ten thousand men, and was further assisted by Amyntas, king of Macedonia, and Derdas his brother, the governor or sovereign of the most westerly province of Macedonia, which abounded in cavalry. By these formidable enemies the Olynthians were discomfited in a series of battles, obliged to shut themselves up in their city, and prevented from cultivating their territory; upon which Teleutias advanced with his whole forces to invest the city itself. The Olynthians allowed them to come on, and the Lacedæmonians imprudently advanced under the towers and battlements of the city. The townsmen then mounted the walls, and discharged upon them a shower of darts, arrows, and other missile weapons, whilst the flower of the Olynthian troops, who had been purposely posted behind the gates, sallied forth and attacked them with the greatest fury. Teleutias, attempting to rally his men, was slain in the first onset; the Spartans who attended him were defeated, and the whole army dispersed with great slaughter, and obliged to shelter themselves in the towns of Acanthus, Apollonia, Spartolus, and Potidæa.

The Spartans, undismayed by this disaster, prosecuted the war with much spirit. The Olynthians held out for nine or ten months, but were at last obliged to submit on very humiliating conditions. They formally renounced all claim to the dominion of Chalcis, and ceded the Macedonian cities to their ancient governor; and in consequence of this, Amyntas left the city of Ægæ, or Edessa, where till now he had held his royal residence, and fixed it at Pella, a city of great strength and beauty, situate upon an eminence, which, together with a plain of considerable extent, was defended

Civil dis-
sensations.

Submission
of the Olyn-
thians.

Macedonia. by impassable morasses, and also by the rivers Axios and Lydias. It was distant about 15 miles from the Ægean Sea, with which it communicated by means of the above-mentioned rivers. It was originally founded by the Greeks who had conquered and peopled it; but, in consequence of the misfortunes of Olynthus, it now became, and continued ever after to be, the capital of Macedonia.

Pausanias; Amyntas being thus established in his dominions, continued to enjoy tranquillity during the remaining part of his life. The reign of his son Alexander was short, and disturbed by invasions of the Illyrians, from whom he was obliged to purchase a peace. He left behind him two brothers, Perdiccas and Philip, both very young, so that Pausanias again found means to usurp the throne, being supported not only by the Thracians, but by a considerable number of Greek mercenaries, as well as a powerful party in Macedonia itself. In this critical juncture, however, Iphicrates the Athenian happening to be on an expedition to Amphipolis, was so warmly addressed by Eurydice, the widow of Amyntas, in behalf of her two sons, whom she presented to him, that he interested himself in their behalf, and got Perdiccas, the eldest, established on the throne. During the minority of the young prince, however, his brother Ptolemy, who was his guardian, openly aspired to the throne; but he was deposed by the Theban general Pelopidas, who reinstated Perdiccas in his dominions, and in order to secure the dependence of Macedonia upon Thebes, carried along with him thirty Macedonian youths as hostages, amongst whom was Philip, the younger brother of the king. Perdiccas, elated by the protection of such powerful allies, now forgot Iphicrates and the Athenians, and even disputed with them the right to the city of Amphipolis, which had been decreed to them by the general council of Greece, but which his opposition rendered it impossible for them to recover. In a battle with the Illyrians, the Macedonians were defeated with the loss of 4000 men, and Perdiccas himself was taken prisoner, and soon afterwards died of his wounds.

State of the kingdom. The kingdom was now left in the most deplorable state. Amyntas, the legitimate heir to the throne, was an infant; the Thebans, in whom Perdiccas had placed so much confidence, were deprived of the sovereignty of Greece; the Athenians, justly provoked at the ungrateful behaviour of the late monarch, showed a hostile disposition; the Illyrians ravaged the western, and the Pæonians the northern quarter of the kingdom; the Thracians still supported the cause of Pausanias, and proposed to send him into Macedonia at the head of a numerous army; whilst Argæus, the former rival of Amyntas, renewed his pretensions to the throne, and by flattering the Athenians with the hopes of recovering Amphipolis, easily induced them to support his claims, in consequence of which they fitted out a fleet, having on board 3000 heavily armed soldiers, which they sent to the coast of Macedonia.

Arrival of Philip in Macedonia. Philip, the late king's brother, no sooner heard of his defeat and death, than he set out privately from Thebes, and on his arrival in Macedonia found matters in the situation which we have just described. Fired with an insatiable ambition, it is probable that from the very first moment he had resolved to seize the kingdom for himself; yet it was necessary at first to pretend that he assumed the throne only to preserve it for his nephew. Philip, as has already been mentioned, had been carried off as a hostage by Pelopidas, but for a long time past had remained in such obscurity that historians are not agreed as to his place of residence, some placing him in Thebes, and others in Macedonia. It is certain, however, that from the age of fifteen he had been very much in the family of Epaminondas, from whose lessons he could not but derive the greatest advantage. It is also probable that he accompanied this celebrated general in many of his expeditions; and it is certain that, with an attendance suitable to his rank, he visited most of

the principal republics, and paid great attention to their institutions, both civil and military. Having easy access to whomsoever he pleased, he cultivated the friendship of the first people in Greece. Even in Athens, where no good will subsisted to Macedonia, the philosophers Plato, Isocrates, and Aristotle, cultivated his acquaintance; and the connection he formed with the principal leaders of that republic in the early period of his life no doubt contributed greatly to the accomplishment of the designs in which he afterwards proved so successful.

Philip's return to Macedonia instantly changed the face of affairs. The Macedonian army, though defeated, was not entirely destroyed; and the remainder of them secured themselves in the fortresses which had been built by Archelaus. There were also considerable garrisons in the fortresses and walled towns scattered over the kingdom; and the Illyrians, who had made war only for the sake of plunder, soon returned home to enjoy the fruits of their victory. His other enemies, the Thracians and Pæonians, were much less formidable than the Illyrians, being still in a very rude and uncivilized state, incapable of uniting under one head in such a manner as to bring any formidable army into the field. Whilst the Illyrians therefore gave up the campaign through mere caprice and unsteadiness, Philip himself applied to the Pæonians, and by fair promises and flattery, prevailed upon them to desist. The King of Thrace, by means of a sum of money, was easily induced to abandon the cause of Pausanias; so that Philip, freed from these barbarians, was now at liberty to oppose the Athenians, who supported Argæus, and threatened a very formidable invasion.

The appearance of the Athenian fleet before Methone, and the presence of Argæus at the head of a numerous army in Pieria, filled the whole country with consternation; and Philip, who was by no means deficient in the talents necessary to recommend himself to the good graces of the people, took the opportunity of getting Amyntas set aside and himself declared king, for which proceeding indeed the danger of the times afforded a very plausible pretext. In the meantime, Argæus advanced with his Athenian allies towards Edessa, or Ægæ, but was defeated by Philip in a general engagement, in which Argæus himself, with the flower of his army, was cut in pieces, and the rest taken prisoners. This first instance of success contributed greatly to raise the spirits of Philip's party; and he himself took care to improve it in the best manner possible. Having made a great number of prisoners, both Macedonians and Athenians, he determined, by his treatment of them, to ingratiate himself with both parties. The former were called into his presence, and, after a gentle reprimand, admitted to swear allegiance to him, after which they were distributed throughout the army. The Athenians were entertained at his table, and dismissed without ransom, and their baggage was restored to them. The prisoners were just allowed time to return to their native city, and to spread abroad the news of Philip's generosity, when they were followed by ambassadors from Macedonia with proposals for peace. As he knew that the loss of Amphipolis had greatly irritated them, he now thought proper to renounce his jurisdiction over that city. It was accordingly declared free and independent, and subject only to the government of its own free and equitable laws. This prudent conduct, together with his kind treatment of the prisoners, so wrought upon the minds of the Athenians, that they consented to the renewal of a treaty which had formerly subsisted between them and his father Amyntas. Thus he found means to remove all jealousy of his ambition, and to induce them to engage in a ruinous war with their allies, which occupied their attention until Philip had an opportunity of getting matters so well established that it was impossible to overthrow him.

Affairs of the kingdom retrieved by him.

Philip assumes the sovereignty.

Macedonia. The new king being thus at liberty to regulate his domestic concerns, began to circumscribe the power of his chiefs and nobles, who, especially in the more remote provinces, paid very little regard to the authority of the kings of Macedonia. To counteract the ambition of these chiefs, Philip chose a body of the bravest Macedonian youths, whom he entertained at his own table, and honoured with many testimonies of his friendship, giving them the title of his "companions," and allowing them constantly to attend him in war and hunting. Their intimacy with the sovereign, which was considered as a sure indication of their merit, obliged them to use superior diligence in all the severe duties of military discipline; so that they thus formed a useful seminary for future generals, by whom both Philip and Alexander were afterwards greatly assisted in their conquests.

The Pæonians and Illyrians. Whilst the king thus took the best methods to render himself secure at home and formidable abroad, the Pæonians again began to make incursions into the kingdom. The death of Agis, their king, however, who was a man of great military skill, deprived them of almost all power of resistance when they were attacked. Philip, in consequence, overran their country with little opposition, and reduced them to the state of tributaries to Macedonia. No sooner was this accomplished, than he undertook a winter's campaign against the Illyrians, who had long been the natural enemies of Macedonia. After an ineffectual negotiation, he was met by their leader Bardyllis at the head of a considerable body of infantry, but with only 400 horse. They made a gallant resistance for some time; but being unable to contend with so skilful a general as Philip, they were defeated with the loss of 7000 men, amongst whom was Bardyllis, who fell at the age of ninety.

By this disaster the Illyrians were so much disheartened, that they sent ambassadors to Philip, humbly begging for peace upon any terms. The conqueror granted them the same conditions which had been imposed upon the Pæonians, viz., becoming tributary, and yielding up to him a considerable part of their country. This territory, hitherto unconnected with any foreign power, gradually sunk into such absolute dependence upon Macedonia, that many ancient geographers supposed it to be a province of that country.

Designs and proceedings of Philip.
B.C. 357. Philip had no sooner reduced the Illyrians, than he began to put in execution greater designs than any which he had yet attempted. Sensible of the importance of Amphipolis as a maritime station, he directed all his efforts towards the reduction of that city. It had indeed been declared independent by Philip himself in the beginning of his reign; but this was only to prevent a rupture with the Athenians, who still asserted their right to it as an ancient colony, though, by reason of the perfidy of Charidemus, a native of Eubœa, they had hitherto failed in their attempts to recover it. The Amphipolitans, however, having once enjoyed the sweets of liberty, prepared to maintain themselves in their independence. In the meantime, the hostile designs of Philip, which all his precaution had not been able to conceal, alarmed the inhabitants to such a degree that they thought proper to put themselves under the protection of the Olynthians. By them they were readily received into the confederacy, and, trusting to the strength of their new allies, behaved in such an insolent manner to Philip, that he was not long in finding a specious pretext for hostility; on which the Olynthians, greatly alarmed, sent ambassadors to Athens, requesting their assistance against such a powerful enemy. Philip, however, justly alarmed at such a formidable conspiracy, sent agents to Athens with such expedition that they arrived there before anything could be concluded with the Olynthian deputies. Having gained over the popular leaders and orators, he deceived and flattered the magistrates and senate in such an artful manner, that a negotiation was instantly set on

foot, by which Philip engaged to conquer Amphipolis for Macedonia. the Athenians, upon condition that they surrendered to him the strong fortress of Pydna, a place which he represented as of much less importance to them; promising also to confer upon them many other advantages, which, however, he did not specify at that time. Thus the Athenians, deceived by the perfidy of their own magistrates, elated with the hopes of recovering Amphipolis, and outwitted by the superior policy of Philip, rejected with disdain the proffers of the Olynthians.

The ambassadors of Olynthus returned home highly disgusted with the reception they had met with, but had scarcely time to communicate their news to their countrymen, when the ambassadors of Philip arrived at Olynthus. He pretended to condole with them on the affront they had received at Athens, but also testified his surprise that they should court the assistance of that distant and haughty republic, when they could avail themselves of the powerful kingdom of Macedonia, which wished for nothing more than to enter into equal and lasting engagements with their confederacy. As a proof of his moderation and sincerity, he offered to put them in possession of Anthemus, an important town in the neighbourhood, of which the Macedonians had long claimed the jurisdiction; making many other fair promises, and, amongst the rest, that he would reduce for them the cities of Pydna and Potidæa, which he chose rather to see in dependence on Olynthus than Athens. Thus he prevailed upon the Olynthians not only to abandon Amphipolis, but to assist him with all their power in the execution of his designs.

Philip now lost no time in executing his purposes against Amphipolis, and pressed the city so closely that the people were glad to apply to the Athenians for relief. Accordingly, they despatched two of their most eminent citizens, Hierax and Stratocles, to represent the danger of an alliance between Philip and the Olynthians, and to profess their sorrow for having so deeply offended the parent state. This representation had such an effect, that though the Athenians were then deeply engaged in the Social War, they would probably have paid some attention to the Amphipolitans, had not Philip taken care to send them a letter with fresh assurances of friendship, acknowledging their right to Amphipolis, and which he hoped shortly to put into their hands in terms of his recent agreement. By these specious pretences the Athenians were persuaded to pay as little regard to the deputies of the Amphipolitans as they had already done to those of the Olynthians; so that the city, unable to defend itself alone against so powerful an enemy, at last surrendered at discretion in the year 357 before Christ.

Finding that it was not his interest at this time to fall out with the Olynthians, Philip cultivated the friendship of that republic with great assiduity; and took the cities of Pydna and Potidæa, which he readily yielded to the Olynthians, though they had given him but little assistance in the reduction of these places. Potidæa had been garrisoned by the Athenians, and them the artful king sent back without ransom, lamenting the necessity of his affairs, which obliged him, contrary to his inclination, to oppose their republic. Though this was rather too gross, the Athenians were then so much engaged with the Social War, that they had not leisure to attend to the affairs of other nations. Philip made the best use of his time, and next projected the conquest of the gold mines of Thrace. These had formerly been worked by colonies from Thasos and Athens; but the colonists had long since been expelled by the barbarous Thracians, who knew not how to make use of the treasure they were in possession of. Philip took the trouble to descend into the mines himself, in order to inspect the works; and, having caused them to be repaired, planted a Macedonian colony at Crenidæ, bestowed upon it the name

Macedonia. of Philippi, and drew annually from the gold mines to the value of nearly 1000 talents, or L.200,000 sterling, an immense sum in those days. The coins struck here were likewise called Philippi.

The affairs of Thessaly settled. Philip having obtained this valuable acquisition, next undertook to settle the affairs of Thessaly, where everything was in the greatest confusion. This country had been formerly oppressed by Alexander, tyrant of Pheræ, after whose death three others appeared, viz., Tissiphornus, Pitholaus, and Lycophron, the brothers-in-law of Alexander, who had likewise murdered him. By the united efforts of the Thessalians and Macedonians, however, these usurpers were easily overthrown, and effectually prevented from making any disturbances for the future; and the Thessalians, from a mistaken gratitude, surrendered to Philip all the revenues arising from their fairs and towns of commerce, as well as all the conveniences of their harbours and shipping; a concession which Philip took care to secure in the most effectual manner.

Combination against Philip. B.C. 356. Having now not only established his sovereignty in the most effectual manner, but rendered himself very powerful and formidable to his neighbours, Philip determined to enjoy some repose from his fatigues. Having formed an alliance with Arybbas, King of Epirus, he, in the year 357 B.C., married Olympias, the sister of that prince; a match thought the more eligible, as the kings of Epirus were supposed to be descended from Achilles. The nuptials were solemnized with great pomp at Pella, and several months were spent in shows and diversions, during which Philip showed such an extreme proneness to vice of every kind, as disgraced him in the eyes of his neighbours, and most probably laid the foundation of his future domestic unhappiness. So much was this behaviour of the Macedonian monarch taken notice of by the neighbouring states, that the Pæonians and Illyrians threw off the yoke, engaging in their schemes the King of Thrace; and, notwithstanding the insane state of that prince, their designs were now carried on with more judgment than was usual with barbarians. Philip, however, notwithstanding his dissipation, got warning of his danger in sufficient time to prevent the evil consequences which might have ensued had the confederates had time to bring their schemes to a proper bearing. Early in the spring of 356 he took the field with the flower of the Macedonian troops. Having marched in person against the Pæonians and Thracians, he despatched Parmenio, his best general, into Illyria. Both enterprises proved successful; and whilst Philip returned victorious from Thrace, he received an account of the victory gained by Parmenio; a second messenger informed him of a victory gained by his chariot at the Olympic games; and a third announced that Olympias had been delivered of a son at Pella.

Alexander the Great. B.C. 356. This was the celebrated Alexander, to whom the diviners prophesied the highest prosperity and glory, as being born in such auspicious circumstances. A short time after the birth of Alexander, Philip wrote a letter to the philosopher Aristotle, whom he chose as preceptor to his son. The letter was written with great brevity, containing only the following words:—"Know that a son is born to us. We thank the gods not so much for their gift, as for bestowing it at a time when Aristotle lives. We assure ourselves that you will form him a prince worthy of his father, and worthy of Macedonia."

Phocian war. B.C. 357-346. Philip next set about the further enlargement of his territories, which were already very considerable. He easily perceived that the affairs of the Greeks were coming to a crisis, and he determined to watch the issue of their mutual dissensions. He found occasion of interference for the first time with the affairs of Greece, at the outbreak of the *Phocian* or Sacred War. The true cause of the persecution of the Phocians, it is believed, was the hatred with which that

people had inspired the Thebans by refusing them aid in Macedonia, their recent contest with Sparta. Private individuals also of the neighbouring communities advanced doubtful motives of personal offence. Such were the passions which moved the Thebans to a course of rash and cruel warfare, which eventually wrought their own ruin, and led to the destruction of Grecian freedom. Prompted by ambition and avarice, they aspired to absolute control in the Amphictyonic Council, and to undivided authority over the temple of Delphi and its treasures, then in the rightful possession of the Phocians. A quarrel was sought with this unoffending people. They were charged by their rapacious neighbours with having cultivated lands which had been devoted to the god of Delphi. Ascendant in the council, the Thebans easily found means of criminating the Phocians; they accordingly condemned that much-wronged people to pay a fine, for the liquidation of which their entire country was pronounced forfeit to the god. The Phocians boldly seized upon Delphi, and appealed to arms (B.C. 357); and under the encouragement of Athens and Sparta, they engaged in a long and sanguinary war with Thebes and her allies. It was during this contest that Philip first gained a footing in Thessaly. This he effected by aiding certain of the Thessalian nobles against the tyrants of Pheræ, who had the Phocians and Athenians for their allies. This movement brought Philip into collision with the Athenians. When that republic attempted, together with the people of Methone, to thwart the influence of Philip on the coasts of Thrace, he suddenly made a descent upon that place, and made it his own after a determined siege, in which he lost an eye by an arrow shot.

During all this time the Phocian war raged with the greatest fury, and involved in it all the states of Greece. Lycophron, one of the Thessalian tyrants whom Philip had formerly deprived of his authority, had again found means to re-establish himself; and his countrymen having taken part with the Phocians, Lycophron called in Onomarchus, the Phocian general, to protect him against the power of Philip, by whom he was sensible that he would soon be attacked. The king accordingly marched into Thessaly with a considerable army, and defeated Phyllus, the brother of Onomarchus, whom the latter had sent into the country with a detachment of 7000 men. After this he besieged and took the city of Pegasus, driving the enemy towards the frontiers of Phocis. Onomarchus then advanced with the whole army; and Philip, though inferior in numbers, did not decline the engagement. The Phocians at first gave ground, on which the Macedonians pursued, in good order; but coming near a precipice, on the top of which Onomarchus had posted a detachment of soldiers, the latter rolled down stones and fragments of the rock in such a manner as did dreadful execution, and threw them into the utmost disorder. Philip, however, rallied his troops with great presence of mind, and prevented the Phocians from gaining any further advantage; saying, as he withdrew his troops, that they did not retreat through fear, but only like rams, in order to strike with the greater vigour. Nor was he long before he made good his assertion; for, having recruited his army with the greatest expedition, he returned into Thessaly at the head of 20,000 foot and 500 horse, and was there met by Onomarchus. The Macedonians at this time were superior in number to their enemies; and Philip, moreover, took care to remind them that their quarrel was that of heaven, and that their enemies had been guilty of sacrilege, by profaning the temple of Delphi. That they might be still more animated in the cause, he put crowns of laurel on their heads. Thus fired with enthusiasm, and having besides the advantage of numbers, the Phocians were altogether unable to withstand them. They threw away their arms and fled towards the sea, where they expected to have been relieved by Chares, who, with the Athenian fleet, was

Macedonia. near to the shore; but in this they were disappointed, for he made no attempt to save them. Upwards of 6000 perished in the field of battle or in the pursuit, and 3000 were taken prisoners. The body of Onomarchus being found amongst the slain, was, by order of Philip, hung upon a gibbet, as a mark of infamy, on account of his having polluted the temple; and the bodies of the rest were thrown into the sea, as being all partakers of the same crime.

The Olynthians now applied to Athens for aid against the ambitious schemes of their former ally of Macedonia: a call to which the Athenians, moved by the voice of Demosthenes, gave a ready response, and sent successive reinforcements to their relief. Philip ultimately defeated this allied force, and subsequently captured Olynthus (B.C. 347). The Athenians and Macedonians concluded a treaty of peace the following year, from which the Phocian allies of Athens, by the unprincipled dexterity of Philip, were excluded. That brave and unfortunate people now found themselves at the mercy of their more powerful enemies. The Thebans, who had borne an unequal share in the conflict, now in their hour of need solicited the willing aid of Philip. Passing the unguarded defiles of Thermopylæ, he made a swift descent upon Greece proper, and from the misconduct and treachery of the Phocian leaders, was entirely successful. The Phocians were compelled to surrender at mercy, and the Amphictyons, in solemn council, decreed that their towns should be destroyed, their inhabitants disarmed and heavily assessed, and that their Delphian privileges and votes in the council should revert to the pious Macedonian. Thus ended the Sacred War (B.C. 346).

Athens and Macedonia.

Athens and Macedon were now gradually approaching a collision: the former had for a lengthened period struggled for the independence of Greece, while the latter aspired to general supremacy in her government and councils. But Athens had not only to maintain a contest with the Macedonian,—she had discontented factions within her own borders more dangerous to her safety than even her northern foe. There was an aristocratic and a democratic party. The voice of the former was for peace, that of the latter for war. The peace party regarded resistance against such odds as fatal. They looked on the democrats with contempt; and with a painful assurance of the utterly degenerate character of that faction, probably saw no cure for the evils of intestine strife except a diversion against Persia, headed by Philip of Macedon. The peace party was led by the tried patriots Isocrates and Phocion; but there were men of a very different stamp who found shelter among them. The pay of Philip had wrought its way among the base and the treacherous. Chief of these hirelings were the orators Æschines and Demades. The democratic party, on the other hand, eager for the license and plunder which hang in the skirts of war, were guided by the base Chares and the mercenary Charidemus. But this party was fortunate enough to have among its ranks a patriot of generous enthusiasm and of noble independence, who, while he was alarmed at the unscrupulous ambition of Philip, was yet determined to offer a brave resistance to the formidable front of the aspiring king. This was none other than the celebrated Demosthenes. (See DEMOSTHENES.)

After the Phocian war had been brought to a close, Philip directed his efforts to the consolidation of his empire in the north of Greece. The towns of the Propontis and the Thracian Chersonese he soon made his own. He invested Perinthus and Byzantium; but the voice of Demosthenes was now raised against him. Phocion, with an armament of Athenians, bore down upon him and compelled him to raise the siege of those cities. But the triumph of the orator and the disappointment of the prince were alike momentary. The one had to act upon a fickle and divided multitude, the other upon splendidly disciplined armies. The plans of the one were open to all, those of

the other were shrouded in the profoundest mystery till the moment for action brought them to the light. In the following year, appointed by the obsequious Amphictyons to chastise the people of Amphissa for cultivating certain devoted lands, Philip, after reducing that city, seized Elateia at the head of 32,000 veteran soldiers. Alarm and dismay seized the Athenians, but the eloquence of Demosthenes, by gaining over the Thebans and Corinthians, revived the expiring courage of the republicans. Consummate generalship and discipline, however, proved more than a match for numerical superiority, and the fatal battle of Chæroneia (B.C. 338) saw the confederates defeated, and the liberties of ancient Greece extinguished for ever. Nothing attested more the efficiency of Philip's improved *phalanx* than this bloody victory. (For a full account of this military organization, see ARMY; also, Grote's *History of Greece*, vol. xii., c. 92.) After the battle, Philip immediately stopped the slaughter; and (if we may credit the story) when, on revisiting the field after a night's carouse, he beheld the Sacred Band of the Thebans lying in swathes where the scythe of war had mowed them down, he burst into tears, and exclaimed,—“Perish they who imagine those to have done or suffered wrong.” This burst of generous feeling did not, however, extend to the Thebans who survived. The hostile party in their city he treated with great harshness and severity, while he conducted himself towards the Athenians with the utmost clemency. (See Grote's *History of Greece*, vol. xi., c. 90.)

Battle of Chæroneia.
B.C. 338.

To all appearance the great object of Philip's ambition was now within his grasp. In consideration of the wrongs which Persia had inflicted upon Greece, it was resolved in the assembly that war should be declared on a national scale against that power, with the King of Macedonia as the commander of the expedition. But another was destined to enjoy the laurels which Philip had all but won. While celebrating the nuptials of his daughter Cleopatra with the King of Epirus, a young Macedonian of his own body-guard, named Pausanias, stabbed him to the heart. As the assassin died on the spot, his motive for the deed could not be ascertained; but it was generally supposed to have arisen from personal revenge, on the king's refusal to redress a foul insult received from the uncle of the queen. Some say he was secretly urged to commit the deed by Olympias (now superseded by the new queen, Cleopatra), and her son Alexander, who had quarrelled with his father a short time previously. Thus fell this aspiring king at the early age of forty-seven (B.C. 336), full of life and energy, with a vista of glory opening up before him. Despite the scantiness of our information respecting him, the great outlines of his character and achievements can be easily traced. He raised the Macedonian kingdom from a narrow territory to a vast possession, reaching from the shores of the Propontis to the Thermaic Gulf. He was possessed of fine political and military talent, and fortune smiled on his endeavours; but the splendour of his name is dimmed by base perjury and gross intemperance. Theopompus, his contemporary and warm admirer, stigmatizes his conduct as follows:—“His Macedonian and Grecian body-guard, 800 in number, was a troop in which no decent man could live; distinguished indeed for military bravery and aptitude, but sated with plunder, and stained with such shameless treachery, sanguinary rapacity, and unbridled lust, as befitted only Centaurs and Læstrygons.” There can be little doubt that the hopeless degeneracy of Grecian spirit and national feeling acted as a foil to Philip's brilliant talent for conquest.

No sooner did the news of Philip's death reach Athens, than, as if all danger had been past, the inhabitants showed the most extravagant signs of joy. Demosthenes and his party put on chaplets of flowers, and behaved as if they had gained a great victory. Phocion reproved them for this madness, bidding them remember that “the army which

Joy of the Athenians.

Macedonia had beaten them at Cheronæa was lessened but by one." This reproof, however, had very little effect. The people heard with pleasure all the harsh things which the orators could say of the young Alexander, King of Macedonia, whom they represented as a giddy, wrong-headed boy, ready to grasp all things in his imagination, and able to perform nothing. The affairs of Macedonia indeed were in a very distracted state on the accession of Alexander; for all the neighbouring nations had the same notion of the young king with the Athenians, and, being irritated by the usurpations of Philip, immediately revolted, and the states of Greece entered into a confederacy against him. The Persians had been contriving how to transfer the war to Macedonia; but as soon as the news of Philip's death reached them, they behaved as if all danger had been terminated. At the same time, Attalus, one of the Macedonian commanders, aspired to the crown, and sought to draw off the soldiers from their allegiance.

Alexander
declared
general of
Greece.
B.C. 336.

In the councils held upon this occasion, Alexander's best friends advised him rather to make use of dissimulation than force, and to try to cajole those whom they thought he could not subdue. These advices, however, were ill suited to the temper of their monarch. He thought that vigorous measures only were proper, and therefore immediately led his army into Thessaly. Here he harangued the princes so effectually, that he thoroughly gained them over to his interest, and was by them declared general of Greece; upon which he returned to Macedonia, where he caused Attalus to be seized and put to death.

In the spring of the next year (335 before Christ), Alexander resolved to subdue the Triballians and Illyrians, who inhabited the countries now called Bulgaria and Sclavonia, and had been very formidable enemies to the Macedonian power. In this expedition he discovered, though then but twenty years of age, a surprising degree of military knowledge. Having advanced to the passes of Mount Hæmus (the Balkan), he learned that the barbarians had posted themselves in the most advantageous manner. Upon the tops of the cliffs, and at the head of every passage, they had placed their carriages and waggons in such a manner as to form a kind of parapet, with their shafts inwards, that when the Macedonians should have half ascended the rock, they might be able to push these heavy carriages down upon them; and they reckoned the more upon this contrivance, because of the close order of the phalanx, which, they imagined, would be terribly exposed by the soldiers wanting room to stir, and thereby to avoid the falling waggons. But Alexander, having directed his heavy-armed troops to march, gave orders that, where the way would permit, they should open to the right and left, and suffer the carriages to go through; but that, in the narrow passes, they should throw themselves on their faces with their shields behind them, that the carts might run over them. This had the desired effect, and the Macedonians reached the enemy's works without the loss of a man. The dispute was then quickly decided. The barbarians were driven from their posts with great slaughter, and left behind them a considerable booty for the conquerors.

Thebes
taken and
destroyed.

The next exploits of Alexander were against the Getæ, the Tanlantii, and some other nations inhabiting the country upon the other side of the Danube. These he also overcame; showing in all his actions the most perfect skill in military affairs, joined with the greatest valour. In the meantime, however all Greece was thrown into commotion by a report which had been confidently spread abroad, that the king was dead in Illyria. The Thebans, on this news, seized Amyntas and Timolaus, two eminent officers in the Macedonian garrison which held their citadel, dragged them to the market-place, and put them to death without either form of process or any crime being alleged against them. Alexander, however, did not suffer the Thebans to

remain long in their mistake. He marched with such expedition, that in seven days he reached Pallene in Thessaly; and in six days more he entered Bœotia, before the Thebans had any intelligence of his having passed the Straits of Thermopylæ. Even then they would not believe that the king was alive, but insisted that the Macedonian army was command by Antipater, or by one Alexander the son of Æropus. The rest of the Greeks, however, were not so hard of belief, and therefore sent no assistance to the Thebans, who were thus obliged to bear the consequences of their own folly and obstinacy. Their city was taken by assault, and the inhabitants were for some hours massacred without distinction of age or sex, after which the houses were demolished, excepting that of Pindar, the famous poet, which was spared out of respect to the merit of its owner, and because he had celebrated Alexander, King of Macedonia. The lands, except those destined to religious uses, were shared amongst the soldiers, and all the prisoners sold as slaves, by which 440 talents were brought into the king's treasury.

By this severity the rest of the Grecian states were so thoroughly humbled, that they thought no more of making any resistance, and Alexander had nothing further to hinder him from pursuing his favourite project of invading Asia. Very little preparation was necessary for the Macedonian monarch, who went as to an assured conquest, and reckoned upon being supplied chiefly by the spoils of his enemies. Historians are not agreed as to the number of his army. Arrian says that there were thirty thousand foot and five thousand horse. Plutarch tells us that according to a moderate computation, Alexander had thirty thousand foot and five thousand horse; and that according to the largest estimate, he had thirty-four thousand foot and four thousand horse. As to his fund for the payment of the army, Aristobolus says it was but seventy talents; and Onesicritus, who was also present in this expedition, not only takes away the seventy talents, but affirms that the king was two hundred in debt. As for provisions, there was just sufficient for a month and no more; and to prevent disturbances, Antipater was left in Macedonia with twelve thousand foot and fifteen hundred horse.

The army having assembled at Amphipolis, Alexander marched thence to the mouths of the River Strymon; then crossing Mount Pangæus, he took the road to Abdera. Crossing the River Ebrus, he proceeded through the country of Pædis, and in twenty days reached Sestos; thence he marched to Eleusa, where he sacrificed on the tomb of Protesilaus, because he was the first amongst the Greeks who at the siege of Troy set foot upon the Asiatic shore. He did this that his landing might be more propitious than that of the hero to whom he sacrificed, who was soon afterwards slain. The greatest part of the army, under the command of Parmenio, embarked at Sestos, on board of a hundred and sixty galleys of three benches of oars, besides small craft. Alexander himself sailed from Eleusa; and when he was in the middle of the Hellespont, offered a bull to Neptune and the Nereids, pouring forth at the same time a libation from a golden cup. When he drew near to the shore, he launched a javelin, which stuck in the earth; then, in complete armour, he leaped upon the strand; and having erected altars to Jupiter, Minerva, and Hercules, he proceeded to Ilium. Here again he sacrificed to Minerva; and taking down some arms which had hung in the temple of that goddess since the time of the Trojan war, he consecrated his own in their stead. He sacrificed also to the ghost of Priam, to avert his wrath on account of the descent which he himself claimed from Achilles.

Alexander
sets out on
his expedition.

In the meantime the Persians had assembled a great army in Phrygia, amongst whom was one Memnon, a Rhodian, the best officer in the service of Darius. Memnon gave it as his opinion that they should burn and destroy all the country round, that they might deprive the Greeks of

Granicus.

Macedonia. the means of subsisting, and then transport a part of their army into Macedonia. But the Persians, depending on their cavalry, rejected this salutary advice, and posted themselves along the river Granicus, in order to await the arrival of the Greeks. Alexander, as soon as he had performed all the ceremonies which he judged necessary, marched directly towards the enemy. In the engagement which ensued on the banks of that river, the Persians were defeated, and Alexander became master of all the neighbouring country, which he immediately began to take care of, as if it had been part of his hereditary dominions. The city of Sardis was immediately delivered up; and here Alexander built a temple to Jupiter Olympius. After this, he restored the Ephesians to their liberty, ordered the tribute which they formerly paid to the Persians to be applied towards the rebuilding of the magnificent temple of Diana, and having settled the affairs of the city, marched against Miletus. This place was defended by Memnon with a considerable body of troops, who had fled thither after the battle of Granicus, and therefore made a vigorous resistance. The fortune of Alexander, however, prevailed; and the city was soon reduced, though Memnon with part of the troops escaped to Halicarnassus. After this, the king dismissed his fleet,—a proceeding for which various causes have been assigned, though it is probable that the chief reason was to show his army that their only resource now lay in subverting the Persian empire.

Subsequent proceedings.

Almost all the cities between Miletus and Halicarnassus submitted as soon as they heard that the former was taken; but Halicarnassus, where Memnon commanded with a very numerous garrison, made an obstinate defence. Nothing, however, was capable of resisting the Macedonian army. Memnon was at last obliged to abandon the place; upon which Alexander took and razed the city of Tralles in Phrygia, received the submission of several princes tributary to the Persians; and having destroyed the Marmarians, a people of Lycia, who had fallen upon the rear of his army, put an end to the campaign; after which he sent home all the new-married men, which endeared him more to his soldiers than almost any other action of his life.

As soon as the season would permit, Alexander quitted the province of Phaselus; and having sent part of his army through the mountainous country to Perga, by a short but difficult road, took his route by a certain promontory, where the way is altogether impassable except when the north winds blow. At the time of the king's march the south wind had held for a long time; but of a sudden it changed, and blew from the north so violently, that, as he and his followers declared, they obtained a safe and easy passage through divine assistance. He continued his march towards Gordium, a city of Phrygia; the enemy having abandoned the strong pass of Telmissus, through which it was necessary for him to march. When he arrived at Gordium, and found himself under the necessity of staying there some time till the several corps of his army could be reunited, he expressed a strong desire of seeing Gordius's chariot, and the famous knot in the harness, of which such strange stories had been published to the world. The cord in which this knot was tied was made of the inner rind of the cornel tree; and no eye could perceive where it began or ended. Alexander, when he could find no possible way of untying, and yet was unwilling to leave it tied, lest it should cause some fears in the breasts of his soldiers, is said by some authors to have cut the cords with his sword, saying, "It matters not how it is undone." A great tempest of thunder, lightning, and rain, happening the succeeding night, it was held declarative of the true solution of this knot, and that Alexander would become master of Asia.

The king having left Gordium, marched towards Cilicia, where he was attended with his usual good fortune, the Persians abandoning all the strong passes as he advanced.

As soon as he entered the province, he received advice that Arsames, whom Darius had made governor of Tarsus, was about to abandon it, and that the inhabitants were very apprehensive that he intended to plunder them before he withdrew. To prevent this, the king marched incessantly, and arrived just in time to save the city. But his saving it had well nigh cost him his life; for, either through the excessive fatigue of marching, as some say, or, according to others, by his plunging when very hot into the River Cydnus, which, as it runs through thick shades, has its waters excessively cold, he fell into such a distemper as threatened immediate dissolution. Philip the Acarnanian alone preserved self-command enough to examine the nature of the king's disease, the worst symptom of which was a continual shivering, which he removed by means of a potion, and in a short time the king recovered his usual health.

Alexander's sickness and recovery.

Soon after Alexander's recovery, he received the agreeable news that Ptolemy and Asander had defeated the Persian generals, and made great conquests on the Hellespont; and a little after that he met the Persian army at Issus, commanded by Darius himself. A bloody engagement ensued, in which the Persians were defeated with great slaughter (B.C. 333). The consequences of this victory were very advantageous to the Macedonians. Amongst the number of those places which, within a short space after the battle of Issus, sent deputies to submit to the conqueror, was the city of Tyre. The king, whose name was Azelmicus, was absent in the Persian fleet; but his son was amongst the deputies, and was very favourably received by Alexander. The king probably intended to confer particular honours upon the city of Tyre, for he acquainted the inhabitants that he would come and sacrifice to the Tyrian Hercules, the patron of their city, to whom they had erected a most magnificent temple. But these people, like most other trading nations, were far too suspicious to think of admitting such an enterprising prince with his troops within their walls. Alexander then assembled a council of war, in which he insisted strongly on the disaffected state of Greece (for most of the Grecian states had sent ambassadors to Darius, to enter into a league with him against the Macedonians), the power of the Persians by sea, and the folly of carrying on the war in distant provinces, whilst Tyre was left unreduced behind them; he also remarked, that if once this city was subdued, the sovereignty of the sea would be transferred to them, because it would fix their possession of the coasts; and as the Persian fleet was composed chiefly of tributary squadrons, those tributaries would fight the battles, not of their late, but of their present masters.

For these reasons the siege of Tyre was resolved on. Tyre taken The town was not taken, however, without great difficulty, and destroyed. which provoked Alexander to such a degree that he treated the inhabitants with the greatest cruelty. After the reduction of Tyre, Alexander, though the season was already far advanced, resolved to make an expedition into Syria; and in his way thither proposed to chastise the Jews, who had highly offended him during the siege of Tyre; for when he sent to them to demand provisions for his soldiers, they answered, that they were the subjects of Darius, and bound by oath not to supply his enemies. The king, however, was pacified by their submission, and not only pardoned them, but conferred many privileges upon them.

From Jerusalem Alexander marched directly to Gaza, Egypt submitted. The only place in that part of the world which still held out for Darius. The governor Batis defended the place with great valour, and several times repulsed his enemies; but at last it was taken by storm, and all the garrison slain to a man; and this secured to Alexander an entrance into Egypt, which having before been very impatient of the Persian yoke, admitted the Macedonians peaceably. Here the king laid the foundations of the city of Alexandria,

Macedonia. which for many years afterwards continued to be the capital of the country. Whilst he remained here, he also formed the singular design of visiting the temple of Jupiter Ammon. As to the motives by which he was induced to take this extraordinary journey, authors are not agreed; but certain it is, that he hazarded himself and his troops in the highest degree, there being two dangers in this march, which, with the example before him of Cambyses, who lost the greater part of his army in it, might have terrified anybody but Alexander. The first was the want of water, which, in the sandy deserts surrounding the temple, is nowhere to be found; the other, the uncertainty of the road from the fluctuation of the sands, which, changing their situation every moment, leave the traveller neither a road to walk in, nor a mark to march by. These difficulties, however, Alexander overcame, though not without a miraculous interposition, as is pretended by all his historians.

Battle of Arbela.

Alexander having consulted the oracle, and received a favourable answer, returned to pursue his conquests. Having settled the government of Egypt, he appointed the general rendezvous of his forces at Tyre. Here he met with ambassadors from Athens, requesting him to pardon such of their countrymen as he found serving the enemy. The king being desirous to oblige such a famous state, granted their request, and also sent a fleet to the coast of Greece, to prevent the effects of some commotions which had lately happened in Peloponnesus. He then directed his march to Thapsacus; and having passed the Euphrates and Tigris, met with Darius near Arbela (*Erbil*), where the Persians were again overthrown with prodigious slaughter, and by this victory Alexander became in effect master of the Persian empire.

Babylon, Susa, and Persepolis reduced.

After this important victory, Alexander marched directly to Babylon, which was immediately delivered up, the inhabitants being greatly disaffected to the Persian interest. After thirty days' stay in this country, the king marched to Susa, which had already surrendered to Philoxenus; and here he received the treasures of the Persian monarch, amounting, according to the most generally received account, to 50,000 talents. Having received also at this time a supply of 6000 foot and 500 horse from Macedonia, he set about reducing the nations of Media, amongst whom Darius had retired. He first reduced the Uxians, and having forced a passage to Persepolis, the capital of the empire, he, like a barbarian, destroyed the stately palace there, a pile of building not to be equalled in any part of the world, after having given up the city to be plundered by his soldiers. In the palace he found 120,000 talents, which he appropriated to his own use, and caused immediately to be carried away upon mules and camels; for he had such an extreme aversion to the inhabitants of Persepolis, that he determined to leave nothing valuable in that city.

Alexander pursues Darius, who is murdered by Bessus.

During the time that Alexander remained at Persepolis, he received intelligence that Darius remained at Ecbatana, the capital of Media, upon which he pursued him with the greatest expedition, marching at the rate of nearly 40 miles a day. In fifteen days he reached Ecbatana, where he was informed that Darius had retired from thence five days before, with an intent to pass into the remotest provinces of his empire. At this place the Thessalian cavalry and many of the allies, having terminated their service, were dismissed with full pay. Some who preferred it were enrolled as volunteers. The king bought the horses of the Thessalians, who, with the rest of the Greeks, were conducted in safety to the Mediterranean.

On receiving fresh information concerning the state of Darius' affairs, the king again set out in pursuit of him, advancing as far as Rhagæ, a city one day's journey from the Caspian Gates. There he understood that Darius had some time before passed those straits; and this information leaving him again without hopes, he halted for five

days. Oxidates, a Persian whom Darius had left prisoner at Susa, was made governor of Media, whilst the king departed on an expedition into Parthia. The Caspian Gates he passed immediately without opposition, and he then gave directions to his officers to collect a quantity of provisions sufficient to serve his army on a long march through a wasted country. But before his officers could accomplish these commands, the king received intelligence that Darius had been murdered by one of his own subjects, Bessus, the governor of Bactria.

As soon as Alexander had collected his forces together, Hyrcania and settled the government of Parthia, he entered Hyrcania; and having, according to his usual custom, committed the greater part of his army to the care of Craterus, he, at the head of a choice body of troops, passed through certain craggy roads, and, before the arrival of Craterus, who took an open and easy path, struck the whole provinces with such terror, that all the principal places were immediately put into his hands; and soon afterwards the province of Aria also submitted, and the king continued Satibarzanes, the governor, in his employment. The reduction of this province completed the conquest of Persia; but the ambition of Alexander to become master of every nation of which he had the least intelligence, induced him to enter the country of Mardi, merely because its rocks and barrenness had hitherto prevented any one from conquering, or, indeed, from attempting to conquer it. This conquest however, he easily accomplished, and obliged the whole nation to submit to his pleasure. But in the meantime disturbances began to arise in Alexander's new empire, and amongst his troops, which all his activity could not thoroughly suppress. He had scarcely left the province of Aria, when he received intelligence that the traitor Bessus had caused himself to be proclaimed king of Asia by the name of Artaxerxes; and that Satibarzanes had joined him, after having massacred all the Macedonians who had been left in the province. Alexander appointed one Arsames governor in the room of Satibarzanes, and marched thence with his army against the Zarangæ.

The immense treasure which the Macedonians had acquired in the conquest of Persia now began to affect their discipline. The king himself was of a most generous disposition, and liberally bestowed his gifts on those around him; but they made a bad use of his bounty, and foolishly indulged in those vices by which the former possessors of that wealth had lost it. The king did all in his power to discourage the lazy and inactive pride which now began to show itself amongst his officers; but neither his discourses nor his example had any considerable effect. The form of his civil government resembled that of the ancient Persian kings; in military affairs, however, he strictly preserved the Macedonian discipline; but then he made choice, out of the provinces, of 30,000 boys, whom he caused to be instructed in the Greek language, and directed to be brought up in such a manner as that from time to time he might with them recruit the phalanx. The Macedonians observed with great concern these extraordinary measures, which suited very ill with their gross understandings; for, after all the victories they had gained, they expected to be absolute lords of Asia, and to possess not only the riches of its inhabitants, but to rule the inhabitants themselves; whereas they now found that Alexander meant no such thing, but that, on the contrary, he conferred governments, offices at court, and all other marks of confidence and favour, indiscriminately both on Greeks and Persians. From this time also the king seems to have given proofs of a cruelty which he had never shown before. Philotas, his most intimate friend, was seized, tortured, and put to death, for a conspiracy of which it could never be proved that he was guilty; and soon afterwards Parmenio, the father of the former, and some others, were executed with-

Macedonia. out any crime at all, real or alleged. These things very much disturbed the army. Some of them wrote home to Macedonia respecting the king's suspicions of his friends, and his disposition to hunt out enemies at the very extremities of the world. Alexander having intercepted some of these letters, and procured the best information he could concerning their authors, picked out these dissatisfied people, and having disposed them into a corps, gave it the title of the "turbulent battalion," hoping by this means to prevent the spirit of disaffection from pervading the whole army. As a further precaution against any future conspiracy, Alexander thought fit to appoint Hephæstion and Clytus generals of the auxiliary horse; being apprehensive, that if this authority was lodged in the hands of a single person, it might prompt him to dangerous undertakings, and at the same time furnish him with the means of carrying them into execution. To keep his forces in action, he suddenly marched into the country of the Euergetæ, or Benefactors, and found them full of the kind and hospitable disposition for which that name had been bestowed on their ancestors by the first Cyrus; he therefore treated them with great respect, and at his departure added some lands to their dominions, which lay contiguous, and which for that reason they had requested of him.

Alexander spent the greater part of the autumn and winter in the reduction of the region around Dragiana, the modern Afghanistan, Scistan, and western Cabool. Any resistance he met with was fitful and desultory; but his soldiers suffered severely from cold and want of food. Arrian remarks, after his own fashion,—“Alexander moved forward not a whit the less; with difficulty, indeed, through deep snow, and without provisions; but still he moved on.” He founded a new city called *Alexandria ad Caucasum* (Begram? See Masson's *Narrative of Journeys in Afghanistan, &c.*, vol. iii., c. 7), at one of the southern passes of the Hindoo-Koosh. Here he planted 7000 old Macedonian soldiers as colonists. By a fifteen days' march through snow he crossed the vast mountain range of the Hindoo-Koosh, and entered the region of Bactria.

Bessus reduced and put to death.

Bessus, who had assumed the name of Artaxerxes, when he was assured that Alexander was marching towards him, immediately began to waste all the country between Paropamisus and the River Oxus, which river he passed with all his forces, and then burned all the vessels he had made use of for transporting them, retiring to Nautaca, a city of Sogdia, fully persuaded that, by the precautions he had taken, Alexander would be compelled to give over his pursuit. This conduct of his, however, disheartened his troops, and gave the lie to all his pretensions; for he had affected to censure Darius' conduct, and had charged him with cowardice, in not defending the River Euphrates and Tigris, whereas he now quitted the banks of the most defensible river perhaps in the whole world. As to his hopes, though it cannot be said they were ill founded, yet they proved absolutely vain; for Alexander, continuing his march, notwithstanding the hardships his soldiers sustained, reduced all Bactria under his obedience, particularly the capital Bactria and the strong castle Aornus. In the latter he placed a garrison under the command of Archelaus, but the government of the province he committed to Artabazus. He then continued his march to the River Oxus, on the banks of which, when he arrived, he found it three-quarters of a mile in breadth, its depth more than proportional to its breadth, its bottom sandy, its stream so rapid as to render it almost unnavigable, and neither boat nor tree in its neighbourhood; so that the ablest commanders in the Macedonian army were of opinion that the army would be obliged to march back. The king, however, having first sent away, under a proper escort, all his infirm and worn-out soldiers, that they might be conducted safely to the seaports, and thence transported

to Greece, devised a method of passing this river without either boat or bridge, by causing the hides which covered the soldiers' tents and carriages to be stuffed with straw, and then tied together, and thrown into the river. Having crossed the Oxus, he marched directly towards the camp of Bessus, where, when he arrived, he found it abandoned; but at the same time received letters from Spitamenes and Dataphernes, who were the chief commanders under Bessus, signifying, that if he would send a small party to receive Bessus, they would deliver him into his hands; which they did accordingly, and the traitor was immediately put to death, after cruel mutilation.

A supply of horses having now arrived, the Macedonian Alexander cavalry were remounted. Alexander continued his march passes the to Maracanda, the capital of Sogdia, whence he advanced Indus. to the River Iaxartes. Here he performed extraordinary exploits against the Scythians, from whom, however, though he overcame them, his army suffered much; and the revolted Sogdians, being headed by Spitamenes, gave him a great deal of trouble. Here also he married Roxana, the daughter of Oxyartes, a prince of the country whom he had subdued. But during these expeditions, the king greatly disgusted his army by the murder of his friend Clytus in a drunken quarrel at a banquet, and by his extravagant vanity in claiming divine honours. At last he arrived at the River Indus, where Hephæstion and Perdikkas had already provided a bridge of boats for the passage of that river. He then ordered the vessels of which his bridge had been composed to be taken to pieces, that they might be brought to the Hydaspes (*Jelum*) where he was informed that Porus with a great army lay encamped to dispute his passage.

Alexander experienced no resistance till he met the brave Indian prince, Porus, who, with a formidable force, stood on the further side of a river, prepared to dispute his passage. The Macedonians, by a series of skilful manoeuvres, eluded the watchfulness of the Indians, crossed the river at a point above where the army lay, and completely overthrew Porus and his brave host. This gigantic prince, who was mounted on an elephant, moved about among his scattered troops with signal spirit and intrepidity, cheering on the dispirited, and reviving the expiring courage of the wavering. He saw two of his sons fall by his side, and had himself received a severe wound; yet he fought on almost single-handed with the fierce energy of proud despair. It was with considerable difficulty that Alexander succeeded in preserving the life of this invincible hero. When Porus was brought before him, Alexander, over whose passionate nature external impressions exercised a strong influence, was much struck with his handsome figure and undaunted mien. He showed this prince the utmost generosity, not only by reinstating him in his kingdom, but also by extending its boundaries; and Porus proved in return a faithful ally to Alexander. “This was,” says Grote, “the greatest day of Alexander's life, if we take together the splendour and difficulty of the military achievement, and the generous treatment of his conquered opponent.”

Passes the Hydaspes, and defeats Porus.

To perpetuate the memory of this victory, Alexander ordered two cities to be erected; one, on the field of battle, which he named Nicæa, the other on the opposite side of the river, which he called Bucephala, in honour of his horse Bucephalus, who died here, as Arrian says, of mere old age, being on the verge of thirty. All the soldiers who fell in the battle he buried with great honours, offered solemn sacrifices to the gods, and exhibited pompous shows on the banks of the Hydaspes, where he had forced his passage. He then entered the territories of the Glaucæ, in which there were thirty-seven good cities and a multitude of populous villages. All these were delivered up to him without fighting; and as soon as he received them, he presented them

Macedonia. to Porus, and having reconciled him to Taxiles, he sent the latter home to his own dominions. About this time ambassadors arrived from several Indian princes with their submissions; and Alexander having conquered the dominions of another Porus, which lay on the Hydraotes, a branch of the Indus, added them to those of Porus his ally.

In the middle of all this success, however, news arrived that the Cathei, Oxydracæ, and the Malli, the most warlike nations of India, were confederated against the Macedonians, and had drawn together a great army. The king immediately marched to give them battle, and in a few days reached a city called Sangala, seated on the top of a hill, and having a fine lake behind it. Before this city the confederate Indians lay encamped, having three circular lines of carriages locked together, and their tents pitched in the centre. These defences being forced, they took refuge within their walls, and resolved to evacuate by night. Informed by deserters of this project, Alexander succeeded in defeating it. Next day he stormed the town, killing, as Arrian records, 17,000 Indians, and taking 70,000 captives. His own loss was less than 100 killed and 1200 wounded. After razing Sangala, he annexed the territory to the kingdom of his Indian ally.

Alexander, still unsated with conquest, now prepared to pass the Hyphasis (*Sutlege*). The chief reason which induced him to think of this expedition, was the information he had received of the state of the countries beyond that river. He was told that they were in themselves rich and fruitful; that their inhabitants were not only a very martial people, but very civilized; that they were governed by the nobility, who were themselves subject to the laws; and that as they lived in happiness and freedom, it was likely they would fight obstinately in defence of those blessings. He was further told, that amongst these nations there were the largest, strongest, and most useful elephants bred and tamed; and was therefore fired with an earnest desire of reducing such a bold and brave people under his rule, and of attaining to the possession of the many valuable things that were said to be amongst them. As exorbitant, however, as his personal ambition was, he found it impossible to infuse any part of it into the minds of his soldiers, who were so far from wishing to triumph over new and remote countries, that they were highly desirous of leaving those that they had already conquered. When, therefore, they were informed of the king's intentions, they privately consulted together in the camp about the situation of their own affairs. At this consultation, the gravest and best of the soldiers lamented that they were made use of by their king, not as lions, who fall fiercely upon those who have injured them, but as mastiffs, who fly upon and tear those who are pointed out to them as enemies. The rest were not so modest, but expressed themselves roundly against the king's humour for leading them from battle to battle, from siege to siege, and from river to river; protesting that they would follow him no farther, nor lavish their blood any longer to purchase for him the fame he coveted. Alexander had too much penetration not to perceive that his troops were very uneasy. He therefore harangued them from his tribunal; but though his eloquence was great, and the love his army had for him was yet very strong, they did not relent. For some time the soldiers remained sullen and silent; and at last turned their eyes on Cœnus, an old and experienced general, whom Alexander loved, and in whom the army put great confidence. He had the generosity to undertake their cause, and told Alexander frankly, "that men endured toil in hopes of repose; that the Macedonians were already much reduced in their numbers; that of those who remained, the greater part were invalids; and that they expected, in consideration of their former services, that he would now lead them back to their native country, an act which, of all others, would

most contribute to his own great designs, since it would encourage the youth of Macedonia, and even of all Greece, to follow him in whatever new expedition he pleased to undertake." The king was far from being pleased with this speech of Cœnus, and much less with the disposition of his army, which continued in a deep silence. He therefore dismissed the assembly. But next day he called another, in which he told the soldiers plainly that he would not be driven from his purpose; that he would proceed in his conquests with such as should follow him voluntarily; and that, as for the rest, he would not detain them, but would leave them at liberty to go home to Macedonia, where they might publish, "that they had left their king in the midst of his enemies." Even this expedient had no success; his army was so thoroughly tired with long marches and desperate battles, that they were determined to advance no further; upon which Alexander retired to his tent, where he refused to see his friends, and evinced the same gloomy temper that reigned amongst his troops.

For three days things remained in this situation. At last Alexander the king suddenly appeared; and, as if he had been fully determined to pursue his first design, he gave orders to sacrifice for the good success of his new undertaking. But Aristander, the augur, reported that the omens were altogether inauspicious; upon which the king said, that since his proceeding farther was neither pleasing to the gods nor grateful to his army, he would return. When this was rumoured amongst the army, they assembled in great numbers about the royal tent, saluting the king with loud acclamations, wishing him success in all his future designs, and giving him at the same time hearty thanks, inasmuch as "he who was invincible had suffered himself to be overcome by their prayers." A stop being thus put to the conquests of Alexander, he determined to make the Hyphasis the boundary of his dominions; and having erected twelve altars of an extraordinary magnitude, he sacrificed upon them, after which he exhibited shows in the Grecian manner; and, having added all the conquered country in these parts to the dominions of Porus, he began to return. Having arrived at the Hydaspes, he made the necessary preparations for sailing down the Indus to the ocean. For this purpose, he ordered vast quantities of timber to be felled in the neighbourhood of the Hydaspes, through which he was to sail into the Indus; and by the beginning of November, he, with a fleet of 2000 boats, began his voyage down the Hydaspes. Craterus and Hephestion, with their divisions, moved down the banks of the river. The king kept on board the fleet, which was commanded by Nearchus. The main stream of the Indus was gradually reached, down which they sailed to the ocean. The entire voyage occupied nine months, from November 326 B.C. to August 325 B.C. But it is not to be supposed that Alexander contented himself with the unbroken monotony of this tedious expedition. All tribes bordering on the river which did not offer voluntary submission, were attacked, subdued, and slaughtered. Among these were the Malli. Attacking this brave people with his accustomed energy, Alexander drove them within the walls of their strongest city. Having pursued them to the gates, the king, in his hot impatience at the tardy arrival of the troops with the scaling-ladders, managed to mount the wall, and after striking down its defenders, flung himself into the fortress, where he made his way, single-handed, for a time against all opposition. He was on the point of falling, however, from a severe wound, when his soldiers dashed in, rescued their brave general, and took the citadel. The Indians were now slaughtered without mercy; but Alexander continued for some time in a very dangerous condition. However, he at last recovered his strength, and showed himself again to his army, which filled them with the greatest joy.

On the king's return to Pattala, he resolved to sail down

Sangala
taken and
razed.

The troops
refuse to
proceed
further.

At last Alexander
consents to
return.
Voyage
down the
Indus,
B.C. 325.

Macedonia. the other branch of the Indus, that he might see whether it was more safe and commodious for his fleet than that which he had already tried ; and for this he had very good reasons. He had resolved to send Nearchus with his fleet by sea, through the Persian Gulf, up the River Tigris, to meet him and his army in Mesopotamia ; but as the possibility of this voyage depended on the ceasing of the etesian winds, there was a necessity for laying up the fleet till the season should prove favourable. Alexander, therefore, sailing through this branch of the Indus, sought on the sea-coast for bays and creeks, where his fleet might anchor in safety ; he also caused pits to be sunk, which might be filled with fresh water for the use of his people, and took all imaginable precautions for preserving them in ease and safety till the season would allow them to continue their voyage. In this he succeeded to his wish ; for he found this branch of the river Indus, at its mouth, spread over the plain country, and forming a kind of lake, in which a fleet might ride with safety. He therefore appointed Leonatus, and a part of his army, to carry on such works as were necessary, causing them to be relieved by fresh troops as often as there was occasion ; then having given his last instructions to Nearchus, he departed with the rest of the army, in order to march back to Babylon.

His march through Gedrosia.

Before the king's departure, many of his friends advised him against the route which he intended to take. They told him that nothing could be more rash or dangerous than this resolution. They informed him, that the country through which he was to travel was a wild uncultivated desert ; that Semiramis, when she led her soldiers this way out of India, brought home but twenty of them ; and that Cyrus attempting to do the same, returned with only seven. But all this was so far from deterring Alexander, that it more than ever determined him to pursue no other route. As soon, therefore, as he had put things in order, he marched at the head of a sufficient body of troops to reduce the Oritæ, who had never vouchsafed either to make their submission or to court his friendship. Their territories lay upon the other side of a river called Arabis, which Alexander crossed so speedily, that they had no intelligence of his march ; whereupon most of them quitted their country, and fled into the deserts. Their capital he found so well situate, that he resolved to take it out of their hands, and to cause a new and noble city to be founded there, the care of which he committed to Hephæstion. Then he received the deputies of the Oritæ and Gedrosi ; and having assured them that if the people returned to their villages, they should be kindly treated, and having appointed Apollophenes president of the Oritæ, and left a considerable body of troops under Leonatus to secure their obedience, he began his march through Gedrosia. In this march his troops suffered incredible hardships. The road was very uncertain and troublesome, on account of its lying through deep and loose sands, rising in many places into hillocks, which forced the soldiers to climb, at the same time that it sunk under their feet ; there were no towns, villages, nor places of refreshment, to be met with ; so that, after excessive marches, they were forced to encamp among these dry sands. As to provisions, they hardly met with any during their whole march. The soldiers were therefore obliged to kill their beasts of carriage ; and such as were sent to bring some corn from the sea-side, were so grievously distressed, that, though it was sealed with the king's signet, they cut open the bags, choosing rather to die a violent death for disobedience than perish by hunger. When the king, however, was informed of this, he freely pardoned the offenders ; he was also forced to accept the excuses that were daily made for the loss of mules, horses, &c., which were in truth eaten by the soldiers, and their carriages broken in pieces to avoid further trouble. As for water, their want of it was a great misfortune, and yet their finding it in plenty was sometimes a greater ; for,

as in the one case they perished with thirst, so in the other Macedonia they were thrown into dropsies, and rendered incapable of travel. Frequently they met with no water for the whole day together ; sometimes they were disappointed of it at night, in which case, if they were able, they marched on ; so that it was common with them to travel 30, 40, 50, or even 60 miles without encamping. Through these hardships numbers were obliged to fall into the rear ; and of these many were left behind, and perished ; for indeed scarcely any of them ever joined the army again. Their miseries, however, they sustained with incredible patience, being encouraged by the example of their king, who, on this occasion, suffered greater hardships than the meanest soldier in his army.

At last they arrived at the capital of Gedrosia, where they refreshed themselves, and staid some time ; after which they marched into Caramania, which being a very plentiful country, made them ample amends for the hardships and fatigues which they had sustained. Here they were joined, first by Craterus with the troops under his command, along with a number of elephants ; then came Stasanor, president of the Arians, and Pharismenes, the son of Phrataphernes, the governor of Parthia. They brought with them camels, horses, and other beasts of burden, in vast numbers ; having foreseen that the king's march through Gedrosia would be attended with the loss of the greater part, if not all, of the cavalry and beasts belonging to his army. During Alexander's stay in Caramania, he redressed the injuries of his people, who had been grievously oppressed by their governors during his absence. Here also he was joined by his admiral, Nearchus, who brought with him an account that all under his command were in perfect safety and in excellent condition ; intelligence with which the king was mightily pleased, and, after having bestowed on him singular marks of his favour, sent him back to the navy. Alexander next set out for Persia, where great disorders had been committed during his absence. These he also redressed, and caused the governor to be crucified ; appointing in his room Peucestas, who had saved his life when he fought singly against a whole garrison, as above related. The new governor was no sooner invested with his dignity than he laid aside the Macedonian garb, and put on that of the Medes, being the only one of Alexander's captains who, by complying with the manners of the people he governed, gained their affection.

Whilst Alexander visited the different parts of Persia, he took a view, amongst the rest, of the ruins of Persepolis, where he is said to have expressed great sorrow for the destruction he had formerly occasioned. From Persepolis, he marched to Susa, where he gave an extraordinary loose to pleasure, resolving to make himself and his followers some amends for the difficulties which they had hitherto undergone, purposing at the same time so effectually to unite his newly-conquered with his hereditary subjects, that the jealousies and fears which had hitherto tormented both should no longer subsist. With this view he married two wives of the blood-royal of Persia—Barsine or Statira, the daughter of Darius, and Parysatis, the daughter of Ochus. Drypetis, another daughter of Darius, he gave to Hephæstion ; Amastrine, the daughter of Oxyartes, the brother of Darius, married Craterus ; and to the rest of his friends, to the number of eighty, he gave other women of the highest quality. All these marriages were celebrated at once, Alexander himself bestowing fortunes upon them. He likewise directed that an account should be taken of the number of his officers and soldiers who had married Asiatic wives ; and though they appeared to be ten thousand, yet he gratified each of them according to his rank. He next resolved to pay the debts of his army, and thereupon issued an edict directing every man to register his name, and the sum he owed ; an order with which the soldiers complying

His proceedings in Persia.

Macedonia. slowly, from an apprehension that there was some design against them, Alexander ordered tables heaped with money to be set in all quarters of the camp, and caused every man's debts to be paid on his bare word, without even making any entry of his name, though the whole sum amounted to twenty thousand talents. On such as had distinguished themselves in an extraordinary manner he bestowed crowns of gold. Peucestas received the first, Leonatus the second, Nearchus the third, Onesicritus the fourth, Hephæstion the fifth, and the rest of his guards had each of them one. After this he made other dispositions for conciliating, as he supposed, the differences amongst his subjects. He reviewed the thirty thousand youths whom at his departure for India he had ordered to be taught Greek and the Macedonian discipline, expressing high satisfaction at the fine appearance they made, which rendered them worthy of the appellation he bestowed on them, that of *Epigoni*, or successors. He promoted also, without any distinction of nation, all those who had served him faithfully and valiantly in the Indian war. When all these regulations were made, he gave the command of his heavy-armed troops to Hephæstion, and ordered him to march directly to the banks of the Tigris; whilst in the meantime a fleet was equipped for carrying the king and the troops which he retained with him down to the ocean.

Death of Alexander. B.C. 323. Thus ended the exploits of Alexander, the greatest conqueror that ever the world saw, at least with respect to the rapidity of his conquests. In the course of twelve years he had brought under his subjection Egypt, Libya, Asia Minor, Syria, Phœnicia, Palestine, Babylonia, Persia, with part of India and Tartary. Still, however, he meditated greater things. He had now got a great taste for maritime affairs, and is said to have meditated a voyage to the coasts of Arabia and Ethiopia, and thence round the whole continent of Africa to the Straits of Gibraltar. But of this there is no great certainty, though that he intended to subdue the Carthaginians and Italians is more than probable. All these designs, however, were frustrated by his death, which happened at Babylon in the year 323 B.C. He is said to have received several warnings of his approaching fate, and to have been advised to avoid that city, which advice he either despised or could not follow. He died of a fever, after eight days' illness, without naming any successor; having only given his ring to Perdiccas, and left the kingdom, as he said, "to the strongest."

The character of this great prince has been variously represented; but most historians seem to have looked upon him rather as an illustrious madman than one upon whom the epithet of Great could be properly bestowed. From a careful observation of his conduct, however, it must appear that he possessed not only a capacity to plan, but likewise to execute, the greatest enterprises which ever entered into the mind of any of the human race. From whatever cause the notion originated, it is plain that he imagined himself a divine person, and born to subdue the whole world; and extravagant and impracticable as this scheme may appear at present, it cannot at all be looked upon in the same light in the age of Alexander. The Greeks were in his time the most powerful people in the world in respect to their skill in the military art, and the Persians were the most powerful with respect to wealth and numbers. The only other powerful nations in the world were the Carthaginians, Gauls, and Italian nations. From a long series of wars which the Carthaginians carried on in Sicily, it appeared that they were by no means capable of contending with the Greeks, even when they had an immense superiority of numbers; and much less could they have sustained an attack from the whole power of Greece and Asia united. The Gauls and Italians were indeed very brave, and of a martial disposition; but they were barbarous, and could not have resisted armies well-disciplined, and under the command of such a skilful leader as Alexander. Even long

after this time, it appeared that the Romans themselves could Macedonia. not have resisted the Greeks, since Regulus, after having defeated the Carthaginians, and reduced them to the utmost distress, was totally unable to resist a Carthaginian army commanded by a Greek general, and trained to Greek discipline.

Thus it appears that the scheme of Alexander cannot by any means be accounted that of a madman, or of one who projects great things without judgment, and the means necessary to execute them. If from his actions we consider the end which he most probably had in view could his scheme have been accomplished, we shall find it not only the greatest, but the best, which can possibly be imagined. He did not conquer to destroy, enslave, or oppress, but to civilize and to unite the whole world as one nation. No sooner was a province conquered than he took care of it as if it had been part of his paternal inheritance. He allowed not his soldiers to oppress and plunder the Persians, which they were very much inclined to do; on the contrary, by giving in to the oriental customs himself, he strove to extinguish that inveterate hatred which had so long subsisted between the two nations. In the Scythian countries which he subdued he pursued the same excellent plan. His courage and military skill, in which he never was excelled, were displayed, not with a view to rapine or desultory conquest, but to civilize and induce the barbarous inhabitants to employ themselves in a more proper way of life. Amidst the hardships of a military life, obstinate sieges, bloody battles, and dear-bought victories, he still respected the rights of mankind, and practised the mild virtues of humanity. The conquered nations enjoyed their ancient laws and privileges; the rigours of despotism were softened; arts and industry encouraged; and the proudest Macedonian governors compelled, by the authority and example of Alexander, to observe the rules of justice towards their meanest subjects. To bridle the fierce inhabitants of the Scythian plains, he founded cities and established colonies on the banks of the Iaxartes and Oxus; and those destructive campaigns usually ascribed to his restless activity and blind ambition appeared to the discernment of this extraordinary man, not only essential to the security of the conquests which he had already made, but necessary for the more remote and splendid expeditions which he still purposed to undertake, and which he performed with singular boldness and unexampled success.

He was of a low stature, and somewhat deformed; but the activity and elevation of his mind animated and ennobled his frame. By a life of continual labour, and by an early and habitual practice of the gymnastic exercises, he had hardened his body against the impressions of cold and heat, hunger and thirst, and prepared his robust constitution for bearing such exertions of strength and activity as have appeared incredible to the undisciplined softness of modern times. In generosity and in prowess he rivalled the greatest heroes of antiquity; and in the race of glory, having finally outstripped all competitors, became ambitious to surpass himself. His superior skill in war gave uninterrupted success to his arms; and his natural humanity, enlightened by the philosophy of Greece, taught him to improve his conquests to the best interests of mankind. In his extensive dominions he built or founded not less than seventy cities; the situation of which, being chosen with consummate wisdom, tended to facilitate communication, to promote commerce, and to diffuse civilization through the greatest nations of the earth. It may be suspected, indeed, that he mistook the extent of human power, when in the course of one reign he undertook to change the face of the world; and that he miscalculated the stubbornness of ignorance and the force of habit, when he attempted to enlighten barbarism, to soften servitude, and to transplant the improvements of Greece into an African and Asiatic soil, where they have never been known to flourish. Yet

Macedonia. let not the designs of Alexander be too hastily accused of extravagance. Whoever seriously considers what he actually performed before his thirty-third year, will be cautious of determining what he might have accomplished had he reached the ordinary term of human life. His resources were peculiar to himself; and such views as well as actions became him, as would have become none besides. In the language of a distinguished historian, "he seems to have been given to the world by a peculiar dispensation of Providence, being a man like to none other of the human kind."

Causes of the dissolution of his empire.

With the death of Alexander fell also the glory of the Macedonians, who very soon relapsed into a situation as bad as, or perhaps worse than, that in which they had been before the reign of Philip. This was occasioned principally by his not having distinctly named a successor, and having no child of his own come to the years of discretion to whom the kingdom might seem naturally to belong. The ambition and jealousy of his mother Olympias, of his queen Roxana, and especially of the great commanders of his army, not only prevented a successor from being ever named, but occasioned the death of every person, whether male or female, who was in the least related to Alexander. To have a just notion of the origin of these disturbances, it is necessary, in the first place, to understand the state of Macedonian affairs at the time of Alexander's death.

When Alexander set out for Asia, he left Antipater in Macedonia, to prevent any disturbances that might arise either there or in Greece. The Greeks, even during the lifetime of Alexander, bore the superiority which he exercised over them with great impatience; and, though nothing could be more gentle than the government of Antipater, yet he was exceedingly hated, because he obliged them to be quiet. One of the last actions of Alexander's life set all Greece in a flame. He had, by an edict, directed all the cities of Greece to recall their exiles; which edict, when it was published at the Olympic games, created much confusion. Many of the cities were afraid that when the exiles returned they would change the government; most of them doubted their own safety if the edict took effect; and all of them held this peremptory decree to be a total abolition of their liberty. No sooner, therefore, did the news of Alexander's death arrive than they prepared for war.

In Asia the state of things was not much better; not indeed through any inclination of the conquered countries to revolt, but through the dissensions amongst the commanders. In the general council which was called soon after the death of Alexander, it was at last agreed, or rather commanded by the soldiers, after much confusion and altercation, that Aridaeus, the brother of Alexander, who had always accompanied the king, and had been wont to sacrifice with him, should assume the sovereignty. This Aridaeus was a man of slender parts and judgment, not naturally, but by the wicked practices of Olympias, who had given him poisonous draughts in his infancy, lest he should stand in the way of her son Alexander, or any of his family; and for this, or some other reason, Perdiccas, Ptolemy, and most of the cavalry officers, resented his promotion to such a degree that they quitted the assembly, and even the city. However, Meleager, at the head of the phalanx, vigorously supported their first resolution, and threatened loudly to shed the blood of those who affected to rule over their equals, and to assume a kingdom which nowise belonged to them. Aridaeus was accordingly arrayed in royal robes, had the arms of Alexander put upon him, and was saluted by the name of Philip, to render him more popular. Thus were two parties formed, at the head of which were Meleager and Perdiccas, both of them pretending vast concern for the public good, yet at bottom desiring nothing more than their own advantage. Perdiccas was a man of high birth, and had a supreme com-

mand in the army, was much in favour with Alexander, and one in whom the nobility had placed great confidence. Meleager had become formidable by the phalanx being on his side, and having the nominal king entirely in his power; for Aridaeus, or Philip, was obliged to comply with whatever he thought proper, and publicly declared that whatever he did was by the advice of Meleager; so that he made his minister accountable for his own schemes, and nowise endangered himself. The Macedonians also, besides their regard for the deceased king, soon began to entertain a personal love for Philip on account of his moderation.

It is remarkable, however, that notwithstanding all the favours which Alexander had conferred upon his officers, and the fidelity with which they had served him during his life, only two of them were attached to the interests of his family after his death. These were Antipater and Eumenes the Cardian, whom he had appointed his secretary. Antipater, as we have already seen, was embroiled with the Greeks, and could not assist the royal family, who were in Asia; and Eumenes had not as yet sufficient interest to form a party in their favour. In a short time, however, Perdiccas prevailed against Meleager, and caused him to be murdered; by which means the supreme power for a time fell into his hands. His first step, in consequence of this power, was to distribute the provinces of the empire amongst the commanders, in order at once to prevent competitors, and to satisfy the ambition of the principal leaders of the army. Aridaeus, and the son of Roxana, born after the death of his father, were to enjoy the regal authority. Antipater had the government of the European provinces. Craterus received the title of Protector. Perdiccas was made general of the household troops, in the room of Hephaestion. Ptolemy, the son of Lagus, obtained Egypt, Libya, and that part of Arabia which borders upon Egypt. Cleomenes, a man of infamous character, whom Alexander had appointed receiver-general in Egypt, was made Ptolemy's deputy. Leomedon had Syria; Philotas, Cilicia; Python, Media; Eumenes, Cappadocia, Paphlagonia, and all the country bordering on the Euxine Sea, as far as Trapezus; but these were not yet conquered, so that he was a governor without a province. Antigonus received Pamphylia, Lycia, and Phrygia Major; Cassander, Caria; Menander, Lydia; Leonatus, Phrygia, on the Hellespont.

In the meantime, not only Alexander's will, but even his remains, were so much neglected, that his body was allowed to lie seven days before any notice was taken of it, or any orders were given for its being embalmed. The only will he left was a short memorandum of six things which he wished to have done. 1. A fleet of one thousand stout galleys was to be built and employed against the Carthaginians and other nations who might oppose the reduction of the sea-coasts of Africa and Spain, with all the adjacent islands as far as Sicily. 2. A large and regular highway was to be constructed along the coast of Africa, as far as Ceuta and Tangier. 3. Six temples of extraordinary magnificence were to be erected, at the expense of one thousand five hundred talents each. 4. Castles, arsenals, havens, and yards for building ships, were to be established in proper places throughout his empire. 5. Several new cities were to be built in Europe and Asia; those in Asia to be inhabited by colonies from Europe, and those in Europe to be filled with Asiatics; that by blending the people and the manners of both, the hereditary antipathy which had hitherto subsisted between the inhabitants of these two continents might, if possible, be eradicated. Lastly, he had projected the building of a pyramid, equal in size and beauty to the largest in Egypt, in honour of his father Philip. But all these designs were, on the pretence of their being expensive, referred to a council of Macedonians, to be held nobody knew when or where.

The government, being now in the hands of Perdiccas

Meleager murdered, and the empire divided.

Alexander's body neglected, and his will set aside.

Macedonia. and Roxana, soon became cruel and distasteful. Alexander was scarcely dead when the queen sent for Statira and Drypetis, the two daughters of Darius, one of whom had been married to Alexander, and the other to Hephæstion; and as soon as they arrived at Babylon, she caused them both to be murdered, that no son of Alexander by any other woman, or of Hephæstion, might give any trouble to her or her son Alexander. Sisygambis, the mother of Darius, no sooner heard that Alexander the Great was dead, than she laid violent hands on herself, being apprehensive of the calamities which were about to ensue.

Revolt of the Greeks. B.C. 321. War was first declared in Greece against Antipater in the year 321 B.C.; and, through the treachery of the Thes-salians, that general was defeated, with the army he had under his own command. Leonatus was therefore sent from Asia, with a very considerable army, to his assistance; but both were overthrown with great loss by the confederates, and Leonatus himself was killed. In a short time, however, Craterus arrived in Greece with a great army, the command of which he resigned to Antipater. The army of the confederates amounted to about twenty-five thousand foot and three thousand horse; but Antipater commanded no fewer than forty thousand foot, three thousand archers, and five thousand horse. In such an unequal contest, therefore, the Greeks were defeated, and forced to sue for peace, which they did not obtain except on condition of their receiving Macedonian garrisons into several of their cities. At Athens also the democratic government was abrogated; and such a dreadful punishment did this seem to the Athenians, that twenty-two thousand of them left their country and retired into Macedonia.

Disturbances in Asia and Thrace. Whilst these things were doing in Greece, disturbances began also to arise in Asia, and in Thrace. The Greek mercenaries, who were dispersed throughout the inland provinces of Asia, despairing of ever being allowed to return home by fair means, determined to attempt it by force. For this purpose they assembled to the number of twenty thousand foot and three thousand horse; but they were all cut off to a man by the Macedonians. In Thrace, Lysimachus was attacked by one Seuthes, a prince of that country, who claimed the dominions of his ancestors, and had raised an army of twenty thousand foot and two thousand horse. But though the Macedonian commander was forced to engage this army with no more than four thousand foot and two thousand horse, yet he kept the field of battle, and could not be driven out of the country.

Ambition and cruelty of Perdiccas. Perdiccas, in the meantime, by pretending friendship to the royal family, had gained over Eumenes entirely to his interest; and at last put him in possession of the province of Cappadocia by the defeat of Ariarathes, king of that country, whom he afterwards caused to be crucified. His ambition, however, now began to involve him in difficulties. At the first division of the provinces, Perdiccas, to strengthen his own authority, had proposed to marry Nicæa, the daughter of Antipater; and so well was this proposal relished, that her brethren, Jollas and Archias, conducted her to him, in order to be present at the celebration of the nuptials. But Perdiccas had now other objects in view. He had been solicited by Olympias to marry her daughter Cleopatra, the widow of Alexander King of Epirus, and who then resided at Sardis, in Lydia. Eumenes promoted this match to the utmost of his power, because he thought it would be for the interest of the royal family; and his persuasions had such an effect on Perdiccas, that he was sent to Sardis to compliment Cleopatra, and to carry presents to her in name of her new lover. In the absence of Eumenes, however, Alcetas, the brother of Perdiccas, persuaded him to marry Nicæa; but in order to gratify his ambition, he resolved to divorce her immediately after the marriage, and to marry Cleopatra. By this last alliance he hoped to have a pretence for altering the

government of Macedonia; and, as a necessary measure preparative to these, he entered into contrivances for destroying Antigonus. Unfortunately for himself, however, he ruined all his schemes by his own jealousy and precipitate cruelty. Cynane, the daughter of Philip by his second wife, had brought her daughter Adda, who was afterwards named Eurydice, to court, in hopes that King Aridæus might marry her. Against Cynane, Perdiccas, from some political motives, conceived such a grudge, that he caused her to be murdered. This raised a commotion in the army, which frightened Perdiccas to such a degree that he now promoted the match between Aridæus and Eurydice, to prevent which he had murdered the mother of the young princess. But, in the meantime, Antigonus, knowing the designs of Perdiccas against himself, fled with his son Demetrius to Greece, there to take shelter under the protection of Antipater and Craterus, whom he informed of the ambition and cruelty of the regent.

A civil war was now kindled up. Antipater, Craterus, Neoptolemus, and Antigonus, were combined against Perdiccas; and it was the misfortune of the empire in general that Eumenes, the most able general, as well as the most virtuous of all the commanders, was on the side of Perdiccas, because he believed him to be in the interest of Alexander's family. Ptolemy in the meantime remained in quiet possession of Egypt, but without the least intention of owning any person as his superior. However, he also acceded to the league formed against Perdiccas, and thus the only person in the whole empire who consulted the interest of the royal family was Eumenes.

It was now thought proper to bury the body of Alexander, which had been kept for two years, during all which time preparations had been making for its interment. Aridæus, to whose care it was committed, set out from Babylon for Damascus, in order to carry the king's body to Egypt. This was much against the will of Perdiccas; for it seems there was a superstitious report, that wherever the body of Alexander was laid, that country should flourish most. Perdiccas, therefore, out of regard to his native soil, would have it conveyed to the royal sepulchres in Macedonia; but Aridæus, pleading the late king's express direction, was determined to carry it into Egypt, from thence to be conveyed to the temple of Jupiter Ammon. The funeral was accordingly conducted with all imaginable magnificence. Ptolemy came to meet the body as far as Syria; but, instead of burying it in the temple of Jupiter Ammon, he erected a stately temple for it in the city of Alexandria; and, by the respect which he showed for his dead master, induced many of the Macedonian veterans to join him, who were afterwards of the greatest service.

No sooner was the funeral over, than the parties above mentioned came to blows. Perdiccas marched against Ptolemy, but was slain by his own men, who, after the death of their general, submitted to his antagonist; and thus Eumenes was left alone to contend against all the other generals who had served under Alexander. In this contest, however, he would by no means have been over-matched, had his soldiers been attached to him; but as they had been accustomed to serve against those very generals against whom they were now to fight, they were upon all occasions ready to betray and desert Eumenes. However, he defeated and killed Neoptolemus and Craterus; but then found himself obliged to contend with Antipater and Antigonus. Antipater was now appointed protector of the kings, with sovereign power; and Eumenes was about the same time declared a public enemy. A new division of Alexander's empire took place. Egypt, Libya, and the parts adjacent, were given to Ptolemy, because they could not be taken from him. Syria was confirmed to Leomedon. Philoxenus received Cilicia. Mesopotamia and Arbelitus were given to Amphimachus. Babylon was bestowed on

Macedonia. Seleucus. Susiana fell to Antigenes, who commanded the Macedonian *Argyraspidæ*, or Silver Shields, because he was the first who opposed Perdikkas. Peucestas held Persia; Tlepolemus had Caramania; Python had Media as far as the Caspian Straits; Stasander had Aria and Drangia; Philip, Parthia; Stasenor, Bactria and Sogdia; Sibirtius, Aracopa; Oxyartes, the father of Roxana, Paropanisus. Another Python had the country between this province and India. Porus and Taxiles retained what Alexander had given them, refusing to part with any portion of their dominions. Cappadocia was assigned to Nicanor. Phrygia Major, Lycaonia, Pamphylia, and Lycia, were given to Antigonos; Caria to Cassander; Lydia to Clytus; and Phrygia the Less to Arideus. Cassander was appointed general of the horse; whilst the command of the household troops was given to Antigonos, with orders to prosecute the war against Eumenes. Antipater having thus settled everything as well as he could, returned to Macedonia with the two kings, to the great joy of his countrymen, having left his son Cassander as a check upon Antigonos in Asia.

Total destruction of Alexander's family.

Matters now seemed to wear a better aspect than they had yet done; and, if Eumenes had believed that his enemies really consulted the interest of Alexander's family, there is not the least doubt that the war would have been immediately terminated. He saw, however, that the design of Antigonos was altogether a selfish one, and consequently he refused to submit. From this time, therefore, the Macedonian empire in Asia ceased to exist; and the Macedonian affairs were now entirely confined to that kingdom itself, and to Greece. Antipater had not been long in Macedonia after his return, when he died; and the last act of his life completed the ruin of Alexander's family. With a view to the public good, he had appointed Polysperchon, one of the eldest of Alexander's captains, to be protector and governor of Macedonia. This failed not to disgust his son Cassander, who thought he had a natural right to these offices, and of course kindled up a new civil war in Macedonia. This was indeed highly promoted by his first actions as a governor. He began with attempting to remove all the governors appointed in Greece by Antipater, and to restore democracy wherever it had been abolished. The immediate consequence of this was, that the people refused to obey their magistrates; the governors refused to resign their places, and applied for assistance to Cassander. Polysperchon had also the imprudence to recal Olympias from Epirus, and to allow her a share in the administration, which Antipater, and even Alexander himself, had always refused her. The consequence of all this was, that Cassander invaded Greece, where he prevailed against Polysperchon. Olympias returned to Macedonia, where she cruelly murdered Arideus and his wife Eurydice. But she was herself put to death by Cassander, who afterwards caused Roxana and her son to be murdered; and Polysperchon being driven into Etolia, first raised to the crown Hercules, the son of Alexander by the daughter of Darius, and then, by the instigation of Cassander, murdered him, by which means the line of Alexander the Great became totally extinct.

Various revolutions in the government.

Cassander having thus destroyed all the royal family, assumed the regal title, as he had for sixteen years before had all the power. But he enjoyed the title of King of Macedonia only three years, after which he died, about 298 B.C. By Thessalonica, the daughter of Philip, King of Macedonia, he left three sons—Philip, Antipater, and Alexander. Philip succeeded him, but soon afterwards died of a consumption, and a contest immediately began between the two brothers, Antipater and Alexander. Antipater seized the kingdom, and, to secure himself in it, murdered his mother Thessalonica. Alexander invited Pyrrhus, King of Epirus, and Demetrius, the son of Antigonos, to assist him, and revenge the death of his mother. But Pyrrhus being bought off, and a peace concluded between the

Macedonia. brothers, Alexander, afraid of having too many protectors, formed a scheme of getting Demetrius assassinated. Instead of this, however, both he and Antipater were put to death; and Demetrius became King of Macedonia, four years after the death of Cassander.

In 287 before Christ, Demetrius was driven out by Pyrrhus, who was again driven out two years after by Lysimachus, who was soon afterwards killed by Seleucus Nicanor; and Seleucus in his turn was murdered by Ptolemy Caranus, who became King of Macedonia about 280 before our era. The new king was in a short time cut off, with his whole army, by the Gauls; and Antigonos Gonatus, the son of Demetrius Poliorcetes, became King of Macedonia in 278 B.C. He proved successful against the Gauls, but was driven out by Pyrrhus, King of Epirus, who, however, soon disoblged his subjects to such a degree that Antigonos recovered a great part of his kingdom. But in a little time, Pyrrhus being killed at the siege of Argos in Greece, Antigonos was restored to the whole of Macedonia; but scarcely was he seated on the throne, when he was driven from it by Alexander the son of Pyrrhus. The new invader was in his turn expelled by Demetrius the son of Antigonos, who, though at that time but a boy, had almost made himself master of Epirus. In this enterprise, however, he was disappointed; but by his means Antigonos was restored to his kingdom, which he governed for many years in peace. By a stratagem he made himself master of the city of Corinth, and from that time began to form schemes for the thorough conquest of Greece. The method he took to accomplish this was, to support the petty tyrants of Greece against the free states, which indeed weakened the power of the latter, but involved the whole country in so many calamities, that these transactions redounded but little to the reputation either of his arms or of his honour. He died about the year 243, leaving the kingdom to his son Demetrius II.

Neither Demetrius nor his successor, Antigonos Doson, performed anything remarkable. In 221 B.C., the kingdom fell to Philip, the last but one of the Macedonian monarchs. To him Hannibal, after the battle of Cannæ, applied for assistance, which he refused; and the same imprudence which made him refuse this assistance prompted him to embroil himself with the Romans, and at last to conclude a treaty with them, by which he in effect became their subject, being tied up from making peace or war except according to their pleasure. In 179 B.C. he was succeeded by his eldest son Perseus, under whom the war with the Romans was renewed. Even yet the Macedonians were terrible in war; and their phalanx, when properly conducted, seems to have been absolutely invincible by any method of making war at that time known. The Romans had never encountered such a terrible enemy; and in the first battle, which happened 171 B.C., they were defeated with the loss of 2200 men, whilst the Macedonians lost no more than 60. The generals of Perseus now pressed him to storm the enemy's camp; but he being naturally of a cowardly disposition, refused to comply, and thus the best opportunity he ever had was lost. Still, however, the Romans gained little or no advantage over it, until the year 168 B.C., when Paulus Æmilius, a most experienced commander, was sent to Macedonia. Perseus now put everything upon the issue of a general engagement; and Æmilius, with all his courage and military experience, would have been defeated, had the Macedonians been commanded by a general of the smallest courage or conduct. The light-armed Macedonians charged with such vigour, that, after the battle, some of their bodies were found within two furlongs of the Roman camp. When the phalanx came to charge, the points of their spears striking into the Roman shields, kept the heavy-armed troops from making any mo-

War with the Romans, B.C. 221.

nius
||
Macer.

tion; whilst, on the other hand, Perseus's light-armed men did terrible execution. On this occasion, it is said that Æmilius tore his clothes, and gave up all hopes. However, the Roman general, perceiving that as the phalanx gained ground it lost its order in several places, caused his own light-armed troops to charge in those places, whereby the Macedonians were soon thrown into confusion. Perseus with his horse took to flight, and the infantry at last did the same, but not till 20,000 of them had lost their lives.

This battle decided the fate of Macedonia, which immediately submitted to the conqueror. The cowardly king took refuge in the island of Samothrace, but was at last obliged to surrender to the Roman consul, by whom he was carried to Rome, led in triumph, and afterwards most barbarously treated. Some pretenders to the throne afterwards appeared; but being unable to defend themselves against the Romans, the country was reduced to a Roman province in the year 148 B.C.

MACEDONIUS, the name of two bishops of Constantinople.

(1.) *Macedonius*, a deacon, raised to the bishopric by the Arians in A.D. 341, while the orthodox party elected the patriarch Paul. The partisans of the two rivals involved the city in a tumultuous broil, murdered Hermogenes the general whom Constantius II., during his own absence, had empowered to preserve order, and were not quelled until the emperor himself returned to the city and banished Paul. Macedonius was recognised as patriarch in A.D. 342. In that year Paul again returned, and was again banished, and Macedonius, amid much tumult and bloodshed, was forcibly installed in the see by the imperial troops. Compelled, however, by the intervention of Constans in 348 to confine his authority again to one church, and to resign the patriarchate to his former opponent, he was reinstalled in A.D. 350. He then took vengeance on his opponents by a general persecution, expelling them from all the churches in the patriarchate, banishing many, and torturing others to death. Scarcely less disastrous and bloody was the tumult that he excited among the citizens by removing the ashes of Constantine the Great from the dilapidated church of the Apostles to the church of St Acacius. In A.D. 359, on the division of the Arians into Acacians, or pure Arians, and semi-Arians, Macedonius adhered to the latter, and consequently became obnoxious to the former. His enemies, thus increased, effected his expulsion from the see in the following year at the council of Constantinople. This event, it is said, he survived only a short time.

After his deposition, Macedonius became a bold advocate of the doctrines of the semi-Arians. From this circumstance, that sect in the course of time were called *Macedonians*. Their peculiar tenet was, that the Holy Ghost is distinct from the Father and Son, and is nothing else than a divine influence pervading the entire universe. From this impugning of the Spirit, they were sometimes named *Pneumachi*. They were also called *Marathonians*, from Marathonius, one of their leaders.

(2.) *Macedonius* nominated bishop of Constantinople by Anastasius I., about A.D. 496. His subscription of the Henoticon of Zeno induced the monks of the city to renounce his communion, and to resist obstinately his attempts to reconcile them. Yet, with a mild tolerance that marked the general tenor of his conduct, he refrained from using harsh measures against them. About 511 the Emperor Anastasius withdrawing his favours from Macedonius on account of his recognition of the council of Chalcedon, deposed and banished him on a charge of heresy and other crimes. This sentence, which was condemned by the church in all parts of the empire, Vitalian the Goth, in 514, attempted by his unsuccessful rebellion to repeal. Macedonius died in exile in A.D. 516.

MACER, CAIUS LICINIUS, a Roman historian, and father

of the orator Caius Licinius Calvus, was probably born about 110 B.C. After holding the quæstorship, he was elected a tribune of the people in 73 B.C., and subsequently became prætor and governor of a province. In 66 B.C. he was arraigned by Cicero under the law *De Repetundis*, and dreading lest the verdict should be damnatory, and should involve his family in loss and disgrace, he put an end to his existence. The merits of Macer as an author can scarcely be determined by the few stray quotations from his *Annales* found in ancient authors; but he is supposed by Niebuhr to have displayed accurate and extensive research, and to have supplied abundant materials both to Livy and Dionysius.

MACERATA, a city of central Italy, capital of a cognominal delegation of the Papal States, is situate on an eminence between the rivers Potenza and Chienti, 21 miles S.W. of Ancona, and 170 from Rome. It is well built, with generally straight, spacious, and clean streets, and is surrounded by walls having six gates. In the centre of the town is a large but irregular square, in which are some of the principal buildings, including the cathedral, the palace of the delegate, and the theatre. Macerata is the see of a bishop, and the seat of a court of appeal for several of the neighbouring delegations. It has a number of churches and convents, and a university for philosophy, theology, and medicine, with a library of 20,000 volumes. It carries on some trade in corn, silk, and cattle. Under the French it was the capital of the department of Musone. Pop. 16,000. The delegation of Macerata is for the most part mountainous and wooded; but the valleys and plains are fertile and well cultivated, producing abundance of corn, wine, and fruits in great variety. Many cattle are reared. Area 861 square miles. Pop. (1850) 239,942.

MAGILLICUDDY REEKS. See KERRY.

MAGILLIVRAY, DR WILLIAM, an eminent naturalist, was born at Old Aberdeen in 1796. Amid great poverty, he was enabled to enter King's College, in his native town, and after taking the degree of A.M., he studied medicine, first at Aberdeen and afterwards at Edinburgh. His native bias, however, for natural history made him forego all intention of adopting the medical profession, and accordingly he never graduated as M.D. In 1823 he was appointed assistant to the regius professor of natural history, and regius keeper of the museum of the Edinburgh University. This appointment he resigned in 1831 for the office of conservator of the museum of the Royal College of Surgeons in Edinburgh. This work, together with translating, editing, delivering lectures, and contributing to scientific journals, was congenial to Macgillivray, since it introduced him to many naturalists, and afforded a continual facility for his favourite studies. In 1841 his scholarship, unsupported by any external influence, raised him to the chair of natural history in Marischal College, Aberdeen. There his excellence as a teacher, and his gentle and unassuming conduct, soon rendered him popular. During the whole of his life, his body, not less than his mind, had been active in the pursuit of knowledge; and it was while exploring the central region of the Grampians, in 1850, that he caught the disorder that ultimately proved fatal. After a lingering illness, during which he never ceased to work, he died in September 1852. The most popular of Dr Macgillivray's numerous works are the following:—*A History of British Birds*, in 5 vols. 8vo, 1837-1852; *A Manual of British Ornithology*, in 2 vols. 12mo, 1840-1841, reprinted in 1846; *The Flowering Plants and Ferns of Great Britain and Ireland*, 8vo, eighth edition, 1852; and a posthumous work, *The Natural History of Deeside and Bruemar*, 1856, the copyright of which was bought by Prince Albert. He also contributed largely to the *Transactions of the Wernerian Natural History Society*, to the *Edinburgh Philosophical Journal*, to the *Edin-*

Machiavelli.

MACHIAVELLI, NICOLÒ, for many years secretary of the republic of Florence, and justly celebrated for his political, historical, and other writings, was born at Florence on the 3d of May 1469, being descended from a family which traced its origin up to the ancient marquises of Tuscany, particularly to the Marquis Hugo, who lived about the middle of the ninth century. The Machiavellis were signors or lords of Monte-Spertoli; but preferring the right of citizenship in Florence to the useless conservation of privileges which were daily becoming more and more obnoxious to the rising commonwealth, they prudently submitted to its laws in order to accept employment in the highest offices of the magistracy. This family was one of those attached to the Guelfic party which abandoned Florence in the year 1260, after the defeat at Monte-Aperti. But their secession was merely temporary. Having returned to their native country, they regained their influence, and occupied some of the first offices of the state; no less than thirteen of their number having held the situation of gonfaloniere of justice, and fifty-three that of prior, dignities which were then considered as the most important in the republic. The father of Machiavelli was a jurisconsult, and lived in a state but little removed from poverty. His mother, who appears to have been a woman of talent, loved poetry, and composed verses with facility. It is believed that, about the year 1494, he was placed under the tuition of the learned Marcello di Virgilio, professor of Greek and Latin literature, and the translator of Dioscorides. How long he remained under the care of this master, or what advantages he derived from his instructions, has not been ascertained. But, five years later, when he had scarcely completed his twenty-ninth year, he was preferred, amongst four competitors, to the employment of chancellor of the second chancery of the Signory; a few months afterwards, he was appointed, by the Signory and the colleges, secretary to the ten magistrates of liberty and peace, which constituted the general government of the republic; and with this employment he continued invested for about fourteen years and a half. His ordinary occupations, when he resided at Florence, comprehended the political correspondence, both internal and external, the recording of the deliberations of the council of magistrates, and the redaction of treaties with foreign states.

But the Florentine government, justly appreciating the talents of Machiavelli, were not long in extending his functions; and he was in consequence successively intrusted with no less than twenty-three foreign legations, besides frequent commissions to the cities dependent on the republic. The first mission on which he was despatched was to France, where he arrived in 1500, soon after the raising of the siege of Pisa. Louis XII. had furnished to the Florentines troops and artillery to form the siege of that place; and the republic had sent to the camp two commissioners, besides its secretary Machiavelli, who carried on the correspondence. The Pisans, however, negotiated with the king, and at the same time gained over the principal officers in the besieging army. The French troops were to be paid by the Florentines, but some delay having occurred in forwarding their pay, they availed themselves of this as a pretext, and having disbanded, the siege was in consequence raised. The French king reproached the Florentines for the disgrace which had thus been brought on his arms; and it was to appease him, and if possible to obtain fresh succours, that they sent to France Machiavelli, and Francisco della Casa, who had been

one of the commissioners in the camp before Pisa. During this negotiation, which lasted five months, the deputies followed the court to Saint-Pierre-le-Moutier, Montargis, Melun, Blois, Nantes, and Tours. They had several audiences of the king, and his minister Cardinal d'Amboise; but these led to no satisfactory result. The envoys were continually met with the same reproaches, and the court was only appeased by the reimbursement of the sums which the king had advanced to the troops.¹

In the year 1502 Machiavelli was sent to the Duke di Valentino (Cesare Borgia) at Imola, and next to Rome. He also went a second time to France, and afterwards to Siena, to Piombino, and to Perugia. In 1507 he proceeded by Geneva to Constance, and from thence to Bolzano, at that time the residence of the Emperor Maximilian, with whom he treated of important affairs. The relation of this mission is printed amongst his complete works, under the title of *Rapporto di cose della Magna, fatto questo dì 17 giugno 1508*. In 1510 he re-appeared in France, and, after passing about two months at Blois, witnessed the opening of the national council at Tours. A fourth mission to the court of Louis XII. is commonly referred to the following year, 1511; but it appears uncertain whether it was actually undertaken. It may with truth be said, however, that if Machiavelli failed to secure the complete independence of his country, this proceeded from no fault of his own; inasmuch as the accomplishment of such an object would have required more confidence on the part of his fellow-citizens, greater harmony between the different opinions which then divided the city, and times less turbulent and unpropitious. But the glory cannot be denied him of having attempted this noble enterprise, and devoted to its accomplishment all his genius, and all the influence which he was permitted to exercise in the conduct of public affairs.

This is fully established by his political correspondence, which, besides, is in the highest degree valuable and interesting. His despatches, indeed, form one of the most amusing and instructive collections extant. In them we meet with none of that mystical and verbose jargon which is so common in modern state-papers. The narratives are clearly and agreeably written, and the remarks on men and things are equally shrewd and judicious. We are introduced into the presence of men who, during twenty years, swayed the destinies of Europe. Their wit and their folly, their gloom and their gaiety, are alike exposed to us; we are admitted to overhear their familiar talk, to see the masters of the world in undress, and to observe the manifestations of their real characters. It is interesting and curious to recognise, in circumstances which commonly elude the notice of historians, the feeble violence and the shallow cunning of Louis XII.; the bustling insignificance of Maximilian, a prince afflicted with an impotent desire of renown, rash yet timid, obstinate yet fickle, always in a hurry, yet always too late; the fierce and haughty energy which gave dignity to the eccentricities of the magnificent Julius; and the soft, smooth, calm, graceful manners which masked the insatiable ambition and deadly hatred of Cesare Borgia. The meeting of the Florentine secretary and the Duke di Valentino, of the greatest speculative and the ablest practical statesman of the age, is a memorable occurrence in the history of both. Upon two important occasions Machiavelli was admitted to the society of Borgia; once, at the moment when his splendid villany had achieved its most signal triumph, when he caught in one snare, and crushed at one blow, all his most formidable rivals;² and again when, exhausted by disease, and overwhelmed by misfortunes, he

Machia-
velli.

was the prisoner of the deadliest enemy of his house. These interviews are fully described in the correspondence. Several writers have supposed that there existed a close and intimate connexion between these remarkable men, and the secretary-envoy has even been accused of prompting the crimes of this artful and merciless tyrant; but, from the official documents, it is evident that their intercourse, though ostensibly of an amicable, was in reality of a hostile description. "It cannot be doubted, however," says an able writer, "that the imagination of Machiavelli was strongly impressed, and his speculations on government coloured, by the observations which he made on the singular character, and equally singular fortunes, of a man who, under such disadvantages, had achieved such exploits; who, when sensuality, varied through innumerable forms, could no longer stimulate his sated mind, found a more powerful and durable excitement in the intense thirst of empire and revenge; who emerged from the sloth and luxury of the Roman purple the first prince and general of the age; who, after acquiring sovereignty by destroying his enemies, acquired popularity by destroying his tools; who had begun to employ for the most salutary ends the power which he had attained by the most atrocious means; who tolerated within the sphere of his iron despotism no plunderer or oppressor but himself; and who fell at last, amidst the mingled curses and regrets of a people, of whom his genius had been the wonder, and might have been the salvation."¹ Some of the crimes of Borgia, which appear to us the most revolting, would not have been viewed with equal horror by an Italian of the fifteenth century; and, besides, patriotic feeling might induce Machiavelli to regard with indulgence and regret the memory of the only leader capable of defending the independence of Italy against the confederate spoilers who were then plotting the dismemberment of that divided and unhappy country.

But whilst Machiavelli deeply regretted the misfortunes of his country, he clearly discerned the cause and the remedy of these. It was the military system of the Italian people which had extinguished their valour and discipline, destroyed their independence, and rendered their wealth an easy prey to every foreign plunderer. Machiavelli projected a scheme for abolishing the practice of employing mercenary troops, and organizing a national militia; and the exertions which he made to accomplish this grand object are alike honourable to his understanding and his patriotism. He studied with assiduity the art of war, and made himself master of all its details.² When levies were decreed, he flew from place to place to superintend the execution of his design, and availed himself of every circumstance which could contribute to its success. For a time the scheme promised well, and the new troops acquitted themselves respectably. But the fury of parties continued to increase, and the tide of misfortune came on before the barriers which should have withstood it were prepared. The emperor and the pope wished to re-establish the Medici, and the moment was favourable for such an enterprise. Florence was then governed by the gonfaloniere Soderini, a man equally presumptuous and feeble, who obstinately adhered to France, without discerning that that power was not in a condition to afford him any aid. It was in reference to this inconsiderate policy that Machiavelli observed, "The good fortune of France has made us lose half the state; her bad fortune will cause the loss of our liberty."³ The prediction was not long in being verified. As soon as the French armies had lost their superiority in Italy, the storm burst upon Florence. In 1512, the pope and the

emperor combined against their common enemy, and, contrary to the faith of treaties, imposed a contribution of a hundred thousand florins. Machiavelli flew through the territory of the republic, to examine the state of the fortresses, and organize a vigorous resistance; but all his efforts were unavailing, and divided Florence soon opened its gates to the Medici, who re-conquered at once their property and their ancient authority.

This revolution, which caused the ruin of the gonfaloniere, proved also the signal for the fall of the secretary. The new Signory immediately attacked him in two decrees, dated the 8th and 10th of November 1514. By the one he was deprived, "absolutely despoiled," of his offices of chancellor and secretary to the ten magistrates of liberty and peace; by the other he was exiled for a year to a part of the Florentine territory, which he was forbidden to quit under the penalty of incurring the displeasure of the Signory. A third decree, dated the 17th of the same month, prohibited him from entering the palace of the high and magnificent signors. On this subject Ginguené has omitted some facts. "Machiavelli," says he, "after fourteen years of service useful to his country, was first deprived of his employment, and then confined for a year to the territory of the republic, with a prohibition not to set foot in the palace of the Signory. Nor was this the term, it was in fact only the commencement of his misfortunes." And he adds in a note, that the fate of the secretary was decided by three decrees of the 8th, 10th, and 17th of November. There appears to be some confusion in this statement. The decree of the 17th was evidently a mitigation of that of the 10th. The latter banished him for a year, and intimated to him that he was not to leave the territory of the republic; that is, it ordained him to quit Florence in order to live in the Florentine dominions, exclusive of the city properly so called. The third decree, dated the 17th, only prohibited him from entering the palace of the Signory, without ordaining him to leave the city; but another decree of the same date was published, in which he was permitted to enter the palace during the whole of the day of the 17th; and the same liberty was granted him on the 4th of December 1512, and on the 21st of March and 9th of July 1513. Ginguené has refuted some of the statements published respecting the treatment Machiavelli is alleged to have experienced after the return of the Medici; but it is not the less true, as appears by the subsequent modifications of the original decree, to the extent already stated, that the removal of the secretary was considered as an affair of some difficulty, and one the accomplishment of which required management and address. But when this object had been effected, he found himself exposed to the greatest dangers. Accused of being concerned in the conspiracy formed by Capponi and Boscoli against Cardinal de' Medici, afterwards Leo X., he was thrown into prison, and put to the torture, which he endured with unflinching resolution. "I have been near losing my life," said he, "which God and my own innocence have saved; I have supported all evils, including imprisonment and others." On the accession of Leo X. he was included in an amnesty, and owed his deliverance to the generosity of that liberal and accomplished pontiff.

These terrible trials, which extraordinary courage can alone withstand, attest the energy and the force of character which belonged to the fallen statesman. Instead of yielding to despondency, he sought for an alleviation of his lot in study and in literature; and it is to his misfortunes that we are indebted for the best known of his works, the

Machia-
velli.

Prince, the dialogue on the *Art of War*, his *Histories*, and *Comedies*, which he composed during his retirement at San Casciano, and which, with the collection of his political letters, deserve to be classed amongst the most remarkable monuments of modern literature. From his retreat, however, he wrote to the friends whom he had still preserved, signifying his desire to be again employed in the conduct of affairs; and his wishes in this respect were to a certain extent gratified. After the death of Lorenzo de' Medici, Leo X. who possessed great influence in the government of Florence, recalled Machiavelli, and requested him to point out the means of reforming the administration. In 1521, there was confided to him a mission to the minor brothers at Carpi. He was next ordered to fortify anew the city, and to treat of some affairs with Francisco Guicciardini, then governor of Romagna. Finally, he was employed in the army of the league against Charles V. This commission was the last remarkable occupation of his life. He returned to Florence in one of the last days of May 1527, and having, not long afterwards, suffered much inconvenience from pains in the stomach, he took a medicine in which he had great faith for relieving this disorder; but being soon attacked by violent spasms in the bowels, he expired on the 22d of June, at the age of fifty-eight, after having received all the sacraments of the church. The following letter from his son Pietro to Francisco Nelli, professor at Pisa, annihilates all the fables which have been circulated respecting his death:—"I cannot tell you without tears, that, on the 22d of this month, our father Nicolo died of pains in the bowels, caused by a medicine which he had taken two days before. He was made to confess his sins by the friar Matteo, who kept him company till his death. Our father has left us in great poverty, as you know." Machiavelli was in his person of the ordinary size, his complexion was of an olive hue, and his physiognomy animated and expressive; in conversation he was at once simple and lively, and his repartee was prompt and piquant. Conversing one day with Clodio Tolomeo, the latter said to him, "At Florence the men have less science, and are less learned, than at Siena, always excepting yourself;" to which Machiavelli replied, "At Siena the men are greater fools than at Florence, not even excepting you." Some one having remarked to him that he had taught princes to be tyrants, he replied, "If I have taught princes to be tyrants, I have also taught the people to destroy tyrants." He was interred in the church of Santa-Croce, in the burying-place of his family; but for more than two centuries his bones lay undistinguished, and it was reserved for an English nobleman, Earl Cowper, to pay the last honours to the greatest statesman of Florence, by erecting a monument to his memory.¹

Several writings of the Florentine secretary are regarded as estimable productions of a superior mind; others are considered as pernicious, and containing abominable doctrines. Amongst the latter are the apology for the conduct of the Duke di Valentino, when he caused Vitellozzo-Vitelli and others to be massacred at Sinigaglia (*Il modo tenuto dal Duca Valentino, &c.*); the treatise of the Prince (*Il Principe*); and some detached opinions contained in the Discourses on Titus Livius (*Discorsi sopra la prima deca di T. Livio*), which opinions, forming part of a writing pos-

terior to the composition of the *Principe*, will, as far as possible, be explained in the more detailed exposition which we shall endeavour to give of the object and intentions of the author when he composed that celebrated treatise.

At the head of the works generally admitted to have established beyond all dispute the reputation of Machiavelli as a profound thinker, and a politician of inexhaustible genius, may be placed those letters or despatches, published under the title of *Legazioni*, of which we have already spoken incidentally. Ginguené has observed, in reference to these letters, that one would not willingly read the collection, which he considers somewhat diffuse, but that, in regard to the character and life of the secretary, and the history of his own time, it may be consulted with advantage. In this opinion, however, we cannot by any means concur. The collection is suited to the taste of the age, and the country to which it belongs; nor has this taste materially changed; for even the Italian diplomatists of the present day frequently indulge in similar details, introducing such arguments as they think fitted to support their observations, and to create a favourable impression of their zeal and industry. That the *Legazioni* sometimes descended into minutiae which may be considered as trifling or irrelevant, we readily admit; but even these particulars are by no means devoid of interest; and as to the entire collection, a reader of intelligence cannot peruse it without being at once amused and instructed by it.

The seven books on the Art of War (*Dell' Arte della Guerra*) show that Machiavelli was profoundly conversant with the principles of military science. An Italian writer, advertent to this circumstance, observes, that such knowledge is not only wonderful in a man devoted to civil occupations, but might even be considered as extraordinary in an old general. According to the author of the preface to the edition of 1813, Machiavelli had acquired this insight into military science in consequence of profound meditations on the works of the ancient Romans, who may be regarded as the first masters of the art of war; and, in fact, the combinations of the secretary have constant reference to those of Vegetius. His principal object was to establish the superiority of infantry, at a time when this branch of the service had fallen into general discredit; and his theories fortunately attracted so much regard, that to him may, in a great measure, be attributed the return of sound tactics, and the perfection to which the art of war subsequently attained. Algarotti, in his fourth discourse on the studies of Palladio, gives us to understand that that celebrated architect learned the military art in the writings of the Florentine secretary; Frederick II. has described, in agreeable verses, some of his military precepts; and there is a French work, entitled *Instructions sur le fait de la Guerre, extraites des livres de Polybe, Frontin, Végèce, Machiavelli, et plusieurs autres bons auteurs*, Paris, 1563. Of the tactics of Machiavelli it is not necessary to express here any opinion. But the treatise is able and interesting; as a commentary on the history of the times it is invaluable; whilst the ingenuity, grace, and perspicuity of the style, and the eloquence and animation of particular passages, must give pleasure even to readers who take no interest in the subject which the author treats with so much skill and ability.²

The *Discorsi*, written about the year 1516, the epoch of

¹ This monument, which is the work of Spinazzi, bears the inscription, *Tanto nomini nullum par elogium, Nicolaus Machiavelli obiit* A. P. V. MDXXVII.

² The treatise on the Art of War is in the form of a dialogue, and the opinions of the writer are put into the mouth of Fabrizio Colonna, a nobleman of the ecclesiastical state, and an officer of distinguished merit in the service of the king of Spain. After some preliminary conversation, Fabrizio expresses his regret that those who in later times affected the manners of the old Romans, should select for imitation their most trifling pursuits. This leads to a discourse on the decline of military discipline, and the best means of restoring it. The institution of the Florentine militia, to which we have already alluded, is very ably defended; and several improvements are suggested in the details.

The Swiss and the Spaniards were at this time regarded as the best soldiers in Europe. The Swiss battalion consisted of pikemen in deep formation, and bore a close resemblance to the Grecian phalanx. The Spaniards, like the soldiers of Rome, were armed

Machia-
velli.

Machia-
velli.

his disgrace, prove that the principles of the author were uniform and constant, and that his views and observations had always a character of justness, depth, and gravity. The Roman republic, in its constitution and its establishments, contained the germs of its greatness; and the inroads committed upon these were the causes of its decline. Machiavelli followed this fatal progress beyond the history of Livy; he discerned and meditated on it in the *Annals* and in the *History* of Tacitus. He there found not only facts, but results; a manner and a style, which he adopted as models. Tacitus became his master in the art of observing, and also, in one sense, in the art of writing; what he had acquired in the study of the former of these two great historians he carried to the school of the latter; and it may be said that he learned from Tacitus to read and explain Livy. After having laid the foundations of his work on the history of Rome, Machiavelli employed himself in following Livy step by step in the perusal of that history; stopping short at every thing which suggested a reflection, or indicated the application of a principle. The text of the historian disappears, or is but rarely cited; actions, institutions, and laws, are alone discussed. The objects of comparison, ancient as well as modern, spring up, so to speak, every instant; luminous results are thence deduced; and an inexhaustible variety of facts continually supports the evidence of the reasonings and the solidity of the maxims. Throughout we discover a mind habituated to profound meditations, and a firmness of soul tried and exercised by the storms of liberty. See, for example, to what he reduces, in his fourth chapter, all the noise made by the quarrels between the senate and the Roman people, which he does not hesitate to regard as the primary cause of the liberty of Rome. Observe also, in his seventh chapter, the strong reasons upon which he grounds the utility, or rather the necessity, of public accusations; and with what justness of discrimination he distinguishes, in his eighth chapter, the effect of public accusations, preferred on public grounds, from those of adulation and calumny. In a word, he reasons inductively from history as he finds it, and deduces his conclusions, not from any appeal to general or speculative principles, but from the facts as these are detailed in the pages of the historian. If he errs, it is only because his experience, acquired in a peculiar state of society, does not always enable him to calculate the effect of institutions differing from those of which he had observed the operation; but in regard to all that comes within the sphere of his own observation or experience, his sagacity is seldom at fault, and he may justly be considered as the founder of that science which has been somewhat vaguely denominated the philosophy of history.

The books *Delle Historie Fiorentine*, a work in which he begins by describing the events which brought about the destruction of the Roman empire, are altogether an admirable composition, and entitle Machiavelli to a sepa-

Machia-
velli.

rate place amongst historians, seeing that the ancients have not left any model on which he could form a particular style. The first book displays the science and penetration of the writer; and it may be supposed that Bossuet was filled with admiration of his free, bold, rapid, and independent manner, when he sketched the plan of his *Discourse on Universal History*. The narrative in the seven other books proceeds with the same vivacity; nor can the most careless reader fail to receive from it a vivid and faithful impression of the national character and manners of the Florentines. This work was undoubtedly the last of the author. He is believed to have completed it in 1525; and it was his intention, we are told, to continue it, which is rendered probable by the fragments collected after his decease. The general character of Machiavelli's style, particularly in the *History* and in the *Life of Castruccio*, is elegance and simplicity. He is always full of grace without artifice, and of elegance without insipidity; he is clear without being verbose, and concise without obscurity or pretension to the mysterious; and such is the transparency of the medium through which his ideas are conveyed, that the actual depth of the current of thought is not at first discernible.

Although the real merit of the Florentine secretary consists in his profound knowledge of the science of government, in which he has not been surpassed either amongst the ancients or the moderns, yet he is also entitled to a distinguished place amongst comic authors. His *Mandragola*, which, according to Voltaire, surpasses all the comedies of Aristophanes, is superior to the best of Goldoni, and inferior only to the best of Molière; in fact, it is the work of a man who, if he had devoted himself to the drama, would probably have attained the very highest excellence, and produced a permanent and salutary impression upon the national taste. By the correct and vigorous delineation of human character, it produces interest without a skilful or pleasing plot, and laughter without the least ambition or affectation. Machiavelli had an exquisite sense of the ridiculous, and his dramatic humour, which has often been compared to that of Molière, and certainly resembles it in comic force, if not in benevolent gaiety and chastened morality, seldom fails to prove effective. The *Clizia* is an imitation of the *Casina* of Plautus, which is itself an imitation of the lost *Καμπανιον* of Diphilus. Machiavelli has executed his task with judgment and taste, accommodating the plot to a different state of society, and dexterously connecting with it the history of his own times. Besides these, the *Maschere*, the *Andria*, and two other comedies without titles, the one in prose and the other in verse, appear amongst the works of Machiavelli. The charming little novel of *Belphegor* is also pleasantly conceived and wittily told; but the extravagance of the satire in some measure injures its effect. Machiavelli was unhappily married; and his wish to avenge his own cause as well a

with the sword and the shield. But the victories gained by Flaminius and Æmilius over the Macedonian kings seemed to prove that the weapons used by the legions were superior to those of the phalanx. And the same experiment had been recently tried with the same result at the battle of Ravenna, "one of those tremendous days into which human folly and wickedness compress the whole devastation of a famine or a plague." In that dreadful conflict, the infantry of Aragon, deserted by their allies, hewed a passage through the thickest of the imperial pikes, and effected an unbroken retreat, in the face of the gensdarmie of De Foix, and the artillery of Este. Machiavelli, struck with these facts, proposes to combine both systems; to arm the foremost lines with the pike, for the purpose of repulsing cavalry, and those in the rear with the sword, as being a handy weapon, adapted to almost every exigency. He expresses the highest admiration of the military science of the ancient Romans, and the greatest contempt for the maxims in vogue amongst the Italian commanders of the preceding generation; he prefers infantry to cavalry, and fortified camps to fortified towns; he recommends the substitution of rapid movements and decisive engagements for the languid and dilatory operations of his countrymen; and he attaches but little importance to the invention of gunpowder, which, he seems to think, ought scarcely to produce any change in the mode of arming or disposing troops. The artillery of those days was ill constructed, ill served, and consequently of little use in the field of battle; this arm was then in a rude, inefficient state, and hence might in a great measure be disregarded in a general system of tactics; but if Machiavelli could have foreseen the improvements which were destined to take place, particularly in point of mobility, he would have been convinced that a change both in the mode of arming and disposing troops would in consequence become necessary, and that the deep formations of ancient times durst no longer be opposed to the ravages of shot, shells, grape, canister, and the other destructive missiles discharged by modern artillery.

Machia-
velli.

that of his brethren in misfortune carried him beyond even the license of fiction.¹

Machiavelli was also a poet, though, in this capacity, he is not perhaps entitled to a very high place. The *Decennali* are merely abstracts in verse of the history of his own times. The style and versification are sedulously modelled on those of Dante; but the manner of Dante, like that of every other great original poet, was suited only to his own genius and his own subject, and did not therefore admit of being copied or imitated. The *Assino d'Oro* and the *Capitoli* are also formed on the same model, and are in every respect superior. The Golden Ass indeed has nothing but the name in common with the romance of Apuleius, which, in spite of its irregular plan and vicious style, is one of the most fascinating books in the Latin language, combining the various merits of Le Sage and Radcliffe, Bunyan and Cr  billon. The poem of Machiavelli, which is evidently unfinished, is copied from the earlier cantos of the *Inferno*; whole lines are transferred without acknowledgment, and all without producing their wonted effect; the flowers of language which have bloomed upon one soil, wither when transplanted to another. Yet the *Assino d'Oro* is not altogether destitute of merit; the allegory displays considerable ingenuity, and there is some vivid colouring in the descriptions.

But, of all the works of Machiavelli, that which has excited the greatest attention is the celebrated treatise entitled *Il Principe*. This production, in which the ferocious Borgia is, according to the supposition of several writers, presented as a model to sovereigns who wish to govern absolutely, has acquired a deplorable reputation in Europe, and made the author himself be regarded by many as an incarnation of the evil principle.² The first edition, known as that of Antonio Blado d'Asola, appeared at Rome on the 4th of January 1532, accompanied with a privilege of Pope Clement VII. and dedicated to Philip Strozzi, the friend of the author. Bayle speaks of an edition of 1515, which no one has seen, there being, in all probability, a misprint in the date. The Giunta reprinted the *Prince* the same year, 1532, and again in 1540. The sons of Aldus also published it at Venice in 1540; and Gabriel Giolito gave an edition of it in 1550. It was successively translated into German, Mont  liard, 1626; twice into Latin; then into French by Amelot de la Houssaye (Amsterdam, 1683, and Hague 1743), and, lastly, by Giraudet in 1799, along with the complete works of the author.

We know not of any work which has excited so much discussion and controversy as this, or which has been so often and so vehemently assailed. The intentions of the author have been variously interpreted. Some, thinking they saw in it a complete system of irreligion, impiety, and tyranny, have cried out "Wolf, wolf;"³ whilst others have demanded that, according to the rules of just criticism, the work should be judged of as a whole, not by detached or disfigured fragments, and that, above all, the disapprobation with which the author always accompanies the exposition of the perverse principles he has developed, should not be dissembled or concealed. Voltaire, writing to the prince-royal of Prussia (20th May 1738), observes: "The first thing I am obliged to advert to is the manner in which you think of Machiavel. Why should you be moved with the virtuous displeasure

which you express against me because I have praised the style of a bad man? It is for the Borgias, father and son, and all those petty princes who require crimes to effect their elevation, to study this infernal policy. It belongs to such a prince as you to detest it. This art, which may be classed with that of the Locustes and the Brinvilliers, may give to some tyrants a temporary sway, just as poison may procure an inheritance; but most assuredly it has never made men either great or happy. What, then, can any one accomplish by pursuing this frightful policy? Nothing but misery to others, and also to himself. These are the truths which should form the catechism of your exalted soul." On the 26th of June 1739, the prince replies to this flattering homage in the true French style, by informing his correspondent that what he meditates against Machiavelism is properly a continuation of the *Henriade*. "It is out of the noble sentiments of Henri IV." says he, "that I am forging the thunderbolt which will crush Cesare Borgia." On the 27th of December, Voltaire renders homage for homage. "We shall at length," says he, "have a book worthy of a prince; and I doubt not that an edition of Machiavel, with this counter-poison at the end of each chapter, will be one of the most precious monuments of literature." "The *Anti-Machiavel*," he adds, "ought to become the catechism of kings, and of their ministers." The book which, in this commerce of flattery, Voltaire denominates *Anti-Machiavel*, is the *Examen du Prince de Machiavel*, by the prince-royal, afterwards king of Prussia, who, in his preface, declares that "he always looked upon the *Prince* as one of the most dangerous works that ever was published," though he afterwards lived long enough to find some of its maxims more convenient and agreeable than he had at first anticipated.

It would be equally endless and impertinent to relate the host of criticisms and apologies, of accusations and defences, of which Machiavelli has been the object, in almost all the languages of Europe. But we shall cite the authority of a judge whom it will not be easy to refute; we mean that of the Florentine secretary himself. Before finishing his treatise of the *Prince*, he wrote to one of his friends, Francisco Vettori, a letter, which discloses without any reserve his real position and his motives, and thus puts an end to all speculation upon the subject. This letter, found in the Barberini library at Rome, was published for the first time by Angelo Ridolfi, in a work entitled *Pensieri intorno allo scopo di Nicolo Machiavello nel libro Il Principe*, Milan, 1810; and Ginguen   has also cited it in his *Histoire Litt  raire d'Italie*, though, for some reason, he has divided it into two parts, giving the one half in the text, and the other half in a note. The first part contains details which may perhaps be considered as ignoble, but which nevertheless make known the peculiar cast of character, as well as the patience, of the author; the second shows him in all the dignity of his talent. We shall only cite the portion which has immediate reference to the subject before us.

"On the approach of evening," says he, continuing the description of his habits and mode of life, "I retire to my dwelling, and enter my cabinet; at the door I divest myself of my peasant's garb, bedaubed with mud and dirt, put on proper attire, and thus decently dressed I enter the ancient courts of men of old. Being well received by them, I fill myself with that nourishment which alone agrees with

Machia-
velli.

¹ The subject of this *novella piacevolissima* cannot be better described than in the words of the argument prefixed: "Befagor arcidivolo    mandato da Plutone in questo mondo, con obbligo di dover prender moglie. Ci viene, la prende; e non potendo soffrire la superbia di lei, ama meglio ritornarsi in Inferno. che ricongiungersi seco." Ben Jonson, in the plot of *The Devil is an Ass*, appears to have taken some hints from this tale, with others from Boccaccio.

² "Out of his surname," says a writer in the *Edinburgh Review* (vol. xlv. p. 260), "they coined an epithet for a knave, and out of his Christian name a synonyme for the devil." For the latter point, the writer has the authority of Hudibras (part iii. canto l.).

Nick Machiavel had ne'er a trick,
Though he gave his name to our Old Nick.

But on this subject the antiquarians, we believe, are by no means agreed.

³ See preface to the French edition of 1813.

Machia-
velli.

me, and for which I was born; nor do I hesitate to converse with them, and to inquire the motives of their actions; whilst they, on the other hand, being full of humanity, reply to my inquiries. For four hours I experience no weariness; I forget all sorrow; I have no dread of poverty, and death no longer alarms me; I transport myself entirely to them; and, as Dante says that *there will never be science unless we retain what we have learned*, I have noted down the substance of my conversation with them, and composed a work, *De Principatibus*, in which I enter as deeply as I can into this subject, with a view to fathom it. I examine what a principality is; how many kinds there are of them; how they are acquired, how maintained, how lost; and if ever any trifle (*ghiribizzo*) of mine gave you pleasure, this should not displease you. It should also be acceptable to a prince, more especially to a new one; wherefore I address it to the magnificent Julius.¹ Philip Casavecchia has seen my treatise, and can inform you in detail of the subject itself, and the arguments I have had with him; and as to myself, I am now occupied in extending and correcting it. You wish that I should abandon my actual mode of life, and go to enjoy yours; I will do so gladly; but I am prevented at present by some affairs which will be settled in about six weeks. The only thing which makes me hesitate is, that, near these Soderini, I shall be obliged, on my arrival, to visit and to speak with them. I am also apprehensive that, upon my return, instead of stopping at my own house, they would make me alight at the barigel (prison); for although this state stands on solid foundations, and enjoys great security, still it is new, and consequently suspicious; nor are there wanting meddling intriguers (*saccenti*), who, like Paul Bertini, would run up a long score, and leave me to pay the reckoning. I beseech you to save me from this danger, and I will by all means come to you at the time I have mentioned. I have been talking with Philip about my little work (the *Prince*), and I have asked him whether it would be proper to give it to the world or not, and, in the event of its being expedient to do so, whether I should bring it myself or send it to you. Were it not published, it is doubtful whether it would ever be read by Julius, and Ardinghelli² would reap the honour of this the last of my works. *The necessity which pursues me, however, urges me to give it, because I am wasting away, and cannot long remain thus without becoming contemptible through poverty. My wish is, that these Medici would begin to employ me, were it only at first to roll a stone.* If I did not then gain their good will, I would have myself only to blame; and by this production, if it be read, people will see that, during the fifteen years I passed in studying the art of government, I have not been a careless or inattentive observer; besides, every one should be eager to employ a man who has acquired experience at the expense of others. Of my fidelity no doubt can reasonably be entertained, because, having always acted with good faith, I am not likely now to sacrifice my character. He who has been faithful and good forty-three years, which is my present age, cannot change his nature. *My indigence sufficiently attests my fidelity and uprightness.*"

This letter requires no explanation or commentary. In it Machiavelli lays bare his whole soul, disclosing without reserve his vexation, his dread of misery, the shame with which he regarded the almost disgusting situation to which

he had been reduced, and his desire at any sacrifice to be again employed in public affairs; nor will the attentive observer, who reads it with care, fail to discover in it a key to the treatise of the *Prince*. Indeed the Italian writers no longer judge of that work without referring to the letter addressed to Vettori.³ It has been said that Machiavelli, despairing of the liberty of Florence, was inclined to support any government which might secure its independence. But this is a refinement wholly unsupported by evidence. The motive which impelled him to the composition of the work was actual indigence, and the prospect of still greater misery; the object which he sought to attain by it was immediate employment under the new masters of Florence, were it only in the first instance to roll a stone. None of the designs which have been so freely imagined, and so confidently ascribed to the fallen secretary, seems ever to have entered his mind. He wanted bread, and thinking that his book, containing the results of his experience and observation, would be acceptable to a prince, especially a new one, he tenders it through Vettori, in the hope that it might be instrumental in saving him from that destitution, the prospect of which he contemplated with so much horror. It is also to be observed that the book, when first published, did not appear to the Italians in the light in which it was afterwards regarded. This is sufficiently evident from the fact that it was printed in virtue of a privilege granted by Pope Clement VII., dated the 23d of August 1531. Italy was then abandoned to such disorders, that some sovereigns hoped to find useful counsels, where, in point of sound morality, they could meet with nothing but odious precepts. At the same time, if we separate the author from his work, it may be observed, that Machiavelli could not know that his work would ever be published. He composed it in the form of a memoir to Lorenzo de Medici; and in his dedication to that young prince, he tells him that he has nothing to offer him but the knowledge of the actions of great men, which he had acquired by long experience in modern affairs; and at the close he adds, "If your magnificence, from the elevated station you occupy, would deign to cast an eye on this lower region, you would learn how unjustly I suffer under the great and continual malignity of fortune."⁴

With regard to the general character of Machiavelli as a writer, and also to the particular question, whether the treatise of the *Prince* was a serious production, or, as Bacon seems to suggest,⁵ merely a piece of grave irony, intended to put nations on their guard against the arts of new and ambitious princes, we refer the reader to the judicious and discriminating remarks upon both points, contained in the First Preliminary Dissertation (pp. 32-37). The *Prince* is an account of the means by which tyrannical power is to be acquired and preserved; it is a theory of that class of phenomena in the history of mankind. Hence it is essential to its purpose that it should contain an enumeration and exposition of tyrannical arts; and on this account it may not only be viewed, but used, as a manual of such arts. A philosophical treatise on poisons would, in like manner, determine the quantity of each poisonous substance capable of producing death, the circumstances favourable or adverse to its operation, and every other information essential to the purpose of the poisoner, though not intended for his use. But the general utility of such a work is,

Machia-
velli.

¹ In point of fact, it is dedicated to the young Lorenzo de' Medici, duke of Urbino, and brother-in-law of Strozzi.

² Nicolas Ardinghelli, distinguished for his acquirements in Greek and Roman literature, died a cardinal at Rome in 1547.

³ On this question, and on other important points relative to Machiavelli, the reader may consult the excellent dissertation of the Chevalier Baldelli.

⁴ Et se vostra Magnificenza dallo apice della sua Altezza, qualche volta volgerà gli occhi in questi luoghi bassi, conoscerà quanto indegnamente io sopporti una grande e continua malignità di fortuna."

⁵ "Est quod gratias agamus Machiavello et hujusmodi scriptoribus, qui aperte et indissimulanter proferant quid homines facere soleant, non quid debeant." (*De Augment. Scient.* lib. viii. c. 2.)

Machine
||
Machin-
-leth.

nevertheless, indisputable; and it is also plain, that a calm unvarnished exposition of tyrannical arts is the bitterest satire against them. Of this Machiavelli himself seems to have been fully aware, when he observed, in reply to a remark which had been made upon this very work, that if he had taught princes to be tyrants, he had also taught the people to destroy tyrants. The *Prince* must, therefore, have had the double aspect here pointed out, though neither of the objects thereby indicated had actually been in the contemplation of the author. It may not be the object of the chemist to teach the means of exhibiting antidotes, any more than of administering poisons; but his pupils or readers may employ his discoveries for both objects. Aristotle had long before given a similar theory of tyranny, but without the suspicion of an immoral intention; nor was it any novelty, in more recent times, amongst those who must have been the first teachers of Machiavelli. The schoolmen followed the footsteps of Aristotle too closely to omit so striking a passage as that to which we have alluded (*Politie*. lib. v. c. 3); and, in fact, Aquinas explains it in his commentary, like the rest, with most unsuspecting simplicity. To us, accordingly, the plan of Machiavelli, like those of former writers, appears to have been purely scientific; and so Lord Bacon seems to have understood him, where he gives him thanks for exposing openly, and without reserve, what princes actually do, not what they ought to do. Great defects of character are no doubt manifested by the writings of Machiavelli. But if a man of so powerful a genius had shown a mind utterly depraved, it would have been a painful and perhaps solitary exception to the laws of human nature; and certainly no depravity can be conceived greater than a deliberate intention to teach perfidy and cruelty. That a man who was a warm lover of his country, who underwent cruel sufferings for her liberty, and who was esteemed by the very best of his countrymen (*e.g.* Guicciardini, his political opponent), should fall into such unparalleled wickedness, may be considered as wholly incredible. The author of the *Prince*, according to the common notion of its intention, could never have inspired such sentiments, had he been a man steeped in depravity, and devoid of all virtuous feeling. To possess the power, however, of contemplating tyranny with scientific coldness, and of rendering it the mere subject of theoretical speculation, must be owned to indicate a defect of moral sensibility. But, to say nothing of the political maxims then received, and of the lenity with which the Italians regarded those crimes which required self-command, address, quick observation, fertile invention, and profound knowledge of human nature, the *Prince* was obviously wrung from the author by the pressure of severe distress; and it is more than probable, that, but for his misfortunes, this famous treatise would never have seen the light.¹

The most ample and esteemed edition of the works of Machiavelli is that of 1813, *Italia* (Florence), in eight vols. 8vo. The best of the French translations is that of Guiraudet and Hochet, Paris, 1799, in 9 vols. 8vo. Those of Gohorry, Paris, 1571 and 1635, of the Sieur de Briencour, Rouen (Paris), 1664, and of Tétard, Haguc, 1691–1696, reprinted in 1743, were very incomplete. Of the English translations of Machiavelli, there is one by Farnsworth, 2 vols. 4to, London, 1762; and another, entitled *The History of Florence, and of the Affairs of Italy, from the earliest Times to the Death of Lorenzo the Magnificent; together with "The Prince," and various Historical Tracts*, London, 1 vol. 8vo, 1847. (J. B—E.)

MACHINE. See MECHANICS.

MACHINLLETH, a parliamentary borough and mar-

ket-town of Wales, Montgomeryshire, near the confluence of the Dulas and Dovey, 35 miles W. from Montgomery. It stands in a pleasant valley, and consists of well built and spacious streets. The chief edifices are the town-hall, built in 1783, and used also as a market-house; and the church, a plain but tasteful building, with an embattled tower. An old house situate here constituted the senate-hall, where the lords and commons of Wales assembled in 1402 at the call of Owen Glyndwr, whom they acknowledged and crowned Prince of Wales. The manufactures of the town are unimportant, comprising chiefly wool and leather; but a brisk trade is carried on in the produce of the county. Machinlleth is supposed to have been the Maglona of the Romans—a military station, erected to overawe the mountaineers. Some Roman remains are found in the vicinity. Machinlleth combines with Newtown, Welshpool, Llanidloes, Montgomery, and Llanfyllin, in returning a member to parliament. Market-day, Wednesday. Pop. (1851) 1673.

MACKENZIE, SIR ALEXANDER, a well-known navigator, was a native of Scotland, and emigrated to Canada at an early age. After being engaged for some years at Fort Chipewyan in the north-west fur trade, he formed the project of reaching, by an overland route, the coast of the Northern Polar Ocean. Starting from Chipewyan on the 3d of June 1789, with a company, in four canoes, he sailed down the Slave River to its outlet in the Slave Lake. He then coasted along the lake, and reaching its western extremity, entered the river which afterwards received his name. Following the stream in its N.W. course, he issued forth into the Great Frozen Ocean on the 15th of July, and had thus achieved an important discovery. Mackenzie returned by the same route, and reached Chipewyan after an absence of more than a hundred days. A more arduous adventure was his overland journey to the North Pacific. He set out in October 1792, sailed for a considerable distance up Peace River, and after braving numerous hardships and dangers, reached his destination in July 1793. He followed the same track on his return. Mackenzie afterwards repaired to England, and published his *Voyages through North America to the Frozen and Pacific Oceans in 1789 and 1793*, 4to, London, 1801. In 1802 his successful enterprises were rewarded by the honour of knighthood. He died in 1820.

MACKENZIE, Sir George, a learned writer and eminent lawyer of Scotland, was the grandson of Kenneth, first Lord Mackenzie of Kintail, and the nephew of Colin and George, first and second Earls of Seaforth. He was born at Dundee in 1636; and after passing through the usual course of education in his own country, he was sent to the university of Bourges, at that time denominated the Athens of lawyers, where he remained three years. Young Scotchmen intended for the bar, having no sufficient means of instruction in the Roman law at home, were then accustomed to frequent the university of Bourges, as in later times they repaired to those of Utrecht and Leyden. He was called to the bar in the year 1656, and had risen into considerable practice before the Restoration. Immediately after the Restoration he was appointed one of the justices-depute,—criminal judges who exercised that jurisdiction which was soon afterwards vested in five lords of sessions, under the denomination of commissioners of justiciary; and in 1661, he and his colleagues were ordained by the parliament "to repair, once in the week at least, to Musselburgh and Dalkeith, and to try and judge such persons as are ther or therabouts delate of witchcraft."

Mackenzie's name appears in the parliamentary proceedings as counsel in almost every cause of importance; and

¹ See *Edinburgh Review*, vol. xxvii., pp. 213, 214.

Mackenzie's connection in that character with the Marquis of Argyll gives no small weight to a passage in his *Memoirs* respecting a circumstance in the trial of that nobleman, which has been the subject of much historical controversy. Between the years 1665 and 1667 he was knighted. He represented the county of Ross during the four sessions of the parliament which was called in 1669. In 1667 he had been appointed lord-advocate in the room of Sir John Nisbet. By that preferment he was, unhappily for his character, implicated in all the worst acts of the Scotch administration of Charles II. Having betrayed some repugnance, however, to concur in those measures which openly and directly led to the re-establishment of Popery, he was removed from his office in 1686, and (which is not a little remarkable) reinstated in 1688, when such measures were still more avowedly pursued.

At the Revolution he adhered to the fortunes of his royal master. Being elected a member of the convention, he supported the pretensions of King James with courage and ability. King William had been solicited by some eager partisans to declare Mackenzie and a few others incapable of holding any public office; but he refused to accede to the proposal. At this critical juncture Sir George Mackenzie composed and delivered his inaugural address on the foundation of the library of the Faculty of Advocates, which he had been mainly instrumental in establishing; a circumstance evincing no inconsiderable degree of firmness and intrepidity. When the death of Dundee destroyed the hopes of his party in Scotland, he took refuge in Oxford, the natural asylum of so learned and inveterate a Tory. But, under the tolerant government of King William, he appears to have enjoyed, in perfect security, his ample fortune, the fruit of his professional labours.

In the spring of 1691, Sir George Mackenzie went to London, where he contracted a disorder which carried him off. He died in St James's Street, on the 2d of May 1691; and his death is mentioned as that of an extraordinary person by several of those who recorded the events of their time. His body was conveyed by land to Scotland, and interred with great pomp and splendour in the Greyfriars churchyard, Edinburgh; a circumstance which shows how little the administration of William was disposed to discourage the funeral honours paid to its most inflexible opponents.

The writings of Sir George Mackenzie are literary, legal, and political. His *Miscellaneous Essays*, both in prose and verse, considered as the elegant amusements of a statesman and lawyer, afford evidence of the refinement of his taste and the variety of his accomplishments. In several of his moral essays, both the subject and the manner betray an imitation of Cowley; and we find Evelyn and Dryden speaking highly of his merits as a writer.

His work, *On the Laws and Customs of Scotland in Matters Criminal*, published in 1678, and dedicated to the Duke of Lauderdale, is an ingenious and plausible production.

The works of Sir George Mackenzie were published at Edinburgh in two volumes folio, in 1716 and 1722. A *History of the Affairs of Scotland from the Restoration of King Charles II. 1660, to the [year] 1691*, was published at Edinburgh in 1821, 4to, under the editorial superintendence of Mr Thomas Thomson, who, in an able preface, related the singular circumstances in which the manuscript was rescued from destruction. It is to be regretted, however, that the portion thus published ends at the very time when the author's means of information became more ample. For many reasons, it would be highly desirable to possess the sequel of these *Memoirs*. (See *Edinburgh Review*, xxxvi. 1.)

MACKENZIE, Henry, was born at Edinburgh, in August 1745. His father, Dr Joshua Mackenzie, was an eminent physician in that city, the author of a volume of *Medical*

and *Literary Essays*; his mother was the eldest daughter of Mackenzie Rose of Kilravock, an ancient family in Nairnshire.

After being educated at the High School and University of Edinburgh, Mr Mackenzie entered upon the study of exchequer business. In 1765 he went to London to study the modes of English exchequer practice. Whilst there, his talents induced a friend to solicit his remaining in London to qualify himself for the English bar; but the wishes of his family, and the moderation of his own unambitious mind, decided his return to Edinburgh, where he ultimately became attorney for the crown. When in London he sketched some part of his first and very popular work, *The Man of Feeling*, which was published anonymously in 1771. The great popularity of this volume gave occasion to a remarkable fraud on the part of a Mr Eccles of Bath, who, taking advantage of the book being anonymous, laid claim to the authorship, transcribed the whole in his own hand, with interlineations and corrections, and maintained his right with such plausible pertinacity, that Messrs Cadell and Strahan, Mr Mackenzie's publishers, found it necessary to undeceive the public by a formal contradiction. *The Man of the World* was published a few years after *The Man of Feeling*, and breathes the same tone of exquisite sensibility. In his first publication he imagined a hero constantly obedient to every emotion of his moral sense. In *The Man of the World* he exhibited, on the contrary, a person rushing headlong into vice and ruin, and spreading misery all around him, by grasping at happiness in defiance of the moral sense. His next production was *Julius de Roubigné*, a novel in a series of letters. The fable is very interesting, and the letters are written with great elegance and propriety of style. In 1777 or 1778, a society of gentlemen in Edinburgh, mostly lawyers, projected the publication of a series of papers on morals, manners, taste, and literature, similar to those of the *Spectator*. Their scheme was speedily carried into effect, and the papers, under the title of the *Mirror*, of which Mr Mackenzie was the editor, were published in weekly numbers. The whole, with the names of the respective authors, were afterwards republished in three duodecimo volumes. To the *Mirror* succeeded the *Lounger*, a periodical of a similar character, and equally successful. Mr Mackenzie was the most valuable contributor to both these works. He contributed forty-two papers to the *Mirror*, and fifty-seven to the *Lounger*. They are distinguished from all the rest by that sweetness and beauty of style, and tenderness of feeling, which form the peculiar character of his writings. In the *Lounger* Mr Mackenzie was the first to appreciate the genius of Burns, in a review of his poems, then recently published, which at once drew the unknown poet from obscurity into the full blaze of a fame that will never die. On the institution of the Royal Society of Edinburgh, Mr Mackenzie became one of its members; and enriched the volumes of its *Transactions* with an elegant tribute to the memory of his friend Judge Abercrombie, and a memoir on German tragedy, the latter of which bestows high praise on the *Emilia Galotti* of Lessing, and on the *Robbers* by Schiller. He also published, in 1791, a small volume containing translations of the *Set of Horses* by Lessing, and of two or three other dramatic pieces. In the *Transactions of the Highland Society* he wrote an account of the origin and proceedings of that association, and published a view of the controversy respecting the poems of Ossian, in which he attempted to vindicate their authenticity; and in the same paper gave a spirited and interesting account of Gaelic poetry. In 1793 he wrote the *Life of Dr Blacklock*, prefixed to the quarto edition of the works of the blind poet; and in 1812 he read to the Royal Society a memoir of John Home, author of *Douglas*, in which he gives a sketch of the literary society of Edinburgh during the latter part of the last century.

Mackin-
tosh.

Mr Mackenzie was not so fortunate as a writer of dramas. Several of his plays were brought out at different theatres, but, though possessed of considerable merit as literary productions, they were not successful on the stage. He wrote several political tracts in the Tory interest, which procured him the countenance and respect of Mr Pitt and other illustrious statesmen of his time, and led to his being appointed, in 1804, comptroller of taxes for Scotland. He died at Edinburgh on the 14th of January 1831, in the eighty-sixth year of his age.

A complete edition of his works was published at Edinburgh, in eight volumes 8vo, in 1808.

MACKENZIE RIVER, a large river of British North America, N.W. territory, rises in the Great Slave Lake, flows in a N.W. direction, and falls into the Arctic Ocean by numerous mouths, after a course of about 900 miles. It is generally about 3 miles in width, and the delta at its mouth, formed by flat alluvial islands, is 90 miles in length, by from 15 to 40 in width. The principal affluents are,—the Mountain and Peel Rivers, and the Great Bear Lake River, which brings down the surplus waters of that lake. Mackenzie River is named after Alexander Mackenzie, by whom it was discovered and navigated in 1789.

MACKINTOSH, THE RIGHT HONOURABLE SIR JAMES, one of the most distinguished men of his time, and who attained to great eminence in literature, philosophy, history, and politics, was born at Aldourie, on the banks of Loch Ness, Scotland, on the 24th of October 1765. His father, Captain John Mackintosh, was the representative of a family which had for above two centuries possessed a small estate called Kellachie, in Inverness-shire. He had served long in the army, which he entered very young, and had been severely wounded at the battle of Fellinghausen, in the Seven Years' War. His mother was Marjory Macgillivray, daughter of Mr Alexander Macgillivray by Anne Fraser, sister of Brigadier-General Fraser, who was killed in General Burgoyne's army in 1777.

In the summer of 1775 young Mackintosh was sent to school at the town of Fortrose; and he had scarcely learned to read when he evinced that predilection for abstract speculation which afterwards formed so prominent a feature of his intellectual character. A gentleman having lent him Burnet's *Commentary on the Thirty-nine Articles*, he perused it with great avidity; and the part which struck him most forcibly, and which he read with peculiar eagerness and pleasure, was the commentary on the seventeenth article, which relates to predestination; a strange subject to engage the attention and interest the understanding of a mere boy. His mind appears to have revolted at the doctrine of eternal decrees of election and reprobation; though surrounded by orthodox Calvinists, he became a warm advocate for free will; and before he had completed his fourteenth year, he was probably the boldest heretic in the county. About the same time he read the old translation of Plutarch's *Lives*, Echard's *Roman History*, and the works of Pope and Swift. His first poetical attempt was a pastoral, or elegy, on the death of his uncle, Brigadier-General Fraser, who fell on the 7th of October 1777; and in 1779 and 1780 his muse was exceedingly prolific, and he even commenced an epic poem on the defence of Cyprus by Evagoras, King of Salamis, against the Persian army.

In October 1780 he entered King's College, Aberdeen, where he remained during that and the three following sessions. At Aberdeen he was by common consent recognised as *inter studiosos facile princeps*; whilst his courteous demeanour, refined manners, playful fancy, and easy flow of elocution, rendered him a general favourite amongst his companions. His chief associate at King's College was the late Reverend Robert Hall, whom the exclusive system of the English universities had forced to seek in this northern

seminary for that academical education which was denied to him, as a Dissenter, in his own country. Like Castor and Pollux, these young men were assimilated in the minds of all who knew them by reason of the equal splendour of their talents, although in other respects they were extremely unlike.

In the spring of 1784, having previously taken his degree of Master of Arts, he finally quitted King's College, "with," he says, "but little regular and exact knowledge, but with considerable activity of mind, and boundless literary ambition;" and in the October following he set out for Edinburgh to commence the study of physic, which he had made choice of as a profession. His arrival in that city opened a new world to his mind. Edinburgh was then the residence of many eminent men; of Adam Smith, Dr Black, John Home, Henry Mackenzie, Dr Cullen, Principal Robertson, Dr Ferguson, Dr Hutton, Professor Robison, Mr Dugald Stewart, and others. He was admitted a member of the Speculative Society, which had been established about twenty years before, and which had general literature and science for its objects. In this exciting atmosphere, speculation rather than study engrossed his attention. Speculators, indeed, are seldom submissive learners. Those who will make proficiency in useful knowledge, must for a time trust to their teachers, and believe in their superiority; but those who too early think for themselves must sometimes imagine themselves wiser than their masters; and hence docility is often extinguished when the work of education is scarcely commenced. After three years spent in Edinburgh, he obtained the degree of M.D. in 1787; and early in 1788 he set out for London. His views were, in the first instance, directed to the medical profession; and he was led from circumstances to contemplate a medical appointment in Russia. But this project, in which he was supported by Mr Dugald Stewart, did not take effect; and it is probable that he felt but little regret at the failure of a scheme which would have removed him from such a scene of interest and enjoyment as London then presented. On the 18th of February 1789 he was privately married to Miss Catharine Stuart, a young lady of a respectable Scotch family; and at the age of twenty-four he found himself with no prospect of any immediate professional settlement, his little fortune rapidly diminishing, and a wife to provide for.

The struggle regarding the regency that followed the announcement of the malady with which the king had been attacked in the autumn of 1788, was the occasion of a pamphlet by Mr Mackintosh, in support of the analogy which Mr Fox endeavoured to establish between the actual state of his majesty and a natural demise of the crown. This seems to have been his first public appearance in the field of politics, for which his mind had now taken a decided turn. About the same time he made the acquaintance of Horne Tooke, whose cause he warmly espoused at the election for Westminster. In the autumn of 1789 he made a tour, in company with his wife, through the Low Countries to Brussels; and, upon his return to London, contributed a number of articles on Belgium and France to the *Oracle* newspaper, with which he appears to have been for some time connected. To the same date must be referred his resolution to devote himself to the study of the law. Hitherto the exercise of his powers had been almost exclusively confined to the columns of a newspaper; but although the most successful efforts of ability are often passed unheeded, or make but a feeble and transitory impression where such are neither looked for nor expected, yet this preliminary training was not without its advantage, and the time now approached when he was to appear before the world in a higher and more independent character.

The extraordinary impression produced by the publication of Mr Burke's *Reflections on the French Revolution*, the

Mackin-
tosh..

Mackin-
tosh.

admiration excited by the work in some quarters, and the vehement indignation with which it was greeted in others, are matters of universal notoriety. By some it was regarded as the most marvellous union of wisdom and genius that had ever appeared in the world, whilst to others it seemed inconsistent with the former life and opinions of the author, notwithstanding that an abhorrence for abstract politics, a predilection for aristocracy, and a dread of innovation, had always been articles of his political creed. A multitude of pamphlets appeared in opposition to it, and each shade of opinion was warmly defended against the common enemy of all change. The great majority of these productions, however, with the exception of Paine's *Rights of Man*, soon fell into oblivion. But whilst Mr Burke was sustaining the attack of the man who had been his fellow-combatant in the American contest for freedom, "a bolt was shot from amongst the undistinguished crowd, but with a force which showed the vigour of no common arm." The *Vindiciæ Gallicæ* was published in April 1791. It had been finished in a great hurry, but, with all its imperfections and defects, it at once placed the author in the first rank of the party in this country who were upholding the cause of France. He was courted and caressed on all hands, his company was eagerly sought for, and, as he himself expressed it, he was for a few months the lion of the place.

In Michaelmas term 1795, Mr Mackintosh was called to the bar, and attached himself to the home circuit. Having thus entered upon a path which, when pursued by the patient steps of genius and industry, so often leads to wealth and distinction, he evidently enjoyed the satisfaction which arises from having in view a constant and honourable occupation. But a severe affliction awaited him in the death of his wife, which took place early in 1797. In 1799 Mr Mackintosh formed the plan of giving lectures upon the *Law of Nature and of Nations*. The benchers of Lincoln's Inn granted him the use of their hall, and he commenced his course by an exposition of the general aim and scope of the undertaking, as well as of the views and feelings which had led him to embark in it. This discourse, which the lecturer was induced to publish, had no sooner issued from the press than commendations poured in upon him from every quarter. Mr Pitt, Lord Loughborough, Dr Parr, and others, united their suffrages in its praise; and it must be confessed that if Mackintosh had published nothing else than this discourse, he would have left a striking monument of his intellectual strength and symmetry. His political opinions, indeed, had undergone a considerable change; and as the tone of these lectures differed materially from that of the *Vindiciæ Gallicæ*, and of the *Letter to Mr Pitt*, this circumstance, together with the support ostentatiously given to them by the ministers of the day and their connections, served to alienate from him several of his old political friends, and to beget suspicions for which there existed no solid foundation.

We come now to an event of great importance in the life of Mr Mackintosh; we mean the trial of M. Peltier, an emigrant royalist, for a libel on the First Consul of France. The address delivered by Mr Mackintosh, as counsel for the accused, formed one of the most splendid displays of eloquence ever exhibited in a court of justice, and it will, beyond all doubt, maintain its place amongst the few efforts of forensic oratory which have survived the occasions that produced them, and are preserved as models for future artists in the same line. "I perfectly approve of the verdict," said Mr. afterwards Lord Erskine; "but the manner in which you opposed it, I shall always consider as one of the most splendid monuments of genius, learning, and eloquence." This trial took place on the 21st February 1803, and some months afterwards, Mr Mackintosh was appointed to the office of recorder of Bombay, vacant by the death of Sir William Syer. Upon his appointment, he received the

customary honour of knighthood, and, early in 1804, sailed with his family for India. His time there appears to have been divided between the discharge of his official duties, literary occupations somewhat irregularly pursued, correspondence with his numerous friends in Europe, and occasional excursions into different parts of the country. The experiment, however, was not successful, in as far as regarded the views which had induced him to solicit the appointment. For although we now know that his mind was in a state of great vigour and activity during the whole of his residence in India, yet he was not enabled to accomplish, indeed scarcely to commence, any of the great works he had contemplated; whilst his habitual inattention to economy prevented any great improvement in the state of his worldly affairs. The consequence was, that he returned to England in 1812, with broken health and spirits, uncertain prospects, and vast materials for works which were never to be completed.

Mr Percival, now at the head of the government, offered him a seat in parliament, and an early promotion to the head of the Board of Control. These tempting offers, however, he declined. But he was almost immediately returned on the Whig interest, as member for the county of Nairn. After this his life scarcely admits of any detailed abstract. He continued in parliament, and true to liberal principles for the remainder of his days. In 1818 he was appointed professor of law at Haylebury, and resigned that situation in 1827. He contributed articles of great value to the *Edinburgh Review*; and in a "Preliminary Discourse" to the present work, being the second in order, furnished a very able history of ethical philosophy, which has been printed separately in 8vo, with a preface by Professor Whewell of Cambridge. After printing several volumes of a popular and abridged *History of England*, which contains more thought and more lessons of wisdom than any other history with which we are acquainted, he left at his death the invaluable fragment of the *History of the Revolution of 1688*, of which a very masterly account will be found in Mr Macaulay's *Crit. and Hist. Essays*, 1852, p. 305. Under Lord Grey's administration, in 1830, he was appointed to a seat at the Board of Control, and cordially co-operated in all the great measures of reform which were then brought forward and carried after a severe struggle. He died in 1832, regretted with more sincerity, and admired with less envy, than any man of his age. In him, perhaps more than in any man of his time, was exemplified that *mitis sapientia*, which formed the distinguishing attribute of the illustrious friend of Cicero, and which wins its way into the heart, whilst it at once enlightens and satisfies the understanding.

With regard to the intellectual character of Sir James Mackintosh, we cannot do better than quote the words in which the able writer who reviewed the *Memoirs of his Life*, by his son, in that journal to which he was so valuable a contributor, has described, or rather portrayed it:—"His intellectual character cannot be unknown to any one acquainted with his works, or who has even read many pages of the memoirs now before us; and it is needless, therefore, to speak here of his great knowledge, the singular union of ingenuity and soundness in his speculations—his perfect candour and temper in discussion—the pure and lofty morality to which he strove to elevate the minds of others, and in his own conduct to conform,—or the wise and humane allowance which he was ready, in every case but his own, to make for the infirmities which must always draw down so many from the higher paths of their duty. These merits, we believe, will no longer be denied by any who have heard of his name or looked at his writings. But there were other traits of his intellect which could only be known to those who were of his acquaintance, and which it is still desirable that the readers of these memoirs should

Mackin-
tosh.

Macklin
||
Macknight.

bear in mind. One of these was that ready and prodigious memory, by which all that he learned seemed to be at once engraved on the proper compartment of his mind, and to present itself at the moment it was required; another, still more remarkable, was the singular maturity and completeness of all his views and opinions, even upon the most abstruse and complicated questions, though raised, without design or preparation, in the casual course of conversation. In this way it happened that the sentiments he delivered had generally the air of recollections—and that few of those with whom he most associated in mature life could recollect of ever catching him in the act of making up his mind in the course of the discussions in which it was his delight to engage them. His conclusions, and the grounds of them, seemed always to have been previously considered and digested; and though he willingly developed his reasons, to secure the assent of his hearers, he uniformly seemed to have been perfectly ready, before the cause was called on, to have delivered the opinion of the court, with a full summary of the arguments and evidences on both sides. In the work before us, we have more peeps into the preparatory deliberations of his great intellect—that scrupulous estimate of the grounds of decision, and that jealous questioning of first impressions, which necessarily precede the formation of all firm and wise opinions,—than could probably be collected from the recollections of all those who had most familiar access to him in society. It was owing, perhaps, to this vigour and rapidity of intellectual digestion that, though all his life a great talker, there never was a man that talked half so much, who said so little that was either foolish or frivolous; nor any one perhaps who knew so well how to give as much liveliness and poignancy to the most just and even profound observations as others could ever impart to startling extravagance and ludicrous exaggeration. The vast extent of his information, and the natural gaiety of his temper, made him independent of such devices for producing effect, and, joined to the inherent kindness and gentleness of his disposition, made his conversation at once the most instructive and the most generally pleasing that could be imagined.” (J. B.—E.)

MACKLIN, CHARLES, an eminent actor and dramatic writer, was born in the county of West Meath, Ireland, about 1690. He was apprenticed to a saddler at the age of fourteen, but not relishing that occupation, he ran away, and after some adventures in England, became badgeman at Trinity College, Dublin, a position which he gave up in 1716 to try his fortune as an actor at the theatre of Lincoln's Inn Fields, London. Macklin's success in this new sphere was very encouraging; and in 1741 he established his fame as a player in the character of *Shylock*, a part to which he gave the tragic reading since universally adopted. He absented himself from the stage from 1753 to 1759, and was engaged as a tavern-keeper and lecturer on oratory and criticism in the Piazza, Covent Garden. Failing in this scheme, he resumed his histrionic art at Drury Lane; but his mind giving way, he was compelled finally to leave the stage in 1789. Macklin died in 1797, at the great age of 107. Of his ten dramatic pieces, the most noted are,—*The Mun of the World*, and *Love à la Mode*. (See his *Memoirs* by Kirkman, 2 vols. 8vo, London, 1799.)

MACKNIGHT, DR JAMES, a learned Scottish divine, was the son of the minister of Irvine, in Ayrshire, and was born in that town in 1721. From the school of his native place he was removed about the age of fourteen to the university of Glasgow, and studied there with great success. At the completion of the ordinary curriculum he repaired to Leyden to study theology. On his return he was licensed as a preacher, and after officiating as an assistant, first at the Gorbals, in Glasgow, and afterwards at Kilmwinning, he was ordained in 1753 minister of Maybole, in Ayrshire. His first work, *The Harmony of the Gospels*, appeared in

1756, and passed through a second edition in 1763. In 1763 this latter year was also published his *Truth of the Gospel History*. So well known had Macknight now become, that he received a diploma of D.D. from the university of Edinburgh, and in 1769 was elected moderator of the General Assembly. During this year he was translated to the parish of Jedburgh; but after the lapse of three years, was promoted to Lady Yester's church, Edinburgh. In 1778 he was transferred to the Old Church in the same city, a charge which he held during the rest of his life. For a long time he had been composing, with persevering and elaborate care, his *New Translation of the Apostolical Epistles, with a Commentary and Notes*. It appeared in 1795, and was praised by the ablest divines of all denominations in Britain. After passing his latter years in a total cessation from literary labour, he died in December 1799. The fifth edition of his *Harmony* was published, London, 1819, and his *Translation*, London, 1809.

MACLAURIN, COLIN, a very eminent mathematician and philosopher, was the son of a clergyman, and born at Kilmoddan, Argyleshire, Scotland, in 1698. In the year 1709 he was sent to the university of Glasgow, where he continued five years, and applied himself intensely to study. His great genius for mathematical learning discovered itself as early as the age of twelve, when, having accidentally met with a *Euclid* in a friend's chamber, he became in a few days master of the first six books without any assistance; and it is certain, that in his sixteenth year he had invented many of the propositions which were afterwards published under the title of *Geometria Organica*. In his fifteenth year he took the degree of Master of Arts, and on that occasion composed and publicly defended, with great applause, a thesis on the power of gravity. After this he quitted the university, and retired to the country seat of an uncle, who had the care of his education, for his parents had been some time dead. Here he spent two or three years in pursuing his favourite studies; but, in 1717, he offered himself as a candidate for the professorship of mathematics in the Marischal College of Aberdeen, and obtained it after a ten days' trial with a very able competitor. In 1719 he went to London, where he became acquainted with Sir Isaac Newton and other eminent men, at which time also he was admitted a member of the Royal Society.

In 1722 Lord Polwarth, plenipotentiary of the King of Great Britain at the Congress of Cambray, engaged him to become tutor and companion to his eldest son, who was then about to set out on his travels. After a short stay at Paris, and visiting other towns in France, they fixed their residence in Lorraine, where Maclaurin wrote his tract on the percussion of bodies, which gained the prize of the Royal Academy of Sciences for the year 1724. But his pupil dying soon afterwards at Montpellier, he returned immediately to his professorship at Aberdeen. He was hardly settled there, however, when he received an invitation to Edinburgh,—the curators of that university being desirous that he should supply the place of Mr James Gregory. He had some difficulties to encounter; but at length these were all surmounted, principally through Sir Isaac Newton, and he was introduced into the university in November 1725.

In the year 1733 he married Anne, the daughter of Mr Walter Stewart, solicitor-general for Scotland. In 1734, Berkeley, Bishop of Cloyne, published a piece called *The Analyst*, in which he took occasion, from some disputes which had arisen concerning the grounds of the method of fluxions, to attack the method itself, and also to charge mathematicians in general with infidelity in religion. Maclaurin thinking himself included in this charge began an answer to Berkeley's book; but, as he proceeded, so many new theories and problems occurred to him, that instead of a vindictory pamphlet, his work became a complete system of fluxions, with their application to the most important

Maclaurin.

problems in geometry and natural philosophy. This work was published in Edinburgh in 1742, in 2 vols. quarto, and is the most considerable of all his works. In the meantime, he was continually bringing forward some performance or observation of his own, many of which were published in the fifth and sixth volumes of the *Medical Essays* at Edinburgh. Some of them were likewise published in the *Philosophical Transactions*, particularly,—1. Of the Construction and Measure of Curves; 2. A New Method of describing all kinds of Curves; 3. A Letter to Martin Folkes, Esq., on Equations with Impossible Roots, May 1726; 4. Continuation of the same, March 1729; 5. On the Description of Curves, with an account of farther improvements, and a paper dated at Nancy, November 27, 1722; 6. An account of the Treatise of Fluxions, January 27, 1742; 7. The same continued, 10th March 1742; 8. A Rule for finding the Meridional parts of a Spheroid with the same exactness as of a Sphere, August 1741; 9. Of the Basis of the Cells wherein the Bees deposit their Honey, 3d November 1734.

When the Earl of Morton set out in 1739 for Orkney and Zetland, to visit his estates there, he desired Mr Maclaurin to assist him in settling the geography of these islands, which was then very erroneous in all maps; to examine their natural history, survey the coasts, and measure a degree of the meridian. Maclaurin's family affairs, and other connections, would not permit him to do this; he, however, drew up a memorial of what he thought necessary to be observed, furnished the proper instruments, and recommended Mr Short, the optician, as a fit person for the management of them. He had still another scheme for the improvement of geography and navigation, of a more extensive nature, which was not destined to succeed, viz., the opening of a passage from Greenland to the South Sea by the north pole.

In 1745, having been very active in fortifying the city of Edinburgh against the Highland army, he was obliged to fly from thence to the north of England, where he was invited by Herring, then Archbishop of York, to reside with him during his stay in this country. In this expedition, however, being exposed to cold and hardships, and naturally of a weak and delicate constitution, he laid the foundation of an illness which put an end to his life, in June 1746, at the age of forty-eight.

Mr Maclaurin was a good as well as a great man, and his peculiar merit as a philosopher consisted in this, that all his studies were accommodated to general utility; and we find, in many places of his works, an application even of the most abstruse theories to the perfecting of the mechanical arts. In his lifetime, however, he had frequent opportunities of serving his friends and his country by his great skill. Whatever difficulty occurred concerning the constructing or perfecting of machines, the working of mines, the improvement of manufactures, the conveying of water, or the execution of any other public work, he was at hand to resolve it.

Of his works, we have mentioned the *Geometria Organica*, in which he treats of the description of curve lines by continued motion. We need not repeat what has been said concerning the paper which gained the prize of the Royal Academy of Sciences in 1724. In 1740 the academy adjudged him a prize, which did him still more honour, for solving the motion of the tides from the theory of gravity,—a question which had been given out the previous year, but without receiving any solution. He had only ten days to draw up this paper, and could not find leisure to transcribe a fair copy, so that the Paris edition of it is incorrect. He afterwards revised the whole, and inserted it in his *Treatise of Fluxions*, as he did also the substance of the former paper. These, with the *Treatise of Fluxions*, and the pieces printed in the *Philosophical Transactions*, of

Macneill.

which we have given a list, are all the writings which Maclaurin lived to publish. Since his death, two more volumes have appeared, containing his *Algebra*, and his *Account of Sir Isaac Newton's Philosophical Discoveries*. His *Algebra*, though not finished by himself, is yet allowed to be excellent of its kind, containing, in a volume of no great bulk, a complete elementary treatise of that science, as far as it had then been carried. (See the Fourth and Fifth DISSERTATIONS prefixed to this work.)

MACNEILL, HECTOR, a distinguished Scottish poet, born on the 22d of October 1746, at Rosebank, on the Esk, and almost amongst the classic woods of Hawthornden, was descended from an old respectable family in the south of Argyllshire. Pecuniary circumstances forced his family from this choice retreat, to occupy a farm on the banks of Loch Lomond, where part of the boyhood of Hector was spent.

His early education, with the exception of a short time spent at school in the neighbourhood, was solely conducted by his father at home, who, along with the common branches, carefully imbued his mind with piety and good morals, and, with parental fondness and pride, also encouraged his boyish passion for the muses. Preparatory to going to Bristol to the house of a wealthy mercantile relative, young Hector was, at the age of twelve, sent to Glasgow for two years, to acquire those branches immediately applicable to a commercial life. On his arrival at Bristol, he was occupied for a short time in the counting-house of his relative, and in completing his commercial education previously to his departure for the West Indies. After spending six years in Antigua and Granada, he returned to his native land with the acquisition of the French language, but with no more wealth than when he departed.

Both his mother and sister had died in his absence, and his father did not survive his return above a year and a half. The small inheritance to which he thus succeeded he sunk in an annuity, which, however, he unfortunately lost by bankruptcy.

In this emergency, through the interest of a friend in London, he was appointed to the office of assistant-secretary in the flag-ship of Admiral Geary. Having made two cruises, he resigned this situation, and soon afterwards undertook the same office in the flag-ship of Sir Richard Bickerton, appointed to the East India station. During this service he was present in the last naval engagement with the able French commander Suffrein.

Before leaving India he visited Surat, and the sculptured excavations of Elephanta. An account of these singular remains he afterwards published in the *Archæologia* in 1787. Neither enriched with the gold of India, nor secured in a competence by a permanent appointment, he returned to Scotland after an absence of five years.

He retired for two years to a humble residence in the neighbourhood of Stirling, where he produced the beautiful descriptive poem of *The Links of Forth*.

The exhausted state of his pecuniary resources, however, compelled him to revisit the West Indies, where he was appointed to an office in the custom-house at Kingston, Jamaica; but the debilitating effects of fever, and other circumstances connected with his duties, induced him to return to his native country. At the request of his friend Dr Currie, he drew up an impartial statement *On the treatment of the Negroes*, which was published at Liverpool in 1788.

Upon his passage home he composed the second canto of the sweetly wild poem of *The Harp*, founded on a tradition of the Hebrides, and communicated to him by Graham of Gartmore, with whom, on his return to Stirlingshire, he lived for nearly two years.

Being afflicted with a nervous disorder, which, by im-

Macnish
||
Macon.

proper treatment, continued about six years, he fixed his residence for a time in a cottage near the field of Bannockburn. Here, while suffering greatly from his malady, he composed *Scotland's Skaithe*, the happiest effort of his genius.

In the hope of recovery from his long-protracted complaints, although by many deemed irremediable, he again sailed for Jamaica. This voyage happily contributed alike to restore his health and to afford him a future competence. By the death of one of the companions of his boyhood, the Grahams of Three-Mile-River, he now received a legacy, and the surviving brother settled on him an annuity for life. Under his friendly roof, previously to his return, he wrote *The Scottish Muse*, descriptive of the various vicissitudes of his own poetical life.

With the well-deserved emoluments of his poetical labours, and another bequest of an intimate medical friend in Jamaica, he returned to Scotland, and spent the evening of his days in the capital of his native land, in the enjoyment of publicly awarded honour, lettered ease, and comparative affluence. Here he published *The Pastoral or Lyric Muse of Scotland* (1808), also two satirical poems, entitled *Town Fashions* (1810), and *Bygone Times and Late Come Changes* (1811). His last literary efforts were *The Scottish Adventurers* (1812), and an unpublished autobiography in three volumes, which has been the chief guide in this brief account. Such were the calm labours of the years spent in Edinburgh, till the 15th March 1818, when he died at an advanced age, leaving a name endared to his countrymen, and embalmed in the song of his fatherland.

From his attachment to truth, he was free, undisguised, and even severe; quick in temper, yet serene and social; proudly honourable, yet warm and benevolent. True to nature and feeling, as a poet he excels in the simple and pathetic; and though his humour and satire be less successful, his manner is serious and his aim uniformly well directed.

A selected edition of his poetical works was published at Edinburgh (1812), in two vols. 12mo. (T. A.)

MACNISH, ROBERT, M.D. and LL.D., was born in Glasgow in 1802, where he practised as a physician, and made extensive contributions to magazine literature under the name of "The Modern Pythagorean." He found leisure also to produce some works of very considerable merit on subjects demanding much patient inquiry and thoughtful sagacity. The best known of these are his *Anatomy of Drunkenness*, *Philosophy of Sleep*, *Metempsychosis*, and *Book of Aphorisms*. He died in 1837.

MACON (the ancient *Matisco*), a town of France, capital of the department of Saône-et-Loire, is situate on the declivity and at the foot of a hill, on the right bank of the Saône, which is here crossed by an old stone bridge of 12 arches, 38 miles N. of Lyons. The town, though pleasantly situate, is ill built, the streets being generally narrow, crooked, and ill paved, and the houses, though mostly of stone, of a dull and sombre appearance. The ramparts that formerly surrounded the town have been laid out in public walks. A handsome quay extends along the bank of the river. The chief public buildings are,—the town-hall, containing a theatre and public library, the old episcopal palace, now the residence of the prefect, the general hospital, the prison, and some of the churches. Macon is the seat of tribunals of primary instance, and of commerce; and has a communal college, society of arts and agriculture, school of design, and a primary normal school. It has no manufactures of importance, being principally dependent on its trade in wine, the produce of the vicinity. Pop. (1851) 12,653.

MACON, a town of the United States of North America, capital of Bibb county Georgia, on both sides of the Ocmulgee, here crossed by a bridge 380 feet in length, 30

miles S.W. of Milledgeville. Being situate at the head of the river navigation, Macon has been steadily increasing in importance. In 1822 it was little more than a village, but now has become the third town in Georgia, both as regards commercial importance and population. Its chief public buildings are,—a court-house, market-house, and a Wesleyan female college founded 1839. Cotton is the staple trade, and is shipped here for the sea-coast in large quantities. In the vicinity there is a much-admired cemetery and a curious mound, supposed by some to be artificial. Pop. (1850) 5953, (1853) about 7000.

MACPHERSON, JAMES, the translator of Ossian, was born at Kingussie, in the county of Inverness, in 1738. He received his school education at Inverness, and afterwards studied at King's College, Aberdeen. In 1758, while schoolmaster of his native village, he published his *Highlander*, a heavy poem in six cantos, which met with no success. On becoming tutor afterwards to the son of Graham of Balgowan, he met Home, the author of *Douglas*, at Moffat, to whom he showed certain verses claiming to be translations of old Gaelic poetry. By the kindness of Home these pieces were submitted to the perusal of Dr Blair, and having elicited the admiration of that critic, were published in 1760, under the title of *Fragments of Ancient Poetry, collected in the Highlands of Scotland, and translated from the Gaelic or Erse Language*. This performance rendered Macpherson exceedingly popular, and gained for him the patronage of such men as Hume and Dr Robertson. So keenly had this specimen of old Celtic literature excited the public curiosity, that money was subscribed to enable Macpherson to rescue what fragments of traditionary poetry yet lingered among the Scottish Highlands. Accordingly he set out, and after exploring the mainland and the isles, published as the result of his tour, *Fingal; an Ancient Epic Poem, in six books, with several other Poems, by Ossian, the son of Fingal*, 4to, 1762; and *Temora, in eight books, with other Poems, by Ossian*, 4to, 1763. These works were read with avidity, were translated into several European languages, and materially increased both the wealth and the fame of Macpherson. Yet even at this early period the enjoyment of his good fortune began to be disturbed by that controversy regarding the authenticity of Ossian which remains unsettled even at this present day. In 1794 he accompanied Governor Johnstone as his private secretary to Pensacola; and after resigning this situation, and holding official appointments at Florida and the West Indies, he returned to England in 1766. Settling down in London, and resuming his literary pursuits, he produced, in 1771, *An Introduction to the History of Great Britain and Ireland*, 4to. The wound which the publication of this work inflicted upon the fame of the author was by no means healed by the prose translation of Homer's *Iliad*, which he produced in 1773. In 1775 he published *The History of Great Britain from the Restoration to the Accession of the House of Hanover*, in 2 vols. 4to. Appointed soon after this to defend the proceedings of the government towards America, he wrote a pamphlet entitled *The Rights of Great Britain Asserted against the Claims of the Colonies*, 8vo, 1776. In 1779 he produced his *Short History of the Opposition during the last Session of Parliament*, a work which so favourably impressed the public that they generally ascribed it to Gibbon. On his appointment soon afterwards to the lucrative office of agent to the Nawab of Arcot, Macpherson began to ply his facile pen in the treatment of Indian affairs. In his official capacity he sat in parliament as member for Camelford during several years, but never spoke in the house. Towards the close of his life, his declining health induced him to remove to Belleville, a seat which he had bought in his native Strathspey. He died there on the 17th February 1796. In accordance with his own re-

Macpher-
son.

Macquer
||
Madagas-
car.

quest, he was buried in Westminster Abbey, and a monument was erected to his memory on a conspicuous site within his own grounds.

It is now generally agreed that Macpherson caught the spirit of his Ossianic poetry from the tales of the old Celtic bards, but often supplied lacunas in the work from his own invention. To him, therefore, we must ascribe many of the weird images and flowing sentences which sometimes characterize it, as well as the pointless verbiage and false description that often render it irksome.

MACQUER, PIERRE JOSEPH, an eminent chemist, was born at Paris on the 9th of October 1718. He was member of the Academy of Sciences and professor of pharmacy, and was engaged in the *Journal de Sçavans* for articles in medicine and chemistry. With the last of these sciences he was intimately acquainted. He had a share in compiling the *Pharmacopœia Parisiensis*, published in 1758, in 4to, and wrote various valuable works on chemistry. His *Dictionnaire de Chimie* was translated into English by Keir. He died at Paris in 1784.

MACROBIUS, AMBROSIIUS AURELIUS THEODOSIUS, an ancient Latin writer, lived about the beginning of the fifth century. In the preface to his *Saturnalia* he tells us that Latin is not his mother tongue; and from the Græcisms that abound in his style, we infer that he was a Greek. The opinion that he was a Christian rests on no sure basis, and is rendered doubtful by the warm sympathy which is lavished in the work above mentioned on the sanctity and religious opinions of the heathen priest Prætextatus. He had a son, Eustathius, to whom he addressed the introduction to his *Saturnalia*. Nothing more is known respecting him. Only three of the works of Macrobius are extant. His grammatical treatise *De Differentiis et Societatibus Græci Latinique Verbi*, is known to us merely under the form of an abstract by a certain author, Joannes. In his *Commentarius ex Cicerone in Somnium Scipionis* he discourses on the tenets of the later Platonists touching the constitution of the universe. His principal work, *Saturnaliorum Convivialium Libri VII.*, is a collection of heterogeneous discussions on the Saturnalia and the Roman deities, on jesting and feasting, on the poetry of Virgil, and on the physiology of the human frame. The best editions of Macrobius are those of Gronovius, 8vo, Leyden, 1670; and the Bipont, 2 vols., 1788.

MACROOM, a market-town of Ireland, county of Cork, on the River Sullane, 21 miles W. of Cork. It consists chiefly of one long street, occupied chiefly by cabins and other mean dwellings. The principal buildings are,—the parish church, Roman Catholic chapel, school-house, market-house, session-house, bridewell, dispensary, and work-house. Market-day, Saturday. Pop. (1851) 3727

MADAGASCAR, a large and important island in the Indian Ocean, about 300 miles from the coast of Africa, from which it is separated by the Mozambique Channel. Cape Amber, its northern extremity, is situate in S. Lat. 12., whence it extends southward, slightly inclining to the W., about 937 English miles, to Cape St Mary, in S. Lat. 25. 40. Its extreme western shore is in E. Long. 43. 10., and its most easterly cape in E. Long. 50. 30. The breadth of the island increases gradually from the northern point to the centre, where it is widest, being about 350 miles across; while the average breadth of the southern portion is about 250 miles. It has been estimated to contain 150,000,000, or even 200,000,000 acres of land; and though such estimates, in the absence of actual measurements, can only be regarded as approximations to its actual extent, its surface is equal to three-fourths of the territory of France, and larger than Great Britain and Ireland combined.

The coasts of Madagascar contain a number of bays and harbours, some of them spacious and sheltered, and capable of affording excellent and secure anchorage for shipping of

the largest dimensions. Among these may be specified Diego Saurez Bay, or British Sound, near the north-eastern extremity of the island; Port Loquez, Antongil Bay, and the Bay of St Luce, on the eastern coast. Tamatave and Foule Pointe, though the most frequented ports on this side of the island, are only open roadsteads, protected by reefs of coral. St Augustine's Bay, a port of frequent resort for vessels trading to the N.W. coast, and ships engaged in the whale fishery, Tolia Bay, Boiana, Bambetoka, Majambo, Narcenda, Pasandava, and Chimpaykee Bays, are the most important on the western coast. There are several small islands adjacent to the northern shores of Madagascar, of which St Mary's, 31 miles long and 2 or 3 miles broad, on the eastern coast, and Nosibé, a somewhat larger and more compact island, on the N.W. coast, are the most important. Both these small islands are now occupied by the French, the latter having been taken possession of by them in 1840.

The physical aspect of the country is varied. The shores of the northern parts, and some portions of the south-eastern coast, are bold and precipitous,—the high land and mountain ranges extending to the sea; but in general the coast is low and flat for a distance varying from 10 to 50 miles on the eastern side of the island, and from 50 to 100 miles in some parts of the western coast. The low land is generally covered with luxuriant vegetation; and trees of large size and abundant foliage often extend to within a few yards of high-water mark. At varying distances from the coast the country rises gradually towards the interior, where the land is highest, being 6000 feet above the level of the sea. The ascent from the low lands along the coast to the high central regions consists, especially on the eastern side, of a succession of ranges of mountains, or hills, running in a direction parallel with the coast, and 500 or 600 feet high. The mountain ranges are occasionally separated by fertile plains of several miles in width, but more frequently by a narrow valley only, or a mountain stream. With one or two exceptions, the loftiest mountains of the island are in the interior, and rise from the most elevated portions of the central provinces. The highest of these is Ankaratra, a basaltic pile, on a range of gneiss or granite mountains, about 50 miles to the S. of the capital. Next to Ankaratra, Andringitra, to the N.W. of the capital, and Angavo, near the boundary, between Ankova and Ankay, about 60 miles to the eastward of the capital, together with Iangogora, near the northern extremity of the island, are reported as the highest mountains in Madagascar, and are computed to be between 8000 and 12,000 feet above the sea.

The valleys are numerous; some of them extensive, fertile, and remarkably beautiful. The soil is occasionally marshy and wet, but is in general the most prolific and extensively cultivated in the country. Belisa, in the country of the Sakalavas, to the S.W. of the capital; Ambolo, in the province of Anosy, to the S.E.; Angavo, situate in Ankay, between the lofty mountain of the same name and Ifady; and Betsimitatatra, to the W. of the capital, are among the most celebrated valleys in the island. They vary from 4 to 10 miles in breadth, and from 40 to 60 miles in length, and are generally populous, fertile, and extensively cultivated. Besides the valleys, there are extensive plains; one to the W. of the capital, being nearly 100 miles across. These are sometimes comparatively barren, but more frequently covered with thick coarse grass.

The country is well watered, even in the high and central regions. The rivers are numerous, and some of them large, winding their way, under different names, 150 or 200 miles from their sources to the sea. The mouths of the rivers are generally choked with sand, and though some of them on the N.W. coast are navigable for small craft for a considerable distance from the coast, they are

Madagas-
car.

Madagas-
car.

but little used for purposes of inland navigation. The Sambaho and Betsibooka are said to be navigable for boats for the distance of 150 miles from the sea. The Ikiopa, Mansiatria, Matetanana, and Mangoro, are among the largest rivers in Madagascar; the greater part of them find an outlet on the western coast. Extensive lakes stretch along the eastern coast for nearly 200 miles, and at intervals communicate with the sea. Others exist in different parts of the island, and are celebrated for their extent or beauty; some of them being 100 miles long, and occasionally studded with islands, and surrounded by the most luxuriant vegetation. Some of them abound with fish, which are highly prized by the inhabitants residing on their borders. Saririaka (literally, image, or portrait of the ocean); Imania, in the Sakalava country; Imanangora, in the province of the Antsianaka; and Itasy, in Imerina, are among the most remarkable.

Fountains and springs are numerous and valuable, especially those situate in the more elevated provinces, where they are called by the people *rano-velona* (living waters). Besides these, mineral waters and medicinal springs, of great reputed virtue, are occasionally met with; and thermal or hot springs, some of unusually high temperature, are of frequent occurrence.

The geology of Madagascar has yet to be examined and described; and little is at present known respecting it, beyond the aspect of some of its more prominent features in the parts most accessible to Europeans. The successive ridges of mountains, or hills, between the eastern coast and the interior, seem to consist of primary rocks; gneiss, granite, quartz, sometimes of a beautiful pink colour, at others in large transparent masses, are frequently met with; basalt and large beds of clay are also to be seen. In the central and southern parts of the island slate formations and limestone, with imbedded fossils, have been found. Iron of excellent quality is plentiful near the surface of the ground in some of the central provinces, and is so abundant in one of the mountains—Ambohimiangavo—that it is called *Iron Mountain*. Coal has also been found on more than one spot in the northern parts of the island. No attempts have been made to ascertain the extent or quality of the coal; but iron has long been wrought by the natives into such implements of war, agriculture, or domestic use, as their grade of civilization required. Copper and other minerals are said to exist in the country; but all the copper that is seen in the possession of the natives seems to have been obtained from foreigners.

The climate is very unequal, both in relation to its salubrity and temperature. In the high northern and central districts it is salubrious, and many very aged people are to be met with among the inhabitants. In the northern regions showers of sleet often fall; and in the central districts the ground is occasionally covered with hoar frost, and ice is seen among the mountains during the winter season. The fluctuations of the temperature are often extreme; the thermometer ranging from 40° to 80° in the same day. The seasons of rain are periodical and regular. The climate of the low lands, and the vicinity of the coast throughout the whole islands, is exceedingly unhealthy. The heat during great part of the year is intense, the rain frequent, vegetation rank and luxuriant, and fevers of an intermittent and typhoid character severe, and very frequently fatal to Europeans and the natives of the more salubrious districts. The miasma is most virulent between the months of November and April, and during this time the natives of the interior avoid visiting the coast, and few trading vessels resort to the ports.

The central districts of the island are comparatively sterile, though some are covered with thick tall grass; but all the low land, the intervening regions, and some of the higher portions of the country, are clothed with verdure,

Immense forests, 40 or 50 miles in breadth, traverse, with occasional interruptions, parts of nearly all the provinces of the island. These forests abound with large and durable timber, suitable for carpentry and ship-building. Woods valuable for cabinet work, viz., a species of mahogany, and ebony, are also met with. But the botany of Madagascar, regarded from a scientific or economic point of view, presents a rich and extensive field as yet scarcely penetrated. Two botanists from Germany, who visited the island more than thirty years ago, mention that among 400 plants which they collected, 100 were new or undescribed species, and 200 new varieties. The plants already known are rare and valuable, and some of them peculiar to the island; among the latter may be mentioned the *Urania speciosa*, or traveller's tree, which not only furnishes to the traveller or the labourer, at all seasons, a cool, sweet, and wholesome beverage, but is also extensively employed in the structure of the native dwellings, as well as for a variety of domestic purposes; the *Sagrus rufia*, which provides clothing for so large a portion of the lower classes of the people; several species of cotton; the poisonous *Tangena*, which has been rendered so destructive of human life among the people; the splendid *Poinciana regia*, and the *Colvillea racemosa*, 40 or 50 feet high, and which, when covered every year, the one with scarlet, the other with yellow flowers, are among the most gorgeous and magnificent of vegetable productions. Also the curious and elegant lattice-leaved plant *Ouvirandra fenestralis*. Several kinds of spices are indigenous, as are also different species of indigo; plants yielding the gum-copal and gum-elastic, and numerous varieties of dye-woods, are also found. Honey and wax abound in the wooded parts of the island.

Among the plants used as food, rice is the most abundant and universal, though arrow-root is the principal article of food among the Sakalavas on the western coast. Besides these, there are yams, manioc, sweet potatoes, and sugar-cane. To these have been added millet, maize, and potatoes. Among the fruits, the cocoa-nut plantain, or banana, of which there are several species peculiar to the island, and of excellent quality; citrons, oranges, melons, mangoes, and peaches.

Domestic poultry are abundant; there are also several kinds of pheasants, and a small species of partridge. The guinea-fowl, both wild and tame, exists in considerable numbers. Turkeys, geese, and ducks, and a superior kind of domestic fowl, have been introduced, thrive well, and are exported in large numbers to Mauritius and the Isle of Bourbon. Water-fowl, in considerable abundance, are found among the lakes and marshy parts of the island. Pigeons and parrots inhabit the woods; and among the feathered tribes birds of the falcon genus are frequently seen. A kind of ostrich is said to resort to the most solitary parts of the island; and the existence of an immense bird in the island is proved by the gigantic fossil eggs which have been found near St Augustine's Bay, and are now in the museum at Paris.

Horned cattle, wild and tame, are the most abundant and important of the quadrupeds. The former, in immense herds, roam over the remote, unfrequented parts of the island, seldom disturbed by the hunters. Tame cattle, which are of the buffalo breed, are reared in great numbers as food and for exportation. Sheep in small numbers are fed in Imerina, and pigs in some of the districts. Wild hogs exist in the woods, together with wild dogs and cats, baboons, monkeys, racoons, lemurs, foxes, and squirrels, and the rare and singular animal the *Cheiromys Madagascariensis*, or Aye-aye, of which only one skeleton has yet reached Europe. Tame dogs are kept in the villages; but cats, being considered creatures of evil omen, are rarely seen, and rats and mice consequently swarm in all the habitable parts of the island. Scorpions are numerous, large, and venomous. Few of the serpents are poisonous, though many are unusually large, and are

Madagas-
car.

Madagas-
car.

said to attack and destroy a quadruped. Crocodiles abound in the rivers and shallow waters, and often prove fatal to travellers and cattle when fording the streams. They are large and powerful reptiles, measuring 15 or 17, and sometimes even upwards of 20 feet in length. In the southern parts of the island they are said to be exceedingly fierce and dangerous, at times attacking and upsetting the frail canoes of the natives, and preying upon the voyagers; yet such is the superstitious feeling of the people towards the crocodile, that though they would seek protection from it by charms or prayers, they would not injure or attempt to kill one, even in self-defence.

Agriculture is but in its infancy. Rice is cultivated extensively, and the plantations wrought and irrigated with commendable industry and skill; other articles are only cultivated to a small extent, and as supplementary to the rice, which is the staple food of the inhabitants. The implement chiefly in use is a strong iron spade, with a long, straight handle. The labours of the field are chiefly performed by male and female slaves, and oxen are not used, either for tillage or as beasts of burden, excepting when they are driven over the fields to pulverize the soil; and the few horses which they possess are kept for riding.

Though the native manufactures are not numerous, they indicate no deficient capabilities in the people. They fabricate articles of jewellery in gold and silver with much taste and skill, and work well in iron and wood. Their matting, platted or woven by the hand, is not only large and strong, but some kinds fine and beautiful in quality and pattern. Their native stuffs, woven from the fibrous parts of the rufia leaves, and their lambas, or native dresses, in cotton and silk, though wrought in the simplest looms, are often beautiful and durable fabrics.

The commerce of the island, though at present but trifling, is capable of almost unlimited extension. The chief articles of export are—cattle, poultry, rice, rufia cloth, matting, a kind of grass hat, woven by hand, light and durable; gums, and bees' wax. Coffee would grow well in many parts of the island, indigo might be produced to almost any extent, and both might furnish valuable articles of export. Good sugar has been made, but at present the cane is only cultivated for purposes of food, or for distilling from its juice a strong, fiery sort of arrac, the use of which is extended among the people, especially at the ports, and threatens to produce the most disastrous consequences. Other articles of export might be produced in a country so fertile and extensive; and rice might, with but comparatively little additional labour, be raised in much larger quantities than it is produced at present. It is scarcely possible to conceive of a soil more adapted for the cultivation of rice than that of many parts of Madagascar, or more fertile than in favourable seasons it often proves; a single bushel of seed yielding, under their most skillful modes of culture, in a favourable season, one hundred bushels of grain. The crop, when ripe, is reaped, dried, and thrashed on the ground. Their process of thrashing consists in taking up large handfuls of rice and straw, and beating the ears on a stone or portion of rock fixed in the midst of a dry, hard, thrashing-floor, prepared for that purpose in some central spot easily accessible from the cultivated fields. When the grain is thrashed, it is carried on the heads of slaves to the granaries of their owners. These granaries vary in structure in different parts of the island. On the eastern coast and to the southward, the grain is stored in small houses raised on posts, with projecting ledges, to prevent the access of rats and mice. At the capital and some of the central provinces, the rice is preserved in granaries built of clay, in the form of a cone, with only one aperture on the summit. Some of these granaries are built above ground adjacent to the dwellings of their owners; others are constructed of the same form and dimensions under ground, the aperture

Madagas-
car.

at the top, generally about a foot below the surface, being covered with a stone, and then the hollow filled up with earth composing the surface of the court-yard, in which the underground granary is usually sunk. Rice by these means is often preserved for a great length of time in excellent condition. With land so fertile and adapted for the growth of such abundant crops of rice as the plantations in the interior often yield, it might be raised for exportation to almost any extent; but the absence of canals and public roads, and all means of land carriage, precludes the possibility of conveying the produce of many of the provinces to the seaports, excepting in comparatively small quantities, and thus impedes very materially the development of the resources of the island. The government has been deterred from constructing or encouraging the formation of public roads, from an apprehension of the facilities they would afford to a hostile force invading the country and seeking to penetrate the interior. The want of good roads, therefore, though detrimental to their commercial interests, is preferred by them as a means of security. This disadvantage might be, to a great extent, compensated in some of the provinces by greater attention to the means of carriage by water. The late Radama commenced the work of connecting some of the principal lakes on the eastern coast by means of a canal, but since his death the work has been discontinued. Boats, better adapted for conveying grain in larger quantities to the places adjacent to the ports, and accessible by water, might be constructed, and would assist in augmenting the exports from the island. Their imports are chiefly cotton and woollen goods, wearing apparel, articles of domestic use, fire-arms, ammunition, wines, and liquors; and to these other articles will doubtless be added as their means of purchasing them increase. The Hovas, the paramount race in the country, exhibit many of the elements of a thoroughly commercial people; keenness in trade seems to be intuitive with many, and the love of bartering almost a passion among all; scarcely any engagement interferes with the market, and multitudes employ themselves in hawking goods of foreign or domestic manufacture about the country for sale. In this occupation many persons of rank and property employ their slaves, giving them a percentage on the amount or the profit of their sales. The dealings of the Hovas are seldom transactions of barter or exchange, but usually money purchases. The only coins they use are Spanish dollars, and very recently five-franc French pieces. For all the cattle exported these silver coins alone are received in payment. The Malagasy have no native currency; and for ordinary use among themselves, the Spanish dollar is cut into halves, quarters, eighths, and smaller portions, even to the seventy-second part of a dollar. The cut pieces of the dollar are weighed in every instance, and a pair of money scales, with their appropriate iron weights, are not only considered essential in every house, but are often seen thrust into the girdles of the men when employed in their ordinary avocations. Money-changers are a distinct class among the traders, and the rate at which whole dollars and cut silver are exchanged fluctuates almost daily at the capital and other principal places, as the one or the other are most in demand. In other parts of the island, especially those remote from the capital or the ports visited by shipping, the trade among the inhabitants is carried on to a great extent by exchange, or barter. Several attempts have been made by the foreign traders to induce the natives to receive gold coin in payment for cattle and other articles, but hitherto without success. The Hovas are not ignorant of the relative value of gold and silver, but at present seem only to value the former for the manufacture of jewellery and other articles of personal ornament.

The government of the country was, until the reign of the late King Radama, exercised by a number of

Madagas-
car.

princes, or rulers, independent of each other. The personal will of each ruler was the supreme law, which all living under his authority were required to obey. This government was nevertheless, to a certain extent, representative, and embodied in its practical working a recognition of the will of the people. A number of the principal persons in each province or territory, governed by a single chief, were always associated with the supreme ruler in administering the government, which was maintained according to certain traditional usages recognised alike by all parties. Besides this, appeals were made on all great occasions to the people, who were summoned to public assemblies, called *kabarys*, when the wishes or requirements of the ruler were made known, and the people were required to express their opinions; and though the latter were generally expected to concur, without questioning, in the proposals that were made, they were thus recognised as parties concerned, and plans were sometimes modified in consequence of the proceedings at the public *kabarys*.

By the natives themselves Madagascar is divided politically into twenty-two provinces, and these provinces often comprise two or three smaller political or territorial subdivisions, as in the case of Ankova, the central province of the island, and the province of the Hovas, which includes Imerina, Imamo, and Vonizongo. Sometimes the province and its chief town, or village, are designated by the same name, as in Mahavelona and Tamatave, though the inhabitants of both these and the adjoining provinces are called Betsimesarakas. At other times the province and its inhabitants are called by the same name, as in Antsianaka and Betsileo. In other instances a large extent of country is called by one name and its inhabitants by another, as in the S.W. coast, where the country was called Menabe, the inhabitants, Sakalavas; and each large division of the island has its own local usages and laws.

The late King Radama succeeded during his reign, which terminated in 1828, in obtaining, by conquest or treaty, the subjection and adhesion of all the independent rulers in Madagascar, and thus became the acknowledged sovereign of the whole island. And although he allowed no authority or law above his own will, even this arbitrary and absolute rule, exercised as it was in carrying into effect his own enactments, and supported, moreover, by the military organizations introduced among the Hovas during his reign, was nevertheless administered with a large measure of regard to previously existing usages among the people. The system of government established by Radama has, with but slight alteration, been continued by his successor. The present government of Madagascar may therefore be regarded as a sort of combination of pure military despotism and limited monarchy; the former, though greatly preponderating, being modified by certain acknowledged requirements from the sovereign, and traditional and hereditary rights and usages on the part of the people. The sovereign of Madagascar claims nominally the right and authority to do whatever he pleases with the lives and property of his subjects; but traditions and customs have in a number of instances the force of law, which the sovereign deems it needful to respect; and to some extent the opinion of the people, as expressed through their subordinate and local authorities, is considered, and their will to a certain extent regarded. For though the power of the sovereign is nominally absolute, and he is lord of the soil, owner of all property, and master of all the people, and disobedience to his orders would be followed by confiscation of property, loss of liberty, and most likely of life, long-established usages seem to require the appearance at least of equity and justice in the proceedings of the ruler, and the exercise of this power conformably with acknowledged rights of the people. No sovereign would feel himself safe whose rule was condemned by the majority of his people; but a sove-

VOL. XIII.

Madagas-
car.

reign whose rule was wise and just would be regarded with admiration and veneration, as a being almost more than human. On one occasion a sovereign of this character was apparently near his death, and the diviners said that a human sacrifice was required for the preservation of his life. When this was made known to the people, an individual came forward and offered to die for the preservation of his sovereign; his offer was accepted, though his life was ultimately spared.

The duties of the sovereign are onerous and varied. He is not only supreme ruler, ordering all affairs, enacting all laws, and superintending their execution; he is also supreme judge, and punishment of death can only be inflicted by his authority; he is likewise commander-in-chief of all the forces of the kingdom; and he is, moreover, chief priest, officiating personally in the religious rites at the national festivals. He has no officially appointed council, but may call to his assistance whomsoever he chooses, consult them unitedly or separately as he pleases, and follow their advice or his own as he deems preferable. Radama, it is said, was accustomed to consult his chief officers repeatedly in reference to any measures of policy which he was contemplating, and then decide according to his own judgment. The sovereignty is hereditary, as are also most of the offices of the government; yet both rank and office are acquired by merit. In both cases they are the gift of the sovereign, but grade in society descends hereditarily. Though the sovereignty is hereditary, the ruling sovereign has the right of nominating his successor, with such limitations and conditions as he may judge fit, and nothing less than armed insurrection would set aside such nomination, if officially or publicly announced to the people. The arming and training the troops of Madagascar according to the European manner, accomplished by Radama about thirty years ago, as well as the uniting of the whole island under one sovereignty, changed to a great extent the system of government, which is now, considering the partial civilization of the people, elaborately organized and highly centralized. The rank in the army is reckoned by numbers, commencing with the privates, whose rank is 1, and rising through all the intermediate grades in the service to that of the commander-in-chief, whose rank is 14, and is the highest beneath the sovereign. The same gradations of rank extend to all civil officers of the government, and impart a military character to the whole. The rank of any individual is derived from the sovereign, by whom it may be increased on account of merit, or reduced by way of fine or penalty for offence. In some of the provinces, hereditary rulers still exercise jurisdiction; but the governors of these are usually appointed by the sovereign, and are at the same time chief commanders of the military posts in the districts. The laws or edicts of the sovereign are proclaimed to the people in the capital, and the country immediately adjacent, by the sovereign in person, or by some of the supreme judges or other high officers. On these occasions the people are summoned to attend, and are generally expected to express their assent, or to propose any alterations they may desire. The laws and requirements of the sovereign are sent to the governors or chiefs of the provinces by regular messengers, and are promulgated publicly to the people, generally in the market-place; and it devolves on the heads of thousands and heads of hundreds to secure their due observance in their respective villages. There is also a sort of military police charged with maintaining order, preventing theft, arresting delinquents, &c.

Justice is administered by magistrates or judges appointed by the sovereign; the sittings of the judges are public, generally in the open air. The ordeal of the *tangena*, or drinking of poison-water, is very frequently resorted to in order to prove the innocence or guilt of the parties accused.

The revenue of the sovereign is limited as compared with

Madagas-
car.

the amount of property in the island, the riches of many of the nobles, as well as the numbers of persons in government employ. The want of a more ample revenue operates unfavourably upon the people, leading often to great oppression,—large supplies, viz., provision for the army, felling timber, quarrying stones, and all kinds of public work, are required to be furnished without any payment whatever. The people are not insensible to the advantages of good government, but would much prefer a better mode of sustaining it, as it is said that a tax, even to one-fourth of the produce of the land, would be less oppressive than the present system. The revenue of the sovereign is derived from spoil taken in war, chiefly cattle and slaves; donations of money on certain occasions, as acknowledgments of sovereignty; a tenth of all the produce of the country; a sort of poll-tax on all slaves; one-fifth of the profits of goods taken to the capital and sold, excepting in public market; and a duty of 10 per cent. on all foreign imports and exports; the first-fruits of harvest, an annual tax on each spade, as a sort of rental for the land cultivated, and a small tax on each house. In addition to these sources of revenue, a portion of all fines imposed by the judges, one-third of the price of all persons sold into slavery on account of debt, and the property of all who die in consequence of drinking the *tangena*, or poison-water, belongs to the sovereign. The court of the sovereign at the capital of the kingdom is maintained in considerable pomp, and with numerous attendants. The troops of the sovereign are estimated at 40,000 men, a considerable portion of whom are armed with muskets; and some idea of the number of government *employés*, and of the progress of education under the patronage of Radama, may be gathered from the fact that, while in the year 1818, when the first missionary arrived in the island, the king (Radama) employed only one writer, in 1836, when the missionaries left, no fewer than 4000 writers were employed by the queen's government.

The religious opinions of the Malagasy are exceedingly vague, indefinite, and crude, their mythology disjointed and fragmentary, and their acts of worship apparently unimpressive and infrequent. Their idols, or objects of superstitious regard, make scarcely any appeal to the senses or feelings, except to their fears; nevertheless, they cling tenaciously to the creed or belief which has been handed down from their ancestors, and surrender themselves unscrupulously to its influence. They are not destitute of ideas respecting a supreme, invisible, and mighty spiritual being, whom they call God; yet it is exceedingly difficult to arrive at the exact ideas which they associate with the word, as it is used for objects utterly incompatible with each other. Their religion seems to consist in a belief in the power of the spirits of their ancestors; hence, the spirits of the ancestors of the reigning family are regarded as among the chief objects of national worship and trust. Other objects of worship seem rather to be charms than idols. Their belief in charms of various kinds is universal, as is also their belief in witchcraft, sorcery, and divination, and likewise in a species of fatalism, or stern, inevitable, immutable destiny. They have no temples, or altars, or priesthood; their visible objects of worship are kept in houses considered sacred, and prohibited, except to certain persons appointed as their keepers. Offerings, or presents, are made to those having the custody of the idols, and requests are preferred; but they are generally brief ejaculations, deprecating anger, and imploring wealth or some other temporal good. Most of their calamities are ascribed to sorcery, or the agency of invisible and malignant beings, against whom charms alone afford protection; and almost every transaction of life, and often even life itself, is dependent on divination; as in the event of birth on days esteemed lucky, or the reverse, in which case it depends on the diviner of the

Madagas-
car.

infant's destiny whether or not it is to be permitted to live. Their ordeals are exceedingly sanguinary, delusive, and cruel, and their religion has in no degree tended to enlighten the understanding, or improve the character of its adherents; while it has, so far as it has operated, retarded their civilization. Their ideas of a future state are as dark and unsatisfactory as their religion during their present life; not that they are destitute of all belief of a future life, but it is uncertain, unsatisfactory, and unwelcome, and death at times as alarming as irresistible. The ceremonies connected with death and interment are numerous and costly; and the tombs of their chiefs (piles of stones of large dimensions) are among the most striking and impressive of their antiquities.

It has been said, that at one time the Arabic language was understood and written by a few individuals, probably of Arabic descent, residing on the south-eastern coast; but previously to the year 1820 education and letters were unknown in Madagascar; neither had they any hieroglyphic or picture writing, or any of the ruder methods of recording events which have prevailed among some nations in the early periods of their history. At the time above mentioned, the English missionaries of the London Missionary Society commenced their labours at the capital, under the auspices of the king, and with all the assistance he was able to afford them. They formed an alphabet, and fixed the orthography for the language, adopting the common European characters to express the native sounds; subsequently they prepared grammars and vocabularies of the language, printed elementary books, and finally translated the Bible into the Malagasy language. Their efforts to teach reading and writing were at first attended with great difficulties, on account of the great aversion of the people to all innovation in their established usages, and from an apprehension of the liberty and safety of their children, as few foreigners, excepting slave-traders, had visited the capital. These difficulties were, however, at length overcome; and during the reign of Radama the schools were not only increased in the capital, but extended to the provinces, and it is estimated that 10,000 or 15,000 scholars were educated. After the death of Radama, the enlightened patron of education among his people, schools and teaching were discouraged, and in a few years entirely prohibited throughout the island. But so self-evident were the advantages and enjoyments of education, and such the earnest desire of those who already possessed them to perpetuate it, that although no public means of education existed, it seems to have been considered as a part of parental duty to educate the children, especially the boys in each family. The degree of proficiency attained by the men and boys belonging to the families of those who had been originally taught in the schools of the mission, shows that great attention and time must have been devoted to their instruction; and although the present government (1857) is not favourable to education, the Hovas, the only portion of the inhabitants among whom it has ever prevailed, seem determined that it shall not be lost, while multitudes of the young are eager for instruction and books. A number of them are very imperfectly acquainted with English; and had the schools continued, many would before this have acquired a degree of proficiency which would have placed within their reach the rich treasures which that language contains. As it is, considering the prohibition of public schools by the government, the amount of education among the Hovas is remarkable. All books treating on the subject of religion being prohibited, and even their possession subjecting to very severe penalties, while few were prepared by the missionaries in which religion was omitted, the people may be said to be almost destitute of books; still, so far as the Hovas are concerned, they are not an uneducated people. The entire Bible, a translation of Bunyan's *Pilgrim's Progress*, and a number of other books of a Christian and educational character exist

Madagas-
car.

in the Malagasy language, together with grammars and dictionaries prepared by the missionaries during their residence upon the island.

The early history of Madagascar is necessarily involved in great obscurity on account of the absence of all records among the people themselves. The name of the island is unknown among the natives, and is only adopted by them as the term by which foreigners designated their country. It was called *Scrandah* by the Moors and Arabs, by whom it was visited for the purposes of trade long before it was discovered by Europeans. The inhabitants of Europe were made acquainted with its existence at the close of the thirteenth century by the publication of the travels of Marco Polo; and it is said to have been discovered by Europeans in the year 1506. By the Portuguese it was called the Island of St Lawrence, probably in honour of the saint on whose day in the calendar it was discovered. The Portuguese formed a settlement on the coast in 1508. By the French, during the reign of Henri IV., it was called *Isle Dauphine*. By Marco Polo it was designated *Magaster*; and by the English it seems always to have been called by the name it now bears. The colony settled by the Portuguese was destroyed by the French, who subsequently formed their first settlement in the island in 1642, by virtue of a patent from Cardinal Richelieu to a Captain Rivault, who, associated with others, formed the French East India Company. It is stated by Flaucourt that at that time the English had a settlement of 200 men at St Augustine's Bay; and it is certain that considerable efforts were in progress for colonizing in Madagascar during the early part of the reign of Charles I., but in the troubles of subsequent periods it appears to have been lost sight of. The French formed settlements at different times, which continued for unequal periods during 100 years, but the last was abandoned about 1740. In the beginning of the present century, and during the administration of General Decaen, the last French governor of Mauritius, French agents were sent to Tamatave and Foulé Pointe to protect the French traders, and facilitate commercial intercourse with the people, who were then regarded as proprietors of the country. These factories, or establishments for the protection of trade, continued till the capture of Mauritius and its dependencies by the English in 1810. On the 17th of February 1811, a British frigate proceeded to Madagascar, and M. Sylvan Roux, the French commander at Tamatave, surrendered to the officers sent down, and the places were occupied by British troops. A settlement was afterwards commenced by the English at Port Loquez, in the north, and a tract of land purchased from the chiefs. But about this time the British government made proposals to Radama, the sovereign of the Hovas, and the most powerful ruler in the island, to abolish the trade in slaves from Madagascar. In 1818 this object was secured by a treaty, and by this treaty the English ceded to Radama all claim to any part of Madagascar derived from the French by conquest, or obtained from the natives by purchase; and Madagascar was declared to be an independent country. The French subsequently claimed certain portions of the eastern coast; but Radama refused to allow their claim, affirming that he alone was sovereign of Madagascar, and they were strangers and foreigners. In 1829 an expedition under M. Gourbeyre was sent, consisting, it is said, of 1500 troops, to take possession of some parts of the coast; and though they succeeded in destroying the village and fort at Tamatave, burning the habitations and killing vast numbers of the people, the resistance they met with at Foulé Pointe obliged them to embark with loss, and finally sail from the coast. No attempt has since been made by the French to obtain possession by force of any portion of the Island of Madagascar; the attack on Tamatave in 1846 being caused altogether by the dif-

ferences between the native rulers and the resident foreign traders.

Madagas-
car.

The reign of Radama, which commenced in 1810, and terminated by his death in 1828, at the early age of thirty-six, was the most important and eventful period in the history of Madagascar. The treaty with England not only secured the abolition of the slave trade, which had become a source of great misery and injury to the people, but was associated with more intimate and friendly relations with that country than had ever existed between the people and any civilized nation; it was followed by the introduction of more honourable commerce and various productions of civilized countries, besides the introduction of European arms and tactics. This last, by rendering other powers subject to the sovereign of the Hovas, united the whole population under one government. A number of youths were sent to Mauritius, and others to England, for education and instruction in the arts of civilized life; and European artisans, sent out by the Missionary Society, introduced several of the most useful handicrafts among the people. Education commenced, and its benefits were widely extended. The power of superstition, so unfavourable to the advancement of the people, was undermined, and its influence, by the shrewdness and address of the sovereign, greatly impaired. Besides the introduction of letters and the useful arts, the missionaries had instructed the people in the Christian religion, and not only was the knowledge of the chief distinguishing truths of Christianity very generally diffused among the inhabitants of the central province, where the missionaries resided, but some few of the people appeared to have adopted in sincerity the faith of their teachers. But on the death of Radama, and the assassination of a number of his friends, including the young Christian prince whom he had nominated as his successor, the party who raised the present queen to supreme power, and administered the government of the kingdom, pursued a course directly opposed to the policy of Radama. Intercourse with Europeans was restricted and avoided, all the innovations of Radama were disapproved, and every effort made to revive ancient usages and the former superstitions of the country. The idols and their keepers were restored to the power and influence they had originally exercised; and it seemed to be the object of the authorities to restore the country to the state in which it was prior to the arrival and instructions of the Europeans, except in regard to the slave trade, which was still forbidden, and the military organization of the forces after the European manner, which was still continued. The benefits of commerce with Europeans were also so obvious and abundant, that efforts were made to preserve and increase them; but beyond this they seemed unwilling to extend their connection with foreigners. Commercial intercourse was, in consequence of the attack of the French and English on Tamatave in 1846, discontinued for several years, and though restored in 1853, the existing authorities have not evinced any desire for more intimate or extended intercourse with Europeans.

The revival of the influence of the ancient superstitions of the country, and other motives, led to the prohibition of religious teaching, and threatened with the severest penalty the profession of the Christian faith, and the practice of any part of Christian worship by any native in Madagascar. The missionaries left the island in 1836; and after this the authorities appear to have determined to use every means in their power to prevent the continuance of Christianity among the people, and a system of persecution, as severe as any through which the disciples of Christ have passed in former ages, was commenced in Madagascar. Multitudes have been sentenced to fines and confiscation, loss of rank and hard labour; others have been sold into irredeemable slavery, or imprisoned in fetters. Some have

Maddaloni died in chains from starvation; others from drinking the poison-water; others have been put to death by spearing or hanging. Some have been burnt alive; others have been thrown from steep rocky precipices, and their mangled remains left a prey for the dogs. Numbers have thus honoured the Christian faith by the blameless consistency of their lives, and the heroic constancy and holy fortitude of their deaths. Christianity, nurtured by the teachings of the few portions of the Bible still existing among them, continues. It is said that the young prince, the queen's only child, and heir-apparent to the throne, is himself a Christian, and has fully and publicly identified himself with the Christians, and afforded them all the protection and encouragement which his rank and influence affords. Though the laws against Christianity are not repealed, there is no active persecution, and none have for several years past been put to death on account of their religion. (w.e.)

MADDALONI, a town of South Italy, kingdom of Naples, and province of Terra-di-Lavoro, 14 miles N.N.E. of Naples. It has several churches and convents, an hospital, and a royal college. It has also some manufactures, and carries on a considerable trade in the products of the vicinity. The noble aqueduct which conveys water to the royal palace of Caserta is conspicuous here. Pop. 12,500.

MADDER. See **DYEING**, c. iv. § 1.

MADEIRAS, ~~THE~~, a group of islands in the North Atlantic Ocean, consisting of two inhabited islands, named Madeira and Porto Santo, and three uninhabited barren rocks, named collectively the Desertas. Funchal, the capital of Madeira, is in N. Lat. 32. 37. 45., and W. Long. 16. 55. 20.

Madeira, the largest of the group, has a length of 30 geographical miles, an extreme breadth of 12 miles, and a coast line of about 72 miles, leaving out of view the indentations, which are not great. Its longer axis lies E. and W.; and it is traversed in the same direction by a mountain chain, having a mean altitude of 4000 feet, and forming the backbone of the island, up to which deep ravines penetrate from both coasts. Pico Ruiwo, the highest summit, stands in the centre of the island, and has a height of 6100 feet. Several of the adjacent summits are very little lower than this. The greatest part of the interior is uninhabited; for the towns, villages, and scattered huts, either lie near the mouths of ravines, or upon the lower slopes that stretch from the mountains towards the coast. The ridges between the ravines terminate in lofty headlands; and nearly the whole coast is bound by precipices of dark basalt or crumbling tufa. On the S. side of the island there is left hardly any of the indigenous wood which once clothed the whole island, and gave it the name it bears; but on the N., some of the valleys are still filled with native trees of fine growth. The eastern extremity is terminated by a long, narrow, and comparatively low promontory of rock, named Point São Lourenço. Here there is a quantity of calcareous sand, with land shells of an extinct species, and calcareous infiltrations simulating the roots and branches of trees. After Funchal, the capital, the principal places of the island are,—Santa Cruz, Machico, Cama de Lobos, Ribeira Brava, Ponta de Sol, Magdalena, and Calheta, on the S. coast; San Vicente, Ponta Delgada, San Jorge, Santa Anna, Fayal, and Porto da Cruz, on the N. coast. All these towns and villages are at the mouths of ravines, except Santa Anna, which is a parish scattered over ground elevated at least 1000 feet above the sea. The N. coast is bound by a loftier wall of rock, and has altogether a wilder aspect than the S. The roads, in a country with a surface so broken as Madeira, must necessarily be bad, and hence, in transporting articles of bulk or weight, the people make use as far as possible of the sea. A great improvement has taken place within the last two or three years in the roads of the interior; but incessant

repairs are required to keep them passable—the heavy rains of winter being very destructive. Those near Funchal are well paved with small pieces of broken basalt. Madeiras.

It has been conjectured, but on insufficient evidence, that the Phœnicians discovered Madeira at a very early period. Pliny tells us of King Juba's geographical investigations, and mentions certain Purple, or Mauritanian Islands, the position of which, with reference to the Fortunate Islands, or the Canaries, might seem to indicate the Madeiras. There is a romantic story, which every historian of the island feels bound to mention, even while he discredits it, to the effect that two lovers, Robert Machim and Anna d'Arfet, fleeing from England to France in 1346, were driven out of their course by a violent storm, and cast on the coast of Madeira at the place subsequently named Machico, in memory of one of them. In 1419 two of the captains of Prince Henry of Portugal were driven by a storm to the island called by them Porto Santo, or Holy Port, in gratitude for their rescue from shipwreck. The next year an expedition was sent out to colonize the island, and Madeira being described, they made for it, and took possession on behalf of the Portuguese crown. Funchal was made a city in 1508, the seat of a bishop in 1514, and of an archbishop in 1539. When the archbishopric of Goa was created in 1547, the chief ecclesiastical dignity of the island was reduced to a bishopric. For the sixty years intervening between 1580 and 1640, Madeira, with Portugal itself, was under Spanish rule. In 1801 British troops arrived to garrison the island, as an attack on the part of France was expected, but they remained only a few months. In 1807 a large body of British troops, commanded by General Beresford, was again landed, and the island continued under the British flag until the peace of 1814. A few years since, Madeira ceased to be a Portuguese colony, being made a province and an integral part of the kingdom, entitled to send deputies to the Cortes assembling at Lisbon.

The inhabitants are of Portuguese descent, with some intermixture of Moorish and Negro blood. The men are of middle stature, well formed, with black hair and eyes. Those of the lower classes are strong, capable of long-continued labour, and industrious as long as they are under the pressure of want, which is but too generally the case. They are sociable and light-hearted, respectful in their behaviour towards their superiors, and polite towards each other. The women, in spite of their fine hair and eyes, are generally plain. The morals of all classes are not very strict, the priests frequently setting a bad example to the community. At the commencement of 1854 there were 991 foundlings in the different places provided for their reception in Madeira. The dress of the peasantry, without being picturesque, is peculiar. Both men and women wear on their heads the *carapuça*, a small cap made of blue cloth, in shape something like a funnel, with the pipe standing upwards. The men have trousers of linen, drawn tight, and terminating at the knees; a coarse shirt enveloping the upper part of their person, covered by a short linen jacket, or, in the town, by a jacket of blue cloth, completes their attire, with the exception of a pair of rough yellow boots. The women's outer garments consist of a gaudily printed calico gown, with a small cape of coarse scarlet or blue woollen cloth. The natives are fond of music, but they possess little skill in singing or playing, except as regards one instrument, the *machete*, a small kind of guitar, struck by the fingers. The mass of the people is entirely uneducated; and even the higher classes, though usually speaking English or French, seem to have little taste for reading or mental improvement. They are indolent, in spite of the fact that they are becoming poorer day by day. The principal business is carried on by British merchants, in whose hands the chief part of the wine trade has been vested. The British consul receives a salary of £300, and is allowed to

Madeiras. engage in trade. The inhabitants of Madeira amounted in 1855 to 102,837 persons. The population has been gradually decreasing for some years, and this decrease may be in part attributed to the stream of emigration which has of late years set in to the British settlements in South America, and in part to the severe pressure which followed the failure of the grape crop. Notwithstanding that, in the ten years ending with 1855, nearly 35,000 persons left the island as emigrants, there is reason to believe that it is still much too densely populated, looking to the small proportion which the cultivable ground bears to the whole, and to the general want of capital.

**Govern-
ment, civil
divisions,
&c.**

The administration of affairs is in the hands of a civil governor appointed by the crown. At the present time (1856) the same person holds this office and that of military commandant. The defence of the island is intrusted to a battalion of infantry of the line, a detachment of artillery, and a militia of nominally 1200 men. The forts along the shore are neglected and falling to ruin. The law of Portugal is administered by two chief judges appointed by the crown, each of whom has a separate division of the island under his jurisdiction, within which he tries both civil and criminal cases, with the assistance of a jury. Minor cases are taken before magistrates elected by the people. For municipal purposes, the island is divided into nine districts, called *concelhos*, each of which has its municipal chamber (the members of which are chosen by the people), whose duty it is to keep the roads properly repaired, cleansed, lighted, &c. The chief police magistrate of each *concelho*, styled *administrador*, is appointed by government. A bishop, with a yearly income of L.533, is at the head of the clergy, his cathedral being at Funchal. There are 49 parishes, each of which has its church and resident priest. Roman Catholicism is the established form of religion, but other religions are tolerated, except as regards the natives. The island sends four representatives (*deputados*) to the Cortes at Lisbon. They are elected by such of the male inhabitants as possess an annual income of 100 dollars. In 1854 the number of children of both sexes receiving instruction at elementary schools supported by private funds was 197; those of both sexes at the public primary schools supported by the municipalities and by government amounted to 2055, and those at private schools of this class numbered 337. At the Lyceum of Funchal, an establishment falling into the class of secondary schools, there are six professors, who are paid by government. In 1854 the pupils at the Lyceum were 121 in number. The total sum expended by the government on schools of all classes in 1854 was about L.1230. This sum covered the salaries of four professors of medicine and surgery attached to the hospital at Funchal, and the cost of the priests' seminario. By law, all children of a certain age should be sent to school, but this regulation is not enforced, so that probably not more than an eighth part of them are actually receiving education.

Trade.

The manufactures of Madeira are insignificant, their chief object being to satisfy some of the simple wants of the poorer classes. Baskets, straw hats, coarse linen and woollen articles, and shoes, are the principal objects. Artificial feathers, flowers, and sweetmeats are made for sale by the nuns. A good deal of needlework embroidery has been executed of late years by the women of Funchal for exportation, and a few fancy articles are made of the fibre of the *Agave Americana*. The bulk of the labouring population is employed in agricultural pursuits. Wine has hitherto been the chief article of export, but this branch of trade will soon cease. The rearing of the cochineal insect has been lately undertaken, in the hopes of its supplying the loss of the grape. Many of the coopers employed during the existence of the wine trade have emigrated; the rest earn a precarious subsistence. The casks they made possessed repute for excellence of construction. The chief

artisans of Funchal at present are boot and shoe makers, cabinetmakers, carpenters, and stone-masons. The number of merchant ships anchoring at Funchal (which is the only foreign port) during 1855 was 242, of which 121 were British, and 91 Portuguese. The chief imports are,—manufactured goods, iron ware, grain, salt, and timber. In 1855, of grain there was imported 195,765 bushels, principally from the neighbouring coast of Africa, and from the Azores. In the same year 27,800 bushels of salt entered. The official returns of the imports of manufactured goods cannot be relied on. The total receipts of the custom-house in 1855 amounted to rather more than L.17,000. There is no bank on the island; the gold and silver coin in circulation is not Portuguese, but British, American, and Spanish. Accounts are made out in *reis*, imaginary coins, 4800 of which are equal by law to the pound sterling. Spanish and American dollars are current, at the value of 1000 reis, or 4s. 2d. British money. Funchal is a coaling station for the British mail steamers from England to Brazil and the African coast, which touch here once a month on their outward voyages, and again on their return. The Portuguese and French steamers to Brazil likewise touch here. Besides these vessels, two English sailing packets are continually plying between London and Madeira, and a Portuguese packet brig to and from Lisbon.

The system of agriculture in Madeira is of a very primitive description, the implements of every kind being extremely rude, and the ignorance of all principles complete. Probably not more than one-half of the island is cultivated. The want of water keeps large tracts in their original state, and a very large part of the remainder is of such a nature as to defy cultivation. An incalculable amount of labour has been expended upon the soil of Madeira: First in the erection of walls, that have been built with the view of preventing the soil being washed from the slopes into the sea by the heavy rains of winter. In this way a great part of the lower and cultivated region is supported, the inclosures being built up one above another in the form of terraces. Secondly, the *levadas*, or water-courses, have cost vast toil. These works are either of masonry, or cut through the solid rock, and the water is thus brought by long winding channels from points high up in the mountains to the region of cultivation, where it is distributed by subordinate channels to the different inclosures, in regular order, according to the rights of their owners. In the absence of irrigation, the island for half the year would be a bare rock. Water in this climate has its value as well as the soil, and the one is made the subject of bargain, and sells just as much as the other. The springs, as might be supposed, are more numerous and copious on the north side of the great central chain of hills than on the south, whilst the demand for water is more urgent on the south than on the north. Attempts have consequently from time to time been made to convey the water by tunnels from one side to the other, but the skill of the engineers has frequently been inadequate to the difficulties, for the bottom of the completed tunnel has been more than once found to slope in the wrong direction. Could the whole of the south side be properly irrigated, the produce of the island would be wonderfully increased. A very large proportion of the land, perhaps as much as four-fifths, is strictly entailed. The removal of this restriction on the sale of land has been frequently agitated, but hitherto without avail. The relations of landlord and tenant are founded upon the old Roman, or what is now known as the *metayer* system. Money rents are unknown; but the gross produce of the land, after deducting the tithe, is equally divided between the owner and the occupier. It is the latter who is at the expense of all improvements, and these are his absolute property, which he can sell to another, without the consent of the landlord, whenever he pleases, and which, if not otherwise dealt with, will descend to his heirs.

Madeiras.

Madeiras.

The landlord, however, has always the right of getting rid of this incumbrance on his estate by paying his tenant the value of the improvements; but as he is usually without capital, this is very seldom done. Hence, the occupier of the land acquires a nearly perfect fixity of tenure. According to the mode of valuation adopted in such cases, the tenant's share of the land may be estimated to be worth at least as much as the landlord's. The tenements are usually very small; and what we call fields are very rarely seen. The cattle are all stall-fed when they are not feeding on the mountains. Horses are never employed for draught, all the labour of that kind being effected by oxen, of which there is an abundant supply. These animals are small, but strong and hardy. Mules and asses are a good deal employed to convey burdens on their backs. Up to the year 1852, the vine, which was introduced soon after the discovery of the island, yielded the chief produce—that which has given Madeira a name all over the world. In that year disease first manifested itself; it stopped the production of wine, and is gradually destroying the plant. The pressure was at first great upon all classes; but liberal subscriptions from abroad in some degree mitigated the distress. Nevertheless, many persons died from sheer want during the first eighteen months, and a large number were induced to leave the island for the British West Indies or South America. The lower classes have now got past the worst; indeed, they are better off now than they were for several years previous to the appearance of the grape disease. The income of the landlords, however, has not increased with the increasing prosperity of the tenants, and many of them have suffered a loss of at least one-half their revenue. The trade of a wine merchant will soon be extinct; for though large stocks had accumulated, owing to the gradually diminishing demand, the continued drain, in the absence of fresh supplies, will exhaust them in a year or two. Taking the average of the ten years ending with 1855, the annual export was about 5000 pipes, each pipe containing 92 imperial gallons. The cultivators of the soil have covered large tracts with sugar-cane, which here succeeds pretty well, though it does not attain the luxuriance of that in the West Indies. The juice is not converted into sugar, but is distilled into a kind of rum, the whole of which is drunk by the lower classes on the island. The cultivation of grain has considerably increased of late years, and the island now produces a much greater proportion of what is required for consumption than formerly. In 1854 the harvest is supposed to have yielded 113,250 bushels of grain, whilst the importations amounted to 216,290 bushels. Several of the merchants are turning their attention to cochineal, which has succeeded well in the Canaries and in Algeria. The vegetables principally cultivated are, —potatoes, sweet potatoes, pumpkins, beans, French beans, onions, cabbages, and the *Arum Colocasia*; the grain chiefly consists of maize, wheat, and barley. A little arrow-root is made. The coffee tree succeeds well in low damp situations, and the produce commands a higher price on the island than Brazilian coffee. The commonest fruits are,—the orange, peach, guava, fig, custard-apple, granadilla, and banana. Apples, pears, cherries, walnuts, and mulberries, succeed better on the hills than near the shore. Various tropical plants have been introduced of late years, such as the mango and pine-apple. There are large chestnut woods at a height of between 2000 and 3000 feet, producing great quantities of fruit, which forms an appreciable item in the sustenance of the people.

Funchal.

Funchal, styled a city, is the chief town of Madeira, and the capital of the archipelago. It is distant about 1164 miles from the Lizard Point in England, and 380 from the coast of Africa. It has a population, including the neighbouring rural parishes, of nearly 29,000 persons, equal to almost one-third of the total population of the island, but probably not many more than half that number live in the

Madeiras.

town itself. It stands on the shore of a shallow bay on the S. coast, backed by an amphitheatre of mountains. In this position it is seen to great advantage. Numerous country-houses, with their gardens, on the neighbouring slopes, give an air of great cheerfulness to a rugged landscape. The height of the mountains immediately behind may be estimated at 4000 feet. The bay is commanded by the cannon of a small fort placed on an insulated rock near the shore, and those of a fort upon an elevation behind the town. There are no facilities for landing either passengers or goods. The anchorage is tolerably good, and vessels in the bay are safe from all winds, except that from the S. When this blows strong, they are obliged to slip their cable and take to the open sea. The chief edifices are,—the churches, none of which deserve much notice, the governor's castle, and the custom-house, a spacious substantial building. The streets are narrow and irregular, but very clean; at night they are lighted with oil lamps. The city contains three public walks planted with trees, some fountains of excellent water, a large poor-house, flat-roofed, a large hospital, and a jail. The dowager Empress of Brazil is now building an hospital for the reception of 24 consumptive patients of Portuguese or Brazilian birth. Interments have ceased to be made in the churches, and now take place in appropriate cemeteries near the town. The houses are usually furnished with an iron balcony at the windows; and the larger houses have a tall turret. The entrances of some of the great houses are striking, from the spacious paved court, or hall, into which the principal staircases descend. The ground storey is usually set apart for shops, stores, &c., and the windows are defended with stout iron bars, giving a prison-like air to the streets. The shop windows, as in Lisbon, present none of the tempting display of those in an English town. Three small streams traverse the town on their way to the sea, and the deep channels along which they run are crossed by bridges. In summer the streams are nearly dried up. Occasionally during winter the waters are swollen by violent rain on the mountains, and a vast quantity of rubbish is brought down, which chokes up the channel, and compels the water to overflow its banks. In this way much damage has been done in a few hours to the houses in the neighbourhood. A very disastrous inundation occurred during the night, in October 1803, after a hot and dry summer. Great damage was done to property, several houses and a church were swept away, and between 300 and 400 persons lost their lives. In October 1842 another flood occasioned immense damage, but no lives were lost. In December 1855 one of the rivers was blocked up by stones brought down from the hills, and the stream rushed into the adjacent houses on each side. A former governor laid the foundation of a museum of natural history, geology, &c.; and the Camara of Funchal has a small collection of books accessible to the public. The Portuguese Club has a large house, containing ball-rooms and a billiard-table, but no library. The room of the Commercial Association is supplied with newspapers. The affairs of the city are managed by the Camara Municipal, a body of persons somewhat like one of our municipal corporations, the chairman of which is named a president. Their income arises from a share of the duty on grain imported, an impost on salt, fresh meat sold in open market, fish taken, and wine, and on licenses for the opening of shops. They expended in 1854–5 about L.3900, principally in lighting and repairing the streets. The leper's hospital, with its 30 inmates, costs them L.290: their schools about L.400. The markets are well supplied with vegetables, but they are not of the first quality. Flesh meat is cheap, and tolerably good, with the exception of the mutton. Fish is abundant and cheap, when fishing is possible, and forms an important item in the sustentation of the islanders. No wheel-carriages are in use; all cartage being effected either on the backs of mules

Madairas. and asses, or by means of a rude sledge drawn by bullocks. A low, covered car, mounted upon a sledge, and drawn by oxen, is generally used in place of the omnibuses and cabs of our cities. The only other means of locomotion are by horses, palanquins, and hammocks. The hammock is a kind of chair suspended from a pole, each extremity of which is borne on a man's shoulder. The second resembles a ship's hammock, and is likewise suspended from a pole. This affords an easy mode of progression on a long journey. The common people are accustomed to carry heavy burdens on the head and shoulders, and resolutely refuse to make use of such innovations as wheel-barrows and trucks.

The only bookseller's shop in Madeira is kept by an Englishman for the benefit of his countrymen. Some of the Portuguese shopkeepers have a few books on their shelves, but they are chiefly almanacs, or works of Roman Catholic devotion. Four newspapers are published weekly in Funchal, the circulation of which is very small.

Attracted thither by the wine trade, many British merchants have taken up their residence at Funchal. The British resident population of Madeira amounted in 1856 to 75 families and 290 persons. They have built a church and constructed a cemetery. It has its shopkeepers, physicians, and a chaplain, who receives £400 a-year, partly from the residents, and partly from the British government. There are two places of worship where the forms of the English Established Church are used, and the Scotch Presbyterians have likewise a place of religious meeting. Visitors to the number of about 300 annually betake themselves to Funchal during the winter and spring, the major part of whom are persons afflicted with pulmonary disease. The town is entirely protected from the north wind; and though the climate is rather damp, the temperature is remarkably equable. The air is free from dust and smoke; and the trying winds of spring, so prevalent on the continent of Europe, are not felt here. The hotels and boarding-houses are numerous and well conducted, being chiefly in the hands of English persons. Invalids may obtain in most of these very comfortable accommodation. Furnished houses, with gardens, in the immediate neighbourhood of the town, can also be obtained. Good drugs are dispensed by the apothecaries; and most of the articles a temporary sojourner is likely to require may be purchased at the shops. At the English Club there is a billiard-table and a library of 2300 volumes. Such is the number of British assembled every winter in a small space, that a stranger will probably feel his separation from home less here than anywhere else out of England.¹

Climate.

Situate in the temperate zone, about ten degrees N. of the tropics, and surrounded by the ocean, Madeira enjoys a climate of singular mildness; for not only is the winter warm, but the summer is cool. The mean annual temperature of Funchal is about 66° F. In winter the thermometer has never been known to fall lower than 46°·5, and indeed it very seldom touches 48°; whilst the temperature in the summer rarely rises higher than 80° near the shore. The mean temperature of the seasons is nearly the following,—spring, 66°; summer, 70°·5; autumn, 67°·5; winter, 61°. The mean daily range is about 10°. The number of days in the year on which rain has been observed to fall varies from 66 (1850) to 113 (1852); but 88 may be considered the mean. The annual quantity of rain likewise varies considerably; in 1825 as little as 20·43 inches fell, in 1826 as much as 43·35 inches; but 30 inches may be considered the average fall, and of this quantity nearly $\frac{2}{3}$ ths fall in winter, $\frac{1}{3}$ th in autumn, and $\frac{1}{6}$ th in spring. A heavy and prolonged descent of rain usually occurs in September or October, after which the weather clears up until Janu-

ary. Rain continues to fall, at more or less distant intervals, until June, after which come months of settled weather, almost unbroken by a shower. The rain is often very irregularly distributed through the colder months. At the commencement of the rainy weather, and sometimes in the course of the winter, the rain falls with almost tropical violence. Observations with the wet and dry bulb thermometer four times daily through the first four months of 1852 and 1853, gave, as a mean result, 73 per cent. of the vapour required for the saturation of the atmosphere. Observations taken eight times daily in the seven months from November 1854 to May 1855, yielded results that showed the air held 71·6 per cent. of the vapour necessary for saturation. It must be remembered that Madeira is a small island in a warm latitude, and that the air must consequently contain a considerable quantity of aqueous vapour from the proximity of the sea. The prevalent winds are those that blow from the N., or from a point or two E. or W. of N. The W. wind, coming across a great expanse of ocean, brings rain; that from the E., coming from Africa, is a dry wind. The *leste* of the inhabitants is a hot and dry E.S.E. wind, which visits Madeira for a few days each year, usually in the summer. It has been compared to the *scirocco* of southern Europe, but it has few of the disagreeable effects of that wind; and some persons even feel an unusual exhilaration of spirits during its continuance. The mountain-tops are then hotter than the lower regions, but even there the thermometer sometimes indicates 98°; and, at a much lower temperature than this, furniture, books, &c., show the extreme dryness of the air by bending or cracking. As the thermometer never approaches the freezing point by several degrees, frost and snow are wholly unknown in Funchal; but snow falls on the mountains at least once during the winter, not lower, however, than 2500 feet above the level of the sea; and hail sometimes makes its appearance in the storms of wind which occasionally burst over Funchal. A series of daily barometrical observations, made at ten A.M. for six years, at a locality 89 feet above the sea, gave 30 inches as the mean annual reading. Sir James Clark, speaking of the climate of Madeira with reference to its effects on pulmonary disease, makes the following remarks:—"When we take into consideration the mildness of the winter and the coolness of the summer, together with the remarkable equality of the temperature during the day and night, as well as throughout the year, we may safely conclude that the climate of Madeira is the finest in the northern hemisphere. That great and lasting benefit is to be derived (by an invalid) from a temporary residence in the climate of Madeira many living examples sufficiently prove."

The *Desertas* are three long, narrow rocks (one of them attaining the height of 2000 feet), lying at the distance of about 11 miles S.E. from the nearest part of Madeira. They present nearly vertical precipices to the sea on both sides, and are not easily accessible; yet persons visit them for the purpose of sowing a little grain and gathering the scanty crop. Rabbits and gulls are abundant, and there are seals at one of these islets.

Porto Santo, where a lieutenant-governor resides, lies about 25 geographical miles N.E. of Madeira, surrounded by several uninhabited islands and rocks. Its length is about $6\frac{1}{2}$ geographical miles, and its greatest breadth 3 geographical miles. Its population, according to the return of 1854, amounted to 1708 persons. The only town bears the name of the island, which is unproductive, the supply of water being scanty, and bare of every kind of wood. Before the grape disease made its appearance, 1500 pipes of wine of an inferior quality were annually made here, which was distilled into brandy, for the purpose of mixing

¹ Further information respecting the island will be found in a little work entitled *Madaira, its Climate and Scenery; a Handbook for Invalids and other Visitors*, 2d. ed., Edin. 1857.

Madeiras.

with the wines of Madeira. Around the town there is a large tract of comparatively level ground, great part of which is covered by calcareous sand (perhaps an ancient sand-dune) containing fossil land-shells. At the extremities of the island are hills, of which Pico de Facho, the highest, attains the altitude of 1660 feet. Small sailing boats are continually passing between Porto Santo and Madeira to convey to the former the various requirements of the inhabitants, including firewood, and the greater part of their food. Hardly any grain, besides barley, is cultivated.

Zoology.

Madeira has no indigenous land mammals. The wild goats and swine, spoken of by some of the early voyagers, must have escaped from confinement. The rabbit, which abounds in certain parts of the island, and at the Desertas, the black rat, brown rat, and mouse, have all been introduced. Seals, however, were encountered by the first comers, and this amphibious animal still haunts the Desertas. The porpoise is occasionally seen swimming near the shore.

As to birds, it appears that only one is peculiar, and that is a wren. Amongst the thirty species which breed on these islands are,—the kestrel, buzzard, and barn-owl; the blackbird, redbreast, blackcap, wagtail, goldfinch, two swifts, three pigeons, the quail, red-legged partridge, woodcock, two petrels, and three puffins. The green canary, the ancestor of our domesticated bird, is abundant here, as well as in the Canary Islands. About seventy other species have been occasionally seen at Madeira, straggling thither chiefly from the African coast, and many of them coming with the *leste*. The commonest of these are the sparrow-hawk, two herons, the common curlew, snipe, coot, water-hen, widgeon, kittiwake, and hoopoe. Sometimes the Egyptian vulture, the solan goose, the common starling, thrush, wren, skylark, sparrow, martin, turtle-dove, bittern, corn-crake, cuckoo, and crow, find their way thither, as well as the African bee-eater and the European goat-sucker.

The reptiles are very few, and none are poisonous. A small lizard (*Lacerta Dugèsii*) is abundant, and makes its appearance in thousands on a sunny wall. It was very destructive to the grape crop. A frog has been introduced, and is gradually making its way over the island. A turtle (*Cauwana caretta*, J. E. Gray) is frequently captured, and cooked for the table; but the soup is much inferior to that made from the green turtle of the West Indies.

The fishes are said to belong to nearly 190 species, many of which are peculiar, and beautiful or curious. Several of them are used for food, and amongst these are the tunny, which is sometimes taken of the weight of 300 lb., Jew-fish, mackerel, John Dory, grey mullet, red mullet, and braize. Amongst the more curious may be mentioned several species of shark, the torpedo, the stag-horned horse-fish, the striped remora, flying-fish, sword-fish, and trumpet-fish.

Nearly 1200 species of insects have been found at the Madeiras, and of these the beetles claim 555 species, the Hymenoptera about 217 species, and the Diptera about 160 species. The beetles have been described in Mr Wollaston's elaborate volume, *Insecta Maderensia*; but none of the other orders have yet received a close examination. Gay colours are rare in the Madeira Coleoptera, the tints being usually obscure. The type of this section of the fauna is, in the main, Mediterranean; and it is said to have a greater affinity to the fauna of Sicily than to that of any other country which has been hitherto investigated. One or two of the spiders are reputed to be poisonous.

About 119 species of shells, covering land molluscs, exist at the Madeiras, of which 111 are peculiar, and of the whole number, 76 belong to the genus *Helix*. In addition to the above, 13 species of dead land shells have been

found in calcareous sand-beds, which do not correspond to living species.

Madeiras.

A list, acknowledged to be incomplete, of 156 species of marine testaceous mollusca, found at Madeira, has been printed; 70 per cent. of the species being common to the Mediterranean and the Lusitanian coast, and 45 per cent. common to the coast of Britain. The corals are very few, but there are many kinds of sponge; none, however, of any value commercially.

A considerable number of the plants found in the lowest Botany.

regions have certainly been introduced since the colonization of the island by the Portuguese. Besides these, a large portion of the flora is of a Mediterranean character. Of the rest, the great majority is common to Madeira and the Canary Islands; but there still remain between 80 and 90 plants which are peculiar. The flowering plants, found truly wild, belong to about 364 genera and 650 species: the monocotyledons numbering 72 genera and 122 species; the dicotyledons 292 genera and 528 species. The proportion of monocotyledons to dicotyledons is therefore 10 to 43. The three largest orders are—Compositæ, Leguminosæ, and Graminaceæ. Madeira contains 41 species of ferns, 3 of which are peculiar to it, and 6 others belong to the peculiar flora of the islands of the North Atlantic. A connection with the flora of Madeira and that of the West Indies and tropical America has been inferred by the presence in the former of 6 ferns, found nowhere on the continent of Europe or in North Africa, but existing on the islands of the E. coast of the American continent, or on the Isthmus of Panama. A further relationship to that continent is to be traced by the presence in Madeira of the beautiful shrub *Clethra arborea*, Ait., belonging to a genus which is otherwise wholly American. In the lower regions the dragon-tree (*Dracæna Draco*, L.), and a cactus (*Opuntia Tuna*, Willd.) are forms more striking to the eye than any other amongst the indigenous vegetation. Of the former, very few wild specimens remain; but the Cactus exists in such abundance in the lower regions, as to give a character to the landscape. Amongst the trees, four of the laurel order are most conspicuous. The other trees most worthy of note are,—a *Pittosporum*, a *Heberdonia*, a *Juniperus*, a *Sideroxylon*, a *Rhamnus*, and an *Olca* (*Picconia*),—all now more or less scarce. The juniper attains a height of 40 or 50 feet, and yields a scented wood, which is prized by the cabinetmaker. Two heaths of arborescent growth, and a whortleberry, cover large tracts on the mountains. The flora of Madeira has been greatly defaced by the reckless hand of man. Several of the trees and shrubs grow only in situations that are nearly inaccessible; and some of the plants are of the greatest rarity. Few specimens of the noble forests that once clothed the island remain, and these are daily decreasing. The coast is too steep, and the sea too boisterous, for a luxuriant marine vegetation. Between high and low water mark there is a narrow fringe of *Ulvæ*, with a few small plants belonging to the orders *Fucaceæ* and *Ceramiceæ*.

Nearly the whole of Madeira is of volcanic origin. The Geology.

foundation of the island may have been either laid under the sea, or pushed through the floor of a continent; and two distinct causes, operating in some degree contemporaneously, have contributed to its present elevation. First, a long and complicated series of eruptions gradually piled up a mass of basalt, tuff, clinders, ashes, &c., to the height of between 4000 and 5000 feet; secondly, this mass, or so much of it as was then in existence, was upheaved to the extent of from 1000 to 2000 feet. Evidence that at least part of Madeira is of submarine origin is afforded by fragments of limestone imbedded in basalt and tuff, in a valley near the northern coast. Although the structure of the limestone has been much changed by heat, the genera of

Madeiras. its marine shells can still be identified. But it seems to be only the nucleus of the island that yields any trace of a submarine origin; the upper two-thirds at the centre, and all the exterior beds downward to the coast, are apparently of supra-marine formation. That there were pauses of considerable duration in the accumulation of the materials of the island, is shown by several facts. The lignite and leaf bed of San Jorge, lying under 1200 feet of lavas, prove that time was allowed for the growth of a vegetation of a high order. It is clear, moreover, that great alterations and dislocations had taken place in the rocks of various localities before other lavas and tuffs were in existence.

There do not appear to be any data for determining when volcanic action first commenced in this locality; but the limestone fossils, though scanty, afford evidence that the upheaval of that portion of the island at least took place during, or subsequent to, the miocene tertiary epoch. Nor is anything clear as to the period of the cessation of volcanic action. At the present day the subterranean fires seem perfectly extinct. There are no live craters, nor smoking crevices, as at the Canaries and Cape Verdes; or hot springs, as at the Azores. On the slopes which descend from the central ridge to the sea, especially in the neighbourhood of Funchal, there are many hills with conical shapes of more or less regularity, which seem to have been formed at a comparatively modern epoch. Volcanic cinders and slag are lying upon several of them, which look as if they had been thrown out of a furnace yesterday. Yet, round the base of others there may be traced streams of lava flowing from a higher source, and showing that, subsequent to the construction of these lateral cones, modern as they look, molten matter issued from higher vents, which assumed, on cooling, the character of ordinary compact basalt.

If we examine the general configuration of Madeira, we shall see a mountain chain, about 30 miles in length, running E. and W., and throwing off lateral ridges, that give it an extreme breadth of about 12 miles. Peaks rise about the middle to a height of more than 6000 feet; and deep ravines, lying between the lateral ridges, strike for the most part N. and S. from the central ridge to the sea. In the sections afforded by the ravines, the nucleus of the island is seen to consist of a confused mass of more or less stratified rock, upon which rest beds of tuff, scorizæ, and lava, in the shape of basalt, trap, and trachyte, the whole traversed by dykes. These beds are thinnest near the central axis; as they approach the coast they become thicker and less intersected by dykes. They do not often exceed 1500 feet in thickness, but a section in the Curral shows that they have there a thickness of 3000 feet. Near the axis their angles vary from 3° to 7°; but 2 or 3 miles away they are inclined at angles of 10°, 13°, and even 20°. Sir Charles Lyell is of opinion that these lavas issued, for the most part, from vents situate in the central district; that the form originally possessed by the whole island was that of a flattened dome, with sides varying in their slope from 3° to 7° or 8°; and that the present steeper inclination of the lava was acquired at a subsequent period, when shaken by convulsions which attended eruptions from lateral vents, whether clefts or craters, at a much lower elevation. At the centre of the island there are several summits of nearly the same altitude, and these are in some places connected by narrow walls and ridges, which are frequently quite impassable, whilst at others they are separated by ravines of enormous depth. On all sides are seen vertical dykes, projecting like turrets above the weathered surface of the softer beds. Sir C. Lyell found the materials of many of these peaks arranged with a quaquaversal dip, and he therefore considers them to be the ruins or skeletons of cones of eruption.

In the various parts of the island may be seen elevated
VOL. XIII.

tracts of comparatively level ground. These are supposed to have been formed by the meeting of numerous streams of lava flowing from cones and points of eruption in close proximity; various ejections assisting at the same time to fill up inequalities. Deep down in the lateral ravines, covered by beds of basalt, there exist cones of eruption which have been overwhelmed by streams of melted matter issuing from the central region, and afterwards exposed to view by the same causes that excavated the ravines. These ravines may be regarded as having been formed at first by subterranean movements, both gradual and violent, which dislocated the rocks, and cut channels along which streams flowed to the sea. In course of time the waters, periodically swollen by melted snows and the copious rains of winter, would cut deeper and deeper into the heart of the mountains, and would undermine the lateral cliffs, until the valleys became as wide as we now find them. Even the Curral, which, from its position in the centre of the island, its rounded shape, and other circumstances, has been usually deemed the ruins of a crater, is thought to be nothing more than a valley scooped out in the way described. The rarity of crateriform cavities in Madeira is very remarkable. There exists, however, to the E. of Funchal, on a tract 2500 feet high, the Lagoa, a nearly perfect crater, 500 feet in diameter, and with a depth of 150 feet; and there is another equally perfect in the district known as Fanal, in the N.W. of Madeira, nearly 5000 feet above the sea. The basalt, of which much of the upper part of the island is composed, is of a dark colour and a tough texture. It is sometimes full of vesicular cavities, formed by the expansion of imprisoned gases. Olivine and augite are frequently disseminated in it. A rudely-columnar structure is very often seen in the basalt, but there is nothing so perfect as Staffa or the Giant's Causeway. The trachytic rocks are small in quantity compared with those of the basaltic class. The tufa is soft and friable, and generally of a yellow colour; where a hot stream of lava has been poured over the tufa, it has assumed a red colour. Black ashes and fragments of pumice are sometimes found in the tuffaceous strata.

The mineral contents of the rocks of Madeira are unimportant. There are no metallic mines; a small quantity of native lead has, however, been found. The lignite is too impure to be of any value as fuel. No sulphur has been found; but a little iron pyrites and specular iron are occasionally met with. The mineral spring of St Antonio, near Funchal, is impregnated with carbonate of iron, and small quantities of the muriates of soda and magnesia, but no sulphates have been detected in it. The basalt yields an excellent building-stone, various qualities of which are quarried near Cama dos Lobos, 5 or 6 miles W. of Funchal. A small quantity of sienitic greenstone has been discovered, *in situ*, near Porto da Cruz, evidently pushed up from below.

At Porto Santo the trachytic rocks bear a much greater proportion to the basaltic than in Madeira. An adjacent islet is formed of tuffs and calcareous rock, indicating a submarine origin, upon which supra-marine lavas have been poured. The older series contains corals and shells (also of the miocene tertiary epoch), with water-worn pebbles, cemented together by carbonate of lime; the whole appearing to have been formed upon an ancient beach. The calcareous rock is taken in large quantities to Funchal, to be burnt into lime for building purposes.

Some philosophers have thought that many of the facts regarding the fauna and flora of the Atlantic islands may be explained by supposing that there existed, at a geologically modern period, a large tract of land which connected these islands with the continents of Europe and Africa. (J. R. J.)

MADEIRA, a river of South America, Brazil, formed by the junction of the Beni and Mamore, in S. Lat. 10. 23., W.

Madison, James
 ||
 Madison.

Long. 65°, and falling into the Amazon after a N.E. course of about 700 miles.

MADISON, JAMES, fourth president of the United States of America, was born in Virginia in 1758. He was educated at the college of Princeton, in New Jersey, where he graduated in 1772, and commenced to prepare himself for the bar. He began his political career in 1776 as a member of the Virginia Convention, when he gave early proof of high talent and patriotic zeal. He took his seat as a member of Congress in 1780. After the settlement of the dispute between Great Britain and the colonies, Madison returned to private life, to prosecute his legal studies and extend his acquaintance with natural history, his favourite branch of science. He was again elected to the Virginia legislature in 1784, when he planned and took an active part in completing the constitution of the United States. His personal record of the debates of the convention respecting the constitution is the only complete or authentic information on that subject extant. He was chosen a member of the first Congress under the constitution in 1789, when he gained the friendship and esteem of General Washington and other eminent men of his time. When Jefferson was elected president, he became his secretary of state, and took an active part in the negotiations then pending between the United States and Spain, Britain, and France. His *Examination of the Doctrines of National Law* is said to be one of the ablest papers on the relative rights of neutral and belligerent powers to be met with. He succeeded Jefferson as president in 1809; and one of his first acts was to forbid all communication with England and France till those powers should revoke their orders in council and their Berlin decrees. France complied, but England stood firm, and this induced a five years' war between the United States and Britain. Notwithstanding the misfortunes of this war, and the active opposition of the federalists, Madison retained the presidency till 1817, when, peace being concluded with Britain, he retired from office with a high reputation for eminent ability and spotless integrity. With the exception of occasional assistance given to the legislature of Virginia in revising their constitution, and the discharge of the duties of rector of their university, Madison remained in the closest retirement till his death in 1836, at the advanced age of eighty-five. His debates, letters, papers, essays, and miscellanies, were purchased by Congress for 30,000 dollars, and published in 3 vols. large 8vo, under the editorial superintendence of H. D. Gilpin, in 1840.

MADISON, a city of the United States of North America, capital of the state of Wisconsin, Dane county, on an isthmus between Third and Fourth Lakes, 80 miles W. of Milwaukee. The land on which it stands rises abruptly from the lakes; and has a generally unequal surface, commanding, however, a most extensive and charming prospect. The capitol, built of limestone, is situate on a platform 70 feet above the lakes; and to the W. of this, on an eminence nearly 60 feet higher, stands the Wisconsin university, founded in 1851. Iron and wool are manufactured here, and a brisk trade is carried on in agricultural produce. Water power is abundant; and by railway the town is connected with the Mississippi and Lake Michigan. Pop. (1850) 1525, (1855) 8664.

MADISON, a town and river-port of the United States of North America, capital of Jefferson county, Indiana, on the right bank of the Ohio, 86 miles S.S.E. of Indianapolis. It is beautifully situate in a valley nearly 3 miles long, and inclosed on the N. by steep and rugged hills. The streets are well built, and the houses are mostly of brick. Its chief edifices are,—a court-house, a gaol, two market-houses, and several large schools. The inhabitants are principally employed in manufacturing cotton, wool, iron, and oil. Steamers from this port communicate regularly with the

Mississippi throughout the year, navigation being usually open here all winter. Madison was settled in 1808. Pop. (1850) 8681, (1853) about 12,000.

MADRAS, a city of Hindustan, and the capital and seat of government of the presidency of the same name, is situate on the coast of Coromandel, on the western shore of the Bay of Bengal. The English possessed no fixed establishment here until A.D. 1639, when they received a grant from the Hindu dynasty of Bijanagur, then reigning at Chandergherry, permitting the erection of a fort. In consequence of this permission, Mr Day, the chief of the factory at Armegon, proceeded with great alacrity to the construction of a fortress, which was soon surrounded by a town; and this town he allowed to retain its Indian appellation, but the fort he named Fort George. The territory granted along with it extended 5 miles along the shore, and 1 mile inland. The fort is an irregular polygon, somewhat in the form of a semicircle, of which the sea-face is nearly a diameter, and presenting a front on that side of 500 yards. Towards the land, the fort presents a double line of fortifications, both bomb-proof. The sea-face is armed with heavy guns. Within the inclosure are the barracks, which are said to be capable of affording accommodation for 1000 men. Attached to the barracks is a bazaar for the supply of the troops; the other buildings within the fort are,—the old church, the exchange, and various government offices. A wide esplanade separates the fort from the Black Town of Madras. The latter is inhabited chiefly by natives. There are three broad streets running N. and S., and dividing the town into four nearly equal parts. These streets are well built, and contain many houses with upper storeys and terraced roofs. On the beach, parallel with these streets, is a line of public offices, including the supreme court, the Marine Board office, the custom-house, and the offices and storerooms of the principal European merchants. These are well finished buildings. In conspicuous situations in the town are the male and female orphan schools. The other buildings of note are,—the gaol of the supreme court, the mint, the Roman Catholic cathedral, the Church Mission chapel, the Armenian church, Trinity chapel, the general hospital, and medical school. Various suburbs, or divisions, have gradually grown up around the old town and are now included within the city. These are Royapooram, on the N. of the Black Town; Vepery, including Pursewakum, situate to the W.; Chintadrappettah, separated from Vepery by the River Koom; Poodoopetta and Egmore, lying W. of Chintadrappettah; and Triplicane with St Thome, situate to the S. of the fort. The accession of these divisions has imparted an irregular shape to the city of Madras, the circumference of which is stated to be about 12 miles. The population has been estimated at 720,000. Triplicane is divided from the fort by the River Koom. About a mile from its mouth, this river divaricates, forming two nearly equal branches, the left, or more northern of which flows by the fort, while the right takes a direction first S., and subsequently S.E. The two branches meet each other about 300 yards from the sea, and inclose an island three-quarters of a mile in length, and of half that in breadth, laid out with roads, and ornamented in the centre by a statue of Sir Thomas Munro. On the bank of the right branch of the river are the government gardens. Government House is large and handsome; the floors, the walls, and the pillars, are of the most beautiful chunam of different colours, almost equal in splendour to marble itself. The roads are a great ornament to the place, being broad, and shaded on each side by a noble avenue of trees. Chepak Garden, the residence of the last Nawab of the Carnatic, is situate S.E. of Government Garden; and between it and the sea is a mosque of some architectural excellence, the only Mussulman place of worship of any importance in the city. The principal church belonging to the English establishment is that of St

Madras.

Madras. George, situate in Royapetta. It is said to be very beautiful. St Andrew's church, built for the use of the members of the Church of Scotland, is in the southern part of the Vepery division. It has been regarded as a fine specimen of architecture and engineering skill; but Bishop Heber thought the form injudicious with a view to hearing. It was finished in 1820, at a cost of about L.20,000. The European residents live in garden-houses, or villas, situate in compounds, or distinct inclosures, dispersed throughout the suburbs, and about the neighbourhood of the city, extending from 3 to 4 miles inland. These are generally of two storeys, constructed in a pleasing light style of architecture, terraced with porticos and verandahs supported by pillars.

In Lord Valentia's account of Madras, it is observed, that it would probably have been difficult to find a worse place for a capital than that chosen for Madras, on the extreme point of a coast where the current is most rapid, and where a tremendous surf breaks even in the finest weather. But the original error of fixing on this for the site of a great capital cannot now be recalled, the expense of removal to a more convenient spot would be so great. Owing to the exposed situation of Madras, it affords no secure anchorage; and there is always a great difficulty in landing from vessels, which generally moor in 9 fathoms, with the flag-staff W.N.W., about 2 miles from the shore. Any ship's boat that should attempt to cross the surf would inevitably perish; and, accordingly, the boats from ships anchor outside the broken wafer, and wait for the country boats to carry the passengers safely to the shore. These boats are of a particular construction, being built of soft wood, with flat bottoms. They are sewed together, and have not a nail in their whole construction, so that they are very light and pliable, and are borne many yards through the surf without injury, as they yield to the waves like leather. These boats require to be guided by seamen of experience and tried skill; and it is an extremely critical operation to conduct them through the surf. When they come within its influence, the cockswain stands up, and, under great agitation, marks time with his voice and his foot, whilst the rowers work their oars backwards until overtaken by the swell, which, curling up in its approach to the shore, sweeps the boat along with fearful violence. The rowers now ply every oar forward with their utmost vigour, to prevent the wave from carrying back the boat with its receding swell; and by a few successive surfs the boat is at length dashed high and dry on the shore. A species of floating machine, called a *catamaran*, formed of two or three light logs of wood, 8 or 10 feet in length, lashed together with a small piece of wood inserted between them, to serve as a stem-piece, is employed by the fishermen and lower classes of natives to carry them through the breakers. On these they go out to fish, or to carry letters, or small quantities of refreshments to ships, when no boats can venture out. They secure the letters in a pointed cap, where they cannot be damaged; and when the men happen to be washed off by the surf, they regain the catamarans by swimming, unless when they are attacked by a shark. The dexterous navigators of these frail vessels, who distinguish themselves by saving persons in danger, or by their care in conveying papers through the surf in dangerous weather, are rewarded with medals. European passengers, when they land at Madras, being ignorant of the language, manners, and customs of the country, necessarily rely on the natives for help; and accordingly passengers landing at Madras are immediately surrounded by numerous servants of all kinds, called *dobashies*, eager for employment. They undertake to transact for the Europeans all their necessary business, to buy all that is wanted, and to procure servants, tradesmen, palanquins, and the like.

Madras, when seen from the sea, presents a striking appearance, the fortifications of Fort St George being within

a few yards of the shore; and, at a distance, minarets and pagodas are seen mixed with trees and gardens. The public offices and storehouses are fine buildings, with colonnades to the upper storeys, supported on arched bases, covered with beautiful shell-mortar from Madras, which is hard, smooth, and polished. These being near the beach, which is always crowded, form interesting objects. At a distance, the low, flat, sandy shores extending to the N. and S., and the small hills that are seen inland, give an appearance of barrenness, which, however, improves on a closer inspection. Madras is surrounded by a level country, which in general exhibits a naked, brown, dusty plain, with few villages to enliven the scene, or any other objects to relieve the eye, except a range of abrupt detached hills to the S. The huts of the natives are covered with tiles, and are fully superior in their appearance to those in Bengal; and in the inns and choultries, also, which are common on the roads, travellers experience greater attention.

Madras being the seat of the government of the presidency, the governor, members of council, and public functionaries reside here, as do also the judges of the supreme court. The chief establishments of every department of the government are here, and there are various local establishments. Among these may be mentioned the police-office, the court for the recovery of small debts, the government savings-bank, the bank of Madras, and various insurance offices. Madras is the seat of an episcopal see. In addition to the principal church (St George's) there are about eight English churches and chapels of the United Church of England and Ireland. In the Scottish church of St Andrew, already mentioned, the worship is conducted by ministers in communion with the Established Church or Scotland, of whom two are chaplains in the service of the Company. The seceding body from the Established Scottish Church, calling itself the "Free Protestant Church of Scotland," maintain public worship in the hall of the Free Church Mission Institution. The Romanists have a bishop, or vicar-apostolic. The Wesleyans have five chapels, the Baptists two, the Independents one, and the American Mission two. Measures have been recently taken for the introduction of a new scheme of state education throughout India, in the benefits of which the city of Madras will largely participate. There is an agricultural and horticultural society, of which the governor is the patron. The Madras Literary Society enjoys the same distinguished patronage, and now adds to its title that of the "Auxiliary of the Royal Asiatic Society." About nine or ten newspapers are published at Madras, some of these three times a week, some twice, and some once only.

In 1744 Madras was besieged by the French from the Mauritius under M. de la Bourdonnais. The town was taken on the 10th of September, and was ransomed for L.440,000, exclusive of plunder, which amounted to L.200,000 more. All the British inhabitants were afterwards compelled to abandon the place. Madras was restored at the peace of Aix-la-Chapelle, and evacuated by the French in August 1749, when it was found in a very improved condition, the bastions and batteries having been greatly enlarged and strengthened. The defences of the town were still, however, inferior to those of Fort St. David, where the East India Company ordered the presidency to continue. Madras was again besieged in 1758 by the French under M. Lally. The siege commenced on the 17th of December, and was prosecuted with vigour till the 17th of February 1759, when the French were obliged precipitately to raise it. This was the last and most memorable siege which Madras ever sustained. The garrison consisted of 1758 European troops, 2200 Sepoys, and 150 European inhabitants. The besieging force consisted of 3500 Europeans, 2000 Sepoys, and 2000 native and European cavalry. Since this period Madras has never been assailed by an enemy, though nearly

Madras.

Madrid. approached by Hyder's cavalry in 1781, when they descended from the mountains to ravage the plains of the Carnatic. The population of the city of Madras, including the suburbs, has been estimated, as above observed, at 720,000. Lat. 13. 5., Long. 80. 21.

The presidency of Fort George, or of Madras, comprehends nearly the whole of India S. of the Krishna River, and also that large portion of the Deccan, the Northern Circars. Within these boundaries there are several native states. The rest of the country is under the immediate jurisdiction of the governor and council of Madras, and, for the collection of the revenue and the administration of justice, is divided into districts. The names of these, with their respective areas and amount of population, are set forth in the following tabular statement:—

Districts.	Area in Square Miles.	Population.
Rajahmundry.....	4,501	1,012,036
Masulipatam.....	4,711	520,860
Guntoor, including Palnaud.....	4,752	570,089
Nellore.....	7,959	935,690
Chingleput.....	2,717	583,462
Madras, City of.....	27	720,000
Arcot, south division, including Cuddalore...	5,020	1,006,005
Arcot, north division, including Consoddy...	6,580	1,485,873
Bellary.....	12,101	1,229,599
Cuddapah, including Poonganoo.....	13,298	1,451,921
Salem, including Vomundoor and Mulla-		
pandy.....	7,499	1,195,377
Coimbatore.....	8,151	1,153,862
Trichinopoly.....	2,922	709,196
Tanjore, including Najore.....	3,781	1,676,086
Madura, including Shevagunga and Ramnad	13,545	1,756,791
Tinnevely.....	5,482	1,269,216
Malabar.....	6,050	1,514,909
Canara.....	7,152	1,056,333
	116,248	19,847,305
Ganjam.....	5,758	926,930
Vizagapatam.....	4,690	1,254,272
Kurnool.....	3,278	273,190
Coorg.....	2,116	Not known.
Total.....	132,090	22,301,697

The native states of Travancore and Cochin, and the hill zemindaries adjoining the British district of Vizagapatam are also under political and military management of this presidency. Mysore, though under the political management of the government of India, is subject, for all military purposes, to the jurisdiction of the Madras presidency, by the territories of which it is indeed almost completely surrounded. Their respective areas are stated as follows:—

	Square Miles.	Population.
Cochin.....	1,988	288,176
Mysore.....	30,886	3,460,696
Poodocottah (Rajah Tondiman's dominions)...	1,165	61,745
Travancore.....	4,722	1,011,824
Jeypoor and hill zemindars.....	13,041	391,230
Total.....	51,802	5,213,671

And if to these aggregates be added the area and population of the territory of the Company in this presidency, the total area will amount to 183,892 square miles, and the total population to 27,515,368.

(Further particulars connected with the Madras presidency will be found under the article HINDUSTAN, and also under the names of the various provinces and districts into which the presidency is divided.) (E. T.)

MADRID, a province of Spain, one of the five into which New Castile is divided, lies between N. Lat. 39. 53. and 41. 7., W. Long. 3. 10. and 4. 35. It is divided into thirteen *pañidos*, containing 225 *pueblos*, with a population in 1849 of 405,737, in a space of about 1310 square miles. It is separated from the province of Guadalajara by the Somosierra, and from Segovia by the Carpetanos and the Sierra

Guadarrama, whose ramifications form the principal mountains of the province. It lies in the basin of the Tagus, which, rising in the province of Cuenca, arrives in that of Madrid after a course of 20 leagues, and leaves it after a tortuous course of about 18, having received the Jarama, and some less important streams. Other rivers in this province are the Lozoya, the Guadarrama, the Manzanares, the Tajuña, and the Henares. The soil is mostly clayey, and there are sandy tracts. Agriculture is in a backward and neglected condition. The productions consist of wheat, barley, rye, oats, algarrobas (a kind of pulse), pease, French beans, and other legumes; wine, oil, flax, hemp, fruits, wax, honey, &c. Gardening is carried on to some extent near the capital, though the markets of Madrid receive their most liberal supply of fruits and vegetables from Valencia. Sheep, goats, and horned cattle are reared; and fish are found in the Jarama and other rivers. In the Sierra Guadarrama are quarries of granite, lime, and gypsum. There are mines of lead, iron, and copper in the same sierra, and several of silver, not at all productive. There are manufactures of coarse cloth, of baize and frieze, of counterpanes and other coarse stuffs; also of leather, paper, earthenware, porcelain at Moncloa, bricks and tiles, saltpetre, glass and crystal, guitar strings, chocolate. The extensive cotton manufactures of San Fernando, about 22 leagues from Madrid, have been for many years discontinued. Many women, especially in the *partido* of Getafe, are employed in the embroidery of tulle for mantillas. There is very little commerce beyond that for the supply of the capital with necessaries. Primary instruction not many years ago was deplorably neglected, but there has recently been some advance in this respect. The university of Alcalá has long been transferred to Madrid, so that the whole higher instruction of the province is centred in the capital.

On account of the elevated situation of this province, and its being surrounded with snow-covered summits, the air is at all seasons keen and penetrating, and even in the suffocating heats of summer the breeze is cold; yet the climate is generally salubrious.

MADRID, capital of the above province and of Spain, is situate in N. Lat. 40. 24. 57., W. Long. 3. 41. 51., on the left bank of the River Manzanares, an affluent of the Tagus, at an altitude of 2245 feet above sea-level. It occupies nearly the centre of the kingdom, being about 300 miles from the Atlantic, and an equal distance from the Mediterranean, 240 miles S.W. of Bayonne, and 350 E.N.E. of Lisbon. It stands on some sandy hills of little elevation, in the midst of an extensive plain, bounded to the view on only one side, by the mountains of Somosierra and Guadarrama. The basin in which it stands is of tertiary formation, consisting of gypsum, marl, meerschaum, and limestone. Owing to its elevation and exposure, the air is extremely subtle and keen. The mean temperature in winter is 43°, though the thermometer frequently indicates 32° and under; in summer the mean is 76°, while, during the S.E. wind, the thermometer often indicates 90° or 105° in the shade. These extremes, which have given rise to the adage, "*Tres meses de invierno, y nueve del infierno*" (three months of winter, and nine of hell), are very prejudicial to health, causing pulmonary diseases, which, with the convulsive colic, may be called endemic; pulmonia carrying off many victims every year at the beginning of winter, and during the long-continued colds of that season; while, even in the suffocating heats of July and August, the breezes from the snow-covered Guadarrama often sweep along the streets with a death-like chill. The natural insalubrity of the city is enhanced by the want of water, and by the neglect of sanitary precautions on the part of the inhabitants.

The form of Madrid is that of a square, with the corners rounded off; from E. to W. it measures about 2640 yards, and 2970 yards from N. to S. It is surrounded by a very

Madrid.

Madrid. poor wall, partly built of brick, partly of earth—the house walls in some quarters forming part. There are five gates (*puertas*), whose names indicate their position,—Alcalá, Bilbao, Segovia, Toledo, and Atocha,—and eleven *portillos*. Of these sixteen entrances, the finest is that by the Puerta de Alcalá, which terminates the Calle de Alcalá, the handsomest street in the town. The puerta is in the modern Ionic style, with three archways, and was erected by Charles III. in 1778. The Portillo de San Vicente, erected by the same monarch in 1775, deserves notice; it is built of Colmenar granite. The Puerta de Toledo, erected 1813–27, in honour of the restoration of Ferdinand VII., is a pretentious but heavy structure. Madrid is divided into ten districts, and consists of 512 streets and 70 plazas, large and small. The old streets are irregular, tortuous, and narrow, but the modern ones, especially in the E. part of the town, are broad and handsome. The Calle de Alcalá, already mentioned, which connects the Prado with the Puerta del Sol, is a very fine street, bordered on both sides with acacias, and containing some elegant buildings; but its irregularity in point of width and level detract much from its appearance. The Calle Mayor, De la Montera, Caballero de Gracia, Hortaleza, Fuencarral, Carrera de San Geronimo, and Atocha, deserve notice. The Plaza Mayor is a rectangle of about 400 feet by 306; the houses are uniform in height and decoration, and have porticos. Here the executions and royal bull fights were celebrated, the royal family viewing them from the Panaderia. There is in the centre a bronze equestrian statue of Philip III., designed by Pantoja, and cast by Juan de Bologna, which has been much admired. The Puerta del Sol, formerly the east gate and tower of the city, having on its front a representation of the sun, is now the central plaza, and the favourite lounge and place of most traffic in the city. It is situate in the confluence of four principal streets, and contains only one building worthy of attention, the Casa de Correos. The Plaza de las Cortes, so called from the house of deputies, is remarkable as containing the fine statue of Cervantes by Solà, erected in 1835. The most frequented promenade is the Prado on the east and north sides of the city, in length about 9650 feet. It was planted by the Conde de Aranda in the time of Charles III., and laid out by José Hermonvilla. It contains some indifferent monuments and fountains. On the E. are the gardens of the Buen Retiro laid out by Olivares; on the W. the Florida; on the N. the Delicias; and on the S., Chamberri. These are less frequented.

Madrid has small architectural pretensions, and is almost wholly without Roman, Moorish, or Gothic remains. Her most ancient public buildings are in the worst style of the renaissance, and the private houses in general mean and incommodious. Like the other large towns in Spain, Madrid is disfigured with numerous heavy-looking convents. There are altogether sixteen churches and sixty-one convents, besides chapels and convents which have been put to other uses. The church of Maria de la Almudena is the *iglesia mayor*, and the most ancient, having been a Moorish mosque; it is small and of no merit. Perhaps the finest church in Madrid is that of the convent (*de monjas*) of La Encarnacion, in the form of a Latin cross, and with Ionic decorations; its high altar is very fine. The chapel of Las Salesas Viejas, a large convent of nuns, erected by Barbara, queen of Ferdinand VI., as a seminary and retreat for herself, has been converted into a parish church. It is a fine Corinthian structure, and the marbles of the high altar are magnificent. The convent of San Geronimo, founded by Enrique IV., one of the few Gothic specimens, contained numerous marble sepulchres of eminent men, which were mostly destroyed by the French, with those in the church of San Martin. The structures for civil purposes are better, and the Palacio del Congreso de Diputados, begun in 1843,

deserves particular mention. The Aduana, erected 1769, is a fine large building in the Calle de Alcalá, and contains various public offices. The barracks of the Life-Guards, occupied by cavalry, is an enormous but tasteless erection of the last century.

There are two royal residences in the city,—the Palacio Real and the Palacio de Buen Retiro. The former is one of the largest and finest in Europe. At first view its aspect is very imposing; a closer inspection disappoints. It is built on the site of the ancient Moorish Alcazar. When Charles V. made Madrid his residence in 1532, he caused the Alcazar to be improved and enlarged, and the obstructing houses to be demolished. Philip II., and the succeeding monarchs, continued the improvements; but the whole was destroyed by fire in 1734. The present edifice was begun in 1738, under Philip V., by Sachetti of Turin, and was not finished till 1764; the palace of Buen Retiro being occupied in the meanwhile. The wings and hanging gardens are still unfinished. It is a square of 470 feet each way, and about 100 feet in height, vaulted throughout. The reception-room is very magnificent. Marbles are used profusely for the floors and doorways; and the ceilings are painted by Mengs, Antonio Velasquez, Maella, Jaquinto, Bayeu, and Tiépolo. This palace contains the Bibliotheca de Camara and the Armeria Real. The former consists of about 200,000 volumes, and from 2000 to 3000 MSS. (See LIBRARIES). The latter, occupying the south façade, is perhaps the finest armoury in the world, containing numberless weapons, native and foreign, of all ages. The royal chapel, though plundered in 1808 of its fine pictures, is still very magnificent. The order is Corinthian; the decorations very splendid. The Palacio de Buen Retiro exists in a state nearly approaching to desolation, the damage done by the French never having been entirely repaired. The oldest part, built by Olivares for Philip IV., is a large regular square, but subsequent additions and improvements have destroyed the harmony of the whole. The palaces of the *grandees*, if we except those of the Duque de Liria, the Conde de Altamira, and Don José Salamanca, are not remarkable. Those of Alba, Liria, and Medinaceli contain valuable galleries of pictures. There are eight theatres: the Teatro del Principe, erected in 1806 by the architect Villanueva, is the most elegant and best arranged in the city; the Teatro del Cruz, erected in 1737 by Ribera, and capable of containing 1500 persons, is in exceedingly bad taste, and inconveniently constructed. The Plaza de Toros, built in 1749, is about 1100 feet in circumference, and contains 12,000 spectators; and the bull-fights are held between the months of April and November. One of the finest public galleries in the world is the Museo de Pinturas, situate in the Prado—a heavy, indifferent building,—which contains the collections formed by Charles V., Philip II., and Philip IV., and numbered 1833 pictures in 1850. The specimens of Raphael, Titian, Murillo, and especially Velasquez, are numerous and remarkable.

There are 60 public schools of primary education in Madrid, besides *escuelas pias*, *colegios*, and private institutions. Modern educational movements have not left Madrid unaffected, and great improvements in this respect have taken place within the last fifteen years. Female education is chiefly carried on in convents. The university of Alcalá, founded by Cardinal Ximenes in 1508, was transferred in 1836 to Madrid, and has since that time undergone much reform and extension. In 1845 chairs of medicine, natural history, and astronomy were added. There is a school for the blind, one for deaf-mutes, and schools of engineering, military science, and the fine arts. Among educational institutions may be reckoned the botanical garden, laid out in 1781; the library of San Isidro, which contains about 60,000 volumes, and the museum of natural science, formed chiefly under Charles III. on the several purchased collections augmented by contributions from the

Madrid.

Madridejos
||
Madrigal.

Spanish Indies. The collection contains the most magnificent crystals of emerald in the world, and fine ores of the precious metals. The principal learned society (*Academia*) is the Royal Spanish Academy, founded in 1713, for the study and improvement of the Castilian language. The Academy of History possesses a fine collection of coins and medals; there are also academies of natural science, archaeology, fine arts, ecclesiastical science, and legislation. Of these associations it may be said that their projects are much more magnificent than their actual results.

The hospitals of Madrid are very numerous; the principal is the General or United Hospital, a very large building in the Calle de Atocha, containing 1526 beds, and receiving patients of both sexes. There are three founding hospitals, and two for orphans. The military hospital is large and well conducted; it occupies the former seminary of the nobility in the Plazuela del Seminario. There are, besides, hospitals for the reception of foreigners, and for the natives of several Spanish provinces.

The manufactures of Madrid are inconsiderable; every article of food and clothing, almost without exception, is imported. Tapestry, carpets, and china are manufactured for the court. Deserving of notice are the saltpetre works, the manufacture of hats, that of looking-glasses, and some breweries. Little wine is grown near the capital, and not much fruit; but the markets are well supplied, and regularly, from all quarters of the kingdom.

The environs of the city are uninteresting; the sole attractive points being the royal villas of La Moncloa, on the road to the Escorial, close to the Manzanares, El Pardo, a fine hunting-seat restored by Charles III.; and La Vista Alegre. About 3 miles on the Toledo road are the Caravanchales, two villages of pleasurable resort. The village of Loeches has a convent remarkable for a fine collection of paintings. A railway between Madrid and Aranjuez has been constructed; others are contemplated.

Spanish archaeologists have claimed for Madrid a very high antiquity; but its origin and that of its name are exceedingly obscure. The immediate source of the latter is the Arabic appellation *Majrit*. The earliest authentic historical mention of the town corresponds to A.D. 932. It first rose to importance when Charles V., benefiting by its keen air, made it his occasional residence, and founded the Palacio Real; Philip II. formed a similar attachment, and created it his capital and "only court" in 1560. Fruitless attempts have been repeatedly made by subsequent monarchs to transfer the seat of empire to Valladolid or Seville.

The population of Madrid amounted in 1845 to 216,740, including the garrison. This population, composed of natives of all the Spanish provinces, has little common character beyond that of indolence.

MADRIDEJOS, a town of Spain, province of Toledo, on the high road of Andalucía, which crosses the plains of La Mancha, 40 miles S.E. of Toledo. The streets are broad and regular; but the houses are old, built of *tapia*, and have a mean appearance. The church of the Franciscan nuns, and the convent San Cristo del Prado, are good edifices; the latter is surrounded with trees, and has a fine promenade in its vicinity,—the only place of recreation in the town. Madridejos is supplied with water from wells, and from springs in the neighbouring hills. The manufacture of bombasin has much decayed of late years in the town, from the cheapness of foreign productions. The surrounding district is of good soil, and grows wheat, rye, wine, oil, and saffron. There are also numerous quarries of gypsum and limestone. Market-day, Saturday. Pop. 5160.

MADRIGAL, a short poem, composed of a number of free and unequal verses, neither confined to the regularity of a sonnet, nor to the point or antithesis of an epigram, but only consisting of some tender and delicate thought, expressed with elegant simplicity. The derivation of the

||
Mæcenæ.

word cannot be determined. The earliest madrigals were those of Lemmo of Pistoia. The composition of madrigals attained a very high degree of excellence in England during the reign of Elizabeth, and are said to be in no way inferior to those of Italy. Orlando Gibbons is the best known among the English madrigal composers; Marenzio and Clari among those of Italy.

MADURA, an extensive district of Hindustan, situate within the presidency of Madras. It is bounded on the N. by the districts of Trichinopoly and Coimbatore; on the N.E. by Tanjore and the native state of Poodoocottah; on the E. by Palk's Straits and Tanjore; on the S. by the Gulf of Manaar, and on the W. by Travancore. It lies between Lat. 9. 5. and 10. 54., Long. 77. 15. and 79. 15., and has an area of 10,700 square miles. The principal river is the Vygar, which, after a course of about 180 miles, falls into Palk's Strait, a short distance N.W. of the headland of Tonitorai. The climate of the hills is mild and genial in summer. It is said, moreover, to be cold in January, when the ground is covered with hoar-frosts during the morning; but the climate of the plain is characterized by dryness and heat, the thermometer having been known to reach 115°, and according to some, 130°. This district participates in the vicissitudes of the two monsoons. Its population, including Dindigul, amounts to 1,756,791. The territory came into the possession of the British in 1801. The name of the capital is Madura, an ancient city, the four sides of which front nearly the four cardinal points. It was formerly well fortified with a ditch, rampart, and square towers; and from 1740 to 1760 sustained many sieges, and was often in possession of refractory Polygars. Since it has come into the possession of the British, considerable improvements have been made in the town by laying it out with wide streets, market-places, and accommodation for travellers, whereby the public health and convenience have been greatly promoted. E. Long. 78. 10., N. Lat. 9. 55. (E.T.) MADURA, an island in the Eastern Archipelago, lying immediately N.E. of Java, with which island it is conjoined under the Dutch government. (See JAVA.)

MEANDER, a river which rises in Phrygia, not far from Celænæ, and on leaving that province forming the boundary between Caria and Lydia. It fell into the Ægean Sea between Miletus and Priene, which latter city had gradually been removed 40 stadia from the sea by the muddy deposits of the river. It was remarkable for the winding character of its stream; hence the origin of the word "to meander." (Str. xii. 577, 579; Pl. v. 31, 3.) It is joined by the Marsyas, Obrimas, Glaucus, Lycus, &c. It is now the *Meinder*, or *Boyük Meinder*.

MÆCENAS, CAIUS CILNIUS, the friend and counsellor of Augustus Cæsar, a man whose name has become a synonyme for a patron of literature, from the munificent and generous support he afforded to the learned. He flourished from about 41 to 8 B.C. He was very generally considered by the ancients as descended from the royal line of Etruria. The family of the Cilnii is mentioned by Livy (x. 3) as very powerful at Arretium, now Arezzo, B.C. 300. We have no account of the early years of Mæcenas, but there is little doubt that his education was carefully attended to, and becoming the dignity of his birth. In what way he acquired the friendship of Octavius we have no means of knowing; but we find him actively engaged in his cause immediately after the murder of Julius Cæsar, B.C. 44. His talents seem to have been particularly adapted for the administration of the civil affairs of government, and we find him more frequently thus engaged, than in the active business of war. He was employed (B.C. 40) to negotiate the marriage between Augustus and Scribonia, the sister of Scribonius Libo, the father-in-law of Sextus Pompey, with the view of securing a channel by which he might obtain peace with Pompey if circumstances should require it (Appian. B. C.

Mæcenas. v. 53). The same year Mæcenas was one of the commissioners appointed to negotiate the peace between Antony and Octavius at Brundisium, which was sealed by the marriage of Octavia and Antony (v. 64). He was again the principal person employed in the conference between Octavius and Antony (B.C. 37), on the banks of the river between Metapontum and Tarentum, when peace was agreed upon (v. 92). He had the command of the whole of Italy and Rome at the time of the battle of Actium, B.C. 31, at which period he put down a conspiracy entered into by Lepidus the son of the triumvir (iv. 50; Vell. Pat. ii. 88). The victory at Actium having placed the Roman empire in the hands of Octavius, he consulted with his friends, Agrippa and Mæcenas, whether he ought not to abdicate his authority. Agrippa advised him to restore the republic, but Mæcenas was of a contrary opinion. The speeches which they each delivered are given by Dion Cassius (41, 1-40). Augustus adopted the opinion of Mæcenas, and was guided in all his more important transactions by his advice, having confidence not only in his good sense and discretion, but in the integrity of his character. To Mæcenas, therefore, may in a great measure be ascribed the glory of his reign. After his death, Augustus frequently regretted that he had no longer a friend to assist him; and when he had committed any act of which he repented, he used to say, that if Mæcenas or Agrippa had been alive, he would not have had cause to reproach himself for the folly of his conduct (Sen. *De Benef.* vi. 32). It is said that Mæcenas one day observed Augustus on the point of condemning some persons to death, and being unable to approach the tribunal on account of the crowd, he threw a paper to him, on which he had inscribed these words, "Descend from the tribunal, thou butcher;" upon which Augustus, struck by the admonition, left the judgment-seat without passing sentence. The palace of Mæcenas was on the Esquiline Hill, and his gardens are frequently mentioned as occupying the ground which had been previously employed as the place of burial for the poor (Tacit. *Ann.* xv. 39). It is, however, to his generous patronage of the learned that he is principally indebted for his fame; and their gratitude has amply repaid all the attention he may have bestowed on them. His palace was the common resort of all the literary characters of his age. There might be found Virgil and Horace, Varius, famed for his tragedies, Propertius, Domitius Marsus the rival of Catullus, Valgius, Plotius, and Tucca. It was through Mæcenas that the learned had access to the emperor, and were loaded with his favours. Horace gives a very interesting account of his introduction to Mæcenas, which must have taken place as early as B.C. 40, when both the poet and Mæcenas were still young. To Mæcenas Horace was indebted for his Sabine farm; and Virgil was through him restored to his paternal estate near Mantua. Virgil dedicated the *Georgics* to his patron; and to him Propertius has dedicated several of his poems. It is needless to add, that much of the poetry of Horace was also addressed to him. Mæcenas has been accused, however, of being devoted to pleasure; but his faults were those of the age in which he lived, and his virtues were his own (Senec. *Epist.* 92, 114). Virgil died many years before Mæcenas, B.C. 19; but whether Horace predeceased Mæcenas or not is uncertain. Horace died in the month of November B.C. 8 (Sueton.); and Dion Cassius (41, 3) mentions the death of Mæcenas towards the close of the same year. The clause in the will of Mæcenas, in which he recommends to Augustus his friend Horace, would lead us to conclude that Horace survived him. At all events, only a few months could have intervened between their deaths. He was married to Terentia, a woman of a disagreeable temper, from whom he frequently separated; but found his happiness so dependent on her smiles, that he soon received her back to his arms (Sen. *De Prov.* 3). Pliny states that

the health of Mæcenas was at all times delicate; and that for the last three years of his life he scarcely enjoyed an hour's sleep (vii. 52, 2). Of the writings of Mæcenas we have nothing remaining except a few epigrams, which are published in the *Anthologia Latina* of Burmann (i. 53, ii. 225, iii. 149). He was also the author of two tragedies, *Prometheus* and *Octavia*; and is supposed to have written memoirs to serve for the history of Augustus. (See Fabricius, *Bibliotheca Latina*, iii. 964; *De Mæcenatis Vita, Moribus, et Rebus Gestis*, auct. Meibom, Lugd. Bat. 1653; Lion, *Mæcenationa*, Götting, 1824; *Mémoires de l'Acad. des Inscrip.* xiii.) In Italian there is a *Life* by Cenni, Rome, 1684; by Dini, Venice, 1704: in German, by Benemann, Leips. 1744; by Lign, Götting, 1824; and by Frandsen, Altona, 1843: in French, by Richer, Paris, 1746. The only *Life* in English is by Dr Ralph Schomberg, London, 1766, 12mo.

MAELSTROM, or **MOSKOESTROM**, a whirlpool off the coast of Norway to the S.W. of the Lofoden Islands; N. Lat. 67. 48., E. Long. 12. It consists of a swift current, running every six hours alternately from N. to S. and from S. to N., contrary to the motion of the tide, thus producing a wide eddy, the noise of which is heard to a great distance. Whatever small vessel comes within its reach is immediately sucked in, and after being dashed to pieces on the rocks at the bottom is thrown up again by the whirlpool. It is least agitated about the turn of the tide, and it is then only that it can be approached with safety. The diameter of the whirlpool is about $1\frac{1}{2}$ miles.

MÆOTIS, **PALUS** or **LACUS**, in *Ancient Geography*, the modern Sea of Azoff, which see.

MAESTLIN, **MICHAEL**, a celebrated astronomer of Germany, born about 1542 in Würtemberg. He spent his youth in Italy, and during his residence in that country made the acquaintance of Galileo, whom it is said the powerful argumentation of Maestlin induced to renounce the system of Ptolemy in favour of that of Copernicus. On his return to Germany, he was appointed professor of mathematics at Tübingen, where he had Kepler for his pupil, and for whose instruction in mathematical science he declined to receive any pecuniary remuneration. Kepler afterwards speaks of his generous master in terms of gratitude and admiration, and found occasion, when Maestlin subsequently stood in need of sympathy and aid, of giving substantial expression to his affection for him. Maestlin died at Tübingen in 1590. His works are,—*De Stellâ nova, Ephemerides*, 1551; *Thesis de Eclipsibus; Observatio et Demonstratio Cometæ anni 1577 et 1578*, 4to, Tübing. 1578; *Consideratio et Observatio Cometæ 1580*, Heideib. 1581; *Alterum Examen Gregoriani Calendarii*, Tübing. 4to, 1586; *Epitomæ Astronomiæ*, Tübing. 1597.

MAESTRICHT, a strongly-fortified town of Holland, and capital of the duchy of Limburg, is situate on the left bank of the Meuse, and connected by a stone bridge of nine arches, with its suburb of Wych on the opposite bank. This is one of the strongest fortresses in Europe, being surrounded by walls and ditches, and having also a number of detached bastions, an arsenal and military magazine, and a citadel or fortress, called St Pierre, on a neighbouring height. By opening sluices a great part of the surrounding country may be laid under water. Under the hill of Petersberg, on which the citadel stands, is a subterranean stone quarry, covering a space of 13 miles by 6, and said to be intersected by 16,000 passages, forming a most intricate labyrinth. The rock is a soft, yellowish stone, abounding in curious and interesting fossils. The town is well and regularly built, having wide, clean, and well-paved streets. The town-hall, built in 1662, stands in the centre of the great market-place, and is said to be one of the finest edifices in Holland. The church of St Gervais, a fine Romanesque edifice, dating probably from the tenth century, is ornamented with five towers, and has a splendid portal. There

||
Maestricht.

Maffei. are six Roman Catholic and three Calvinistic churches, two hospitals, two orphan asylums, a lazaretto, lyceum, public library, and society of agriculture. The chief manufactures are,—woollen and cotton stuffs, leather, soap, tobacco, fire-arms, beer, and spirits. Maestricht is connected with Aix-la-Chapelle by railway, and also carries on a considerable trade with various places on the Meuse. It has frequently suffered from sieges. In 1579 the Spaniards, under the Duke of Parma, took it by assault after a siege of four months, and put the garrison and most of the townspeople to the sword. It was also taken by Louis XIV., but was unsuccessfully attacked by William III. of England. It was bravely and successfully defended by its garrison against the Belgians in 1830. Pop. (1854) 24,394.

MAFFEI, FRANCESCO SCIPIONE, *Marquis*, a celebrated Italian writer, was born at Verona in 1675, and studied five years at the college of Parma, where he gave early manifestations of eminent ability, both in literature and science. Born of a noble family, and early admitted to familiar intercourse with men and women of culture and refinement, Maffei's mind was favourably directed from the idle frivolities with which a person of his rank is apt to waste his youth, and turned towards those nobler pursuits in which he afterwards won for himself so distinguished a name. He visited Rome in 1699, and besides acquainting himself with the monuments of that city, gained the friendship of some of her more distinguished men. Eager for all sorts of distinction, he, in 1704, joined his brother Alessandro, then lieutenant-general in the Bavarian service, and as a volunteer reaped the laurels of a soldier at the battle of Donawert. The evidence of personal bravery which S. Maffei here displayed gave dignity to his pen when he lifted it afterwards in his *Della Scienza Chiamata Cavalleresca*, to denounce the practice of duelling, then so common in his native country. In conjunction with Apostolo Zeno and Vallisneri, Maffei commenced, in 1710, the *Giornale dei Letterati*, the earliest literary journal in Italy. His *Osservazioni Letterarie*, published in 1737–40, in 6 vols., was a continuation of his literary journal after its discontinuance in 1730. He took great interest in the reformation of the Italian theatres, then in a deplorable condition; and in his work, *Trattato dei Teatri Antichi e Moderni*, defended the histrionic art against the denunciation of Father Concina, a performance which met with the approbation of Pope Benedict XIV. Nor did his efforts stop here; in 1713 he wrote, and brought upon the stage, the tragedy of *La Merope*, a work which was received with very great applause, and won for its author the title of the "Veronese Sophocles" from the celebrated Voltaire. Maffei now directed his attention more exclusively to political studies, and brought out his greatest work, the *Verona Illustrata*, a history and description of his native city, remarkable alike for extensive learning, historical insight, and elegant writing. The reputation of Maffei was spread over Europe, when, in 1732, he visited Paris, and collected materials for his *Gallia Antiquitates*, which he published at Paris during the following year. He afterwards went to England, where he was received at the court of George II., was made a member of the Royal Society, and had the degree of LL.D. conferred on him by the university of Oxford. He spent four years in travel, and returned to Italy by Holland and Germany. He died at Verona in 1755, aged eighty years. In addition to the works already mentioned, Maffei wrote three treatises against the popular belief in magic; one on the legitimacy of receiving interest on a loan of money, entitled *Dell' Impiego del Denaro* (1746), for which he suffered a temporary exile, through the influence of the Jansenists; and one, the *Museum Veronense*, on ancient inscriptions and hieroglyphics, published at Verona in 1749. A collected edition of Maffei's works was published at Venice, in 28 vols. 8vo, 1790.

MAGADOXO, or **MUKDEESHA**, an Arabian town on the E. coast of Africa, N. Lat. 2. 2., E. Long. 45. 25. It is the capital of a state of the same name, and is a place of very considerable trade, exporting ivory, gum, and a peculiar kind of cloth; and importing sugar, dates, salt fish, arms, and slaves. The town is walled, and is divided into two parts, one of which is composed entirely of tombs, while the other contains about 150 stone and a number of wooden houses, and an Arabian mosque. Pop. probably about 4000. The state extends along the coast for about 240 miles, and is estimated to have a population of about 150,000. Its sovereign is a tributary to the Iman of Muscat in Arabia.

MAGALHAENS, or **MAGELLAN**, **FERNANDO**, the discoverer of the straits known by his name, is said to have been born at Oporto, in Portugal, in the latter half of the fifteenth century. Entering the Portuguese navy at an early age, he served in the East Indies for five years under Albuquerque, and bore a distinguished part in the siege of Malacca in 1511. As he thought, however, that his achievements were not duly rewarded, he returned to Portugal to make a personal appeal for promotion to King Emmanuel himself, but was again unsuccessful. Accordingly, he opened a communication with Charles V. of Spain. Referring to the bull of Pope Alexander VI., that had divided the globe into two parts, and had assigned as their distinctive spheres of discovery the western half to the Spaniards and the eastern to the Portuguese, Magellan endeavoured to prove to that monarch that the Moluccas, then claimed by Portugal, lay within the Spanish half of the world. He also volunteered to settle the question beyond all doubt by sailing to the Moluccas by a westward instead of an eastward course. His proposal was accepted by the Spanish king; and, accordingly, on the 20th September 1519, Magellan sailed from San Lucar, in command of a squadron of five ships, with 236 men on board, and steered directly for Rio Janeiro. After taking on board at that port a fresh supply of provisions, he sailed southward along the coast, and on the 13th March 1520 entered a bay on the shore of Patagonia, to which he gave the name of San Julian. While the fleet lay wintering here, three of the captains, impatient perhaps of the control of a Portuguese, broke out into open mutiny, and by their example began to spread discontent among the crews. In a short time, however, Magellan had one of the mutineers secretly slain, another publicly executed, and the third thrust ashore on the inhospitable coast of Patagonia. On the 21st October 1520, he doubled the headland which he called Cape Virgins, and arrived at the mouth of the straits which are now known by his name. With the utmost difficulty he induced his sailors to venture into the unknown passage. One of his ships was wrecked at the entrance of the straits, another turned back in the middle; but, on the 28th of November, the remaining three, to the great joy of Magellan, issued forth into the vast ocean. Boldly directing their course across this untraversed sea, to which, on account of its calmness, they gave the name of Pacific, and sailing for more than three months without seeing land, the crews suffered great hardships from disease and want of food. On the 6th March 1521, he discovered the group of islands which, on account of the thievish propensities of the inhabitants, he called *Iadrones*. He then proceeded to another cluster of islands, formerly unknown, but afterwards called the Philippines. There the prince of the island of Zebu agreed to become tributary to Spain, on condition that Magellan should render him supreme over the chieftains of the other islands in the group. In fulfilling this agreement, Magellan encountered an obstinate resistance from the inhabitants of the small island of Matan. On 27th April 1521, after fighting for an entire day, he was forced to retreat, through lack of ammunition, and in the subsequent confusion he was felled by a stone, and despatched

Magalhaens.

Magdalena by the thrust of a lance. His fleet was conducted home by Sebastian del Cano.

MAGDALENA, a river in South America, the second in length in the republic of New Granada, rises at the junction of the Central and Eastern Cordilleras of the Andes, in the small Lake of Papus; N. Lat. 1. 58., W. Long. 76. 25. It flows northwards for 500 miles between these two ranges, and then enters the plain. After receiving from the W. the Cauca, which is nearly as large as itself, in N. Lat. 9. 25., it divides into several branches and falls into the Caribbean Sea, Lat. 11. 8., Long. 74. 50. The total length is estimated at about 800 miles, and it is navigable as far up as Honda, 435 miles from its mouth. The Magdalena is a rapid river, and the amount of its descent and the force of its current are such, that for some distance from its mouth the waters may be distinguished by their freshness from the surrounding ocean. Rapids and cataracts frequently interrupt its course, and its banks are infested with caymans and crocodiles, which, along with the excessive heat of the climate, and the swarms of mosquitoes, render the progress of the navigator anything but safe and agreeable. It is, however, the main channel of communication between the provinces in the interior and the sea. Besides the Cauca, it receives a number of smaller tributaries, the chief of which are the Sogamosa and Bogota, from the E. The chief towns on its banks are,—Neiva, Tocama, Honda, and Mompo. The department of the same name in the N. of the republic has an estimated area of about 52,000 square miles, and a population of about 337,000. It is divided into four provinces, and its chief town is Cartagena on the sea-coast.

MAGDEBURG, a fortified town of Prussia, capital of the province of Saxony, and of a cognominal government, is situate on the left bank of the Elbe, 90 miles S.W. from Berlin, with which, as well as with Hamburg, Brunswick, Leipzig, and other places, it is connected by railway. It ranks as a fortress of the first class; and in consequence of the additions and improvements which its fortifications have received since the war, it is now considered one of the strongest places in Europe. On account of its great extent it could not be invested by an army of less than from 50,000 to 100,000 men. The citadel, on an island in the Elbe, serves also as a state prison: Lafayette, Carnot, and others, have been confined in it. Magdeburg consists of three parts,—Alstadt, Neumarkt, and Friedrichstadt, besides the suburbs of Sudenburg and Neustadt. With the exception of one spacious street, called the Broadway, all the streets are narrow and crooked. There are two large public squares, the largest and finest of which is the *Domplatz*, in which is the cathedral; the other, the market-place, has in the centre an equestrian statue of the Emperor Otto, erected in 973. The *Fürstenwall*, a sort of terrace extending along the Elbe, and planted with trees, forms a very agreeable promenade. The public gardens outside the Sudenberger Gate, and by the side of the Elbe, are tastefully laid out, and much resorted to. Magdeburg contains few ancient public buildings of note, having been almost burned to the ground by Tilly in 1631, when only 139 houses were left standing. Fortunately, among those saved was the cathedral, one of the finest Gothic edifices of Northern Germany, erected between 1211 and 1363, and restored at great cost, 1825–34. It is built entirely of freestone, is 362 feet long, and has two lofty towers. It contains numerous tombs and monuments, among which is that of Otto the Great and his empress. Among the other churches are the church of the Virgin, built in the eleventh century, and the French Reformed church, dating from the latter part of the seventeenth century. The town-hall, government-house, artillery barracks, and theatre, are among the chief of its other buildings. Magdeburg is the see of a bishop, and, as the capital of a province, is the seat of a

number of important courts and offices. It has also numerous benevolent and educational institutions, among which are several hospitals and orphan asylums, a deaf-mute institution, ecclesiastical gymnasium, female high school, normal seminary, and schools for agriculture, commerce, surgery, &c.

Magdeburg is also one of the most important trading and manufacturing towns of Germany. From its position on the Elbe, and its extensive railway connection with all parts of Germany, it is an important entrepôt of trade for a great part of Germany. Steamboats ply regularly between Hamburg and Magdeburg; and by means of a canal connecting the Elbe with the Havel, it has direct water communication with Berlin and other places. The manufactures comprise woollen, linen, and cotton stuffs; gloves, lace, hats, tobacco, and earthenware. Magdeburg existed as a town as early as the eighth century. It has frequently suffered from sieges, especially in 1631, when it was taken and sacked by the imperialists under Tilly. It was taken by the French in 1806, and annexed to the then kingdom of Westphalia. In 1849 Magdeburg contained 50,996 inhabitants, besides 5185 military; the suburb of Neustadt, 10,023; and that of Sudenburg, 4284 inhabitants. In 1853 the total population of city and suburbs was 77,159. The government of Magdeburg is one of the three that compose the province of Saxony. It is divided into fifteen circles, and has an area of 4447 square miles, with, in 1852, a population of 714,268. Its soil is of great fertility, and is well cultivated.

MAGELLAN, or **MAGALHANS**, STRAIT OF, an arm of the sea which separates Patagonia from the group of islands lying to the S. of South America, of which the principal is Tierra del Fuego. It received its name from Ferdinand Magellan, who first sailed through it from the Atlantic to the Pacific. For some time after this it was thought to be the only communication between the two oceans; but since Cape Horn has been doubled, it is little used on account of the difficulty of navigation. The entrance to the channel at the eastern end is situate in about S. Lat. 52., and is 15 miles in breadth, while that on the side of the Pacific extends to 33 miles. There is, however, another arm reaching to the Pacific by Cockburn Channel and Magdalen Sound. The breadth of the main strait varies very considerably, being at one point not more than $1\frac{1}{2}$ miles across. The middle of the strait is much farther S. than either of its extremities, and the whole length is nearly 300 miles. It is bounded by precipitous rocks, rising in some places to 3000 or 4000 feet above the level of the sea, and the depth in some places is so great as to give no soundings with a line of 1500 feet. Towards the western mouth the strait is broken up by a number of islands.

MAGENDIE, **FRANÇOIS**, an eminent physiologist, the son of a physician in Paris, was born at Bordeaux in October 1783. At an early age he was removed to the capital; and after attending school for some time, became a pupil of Boyer, the eminent surgeon. He was then successively appointed *aide d'anatomie* in the Faculty of Medicine, a demonstrator, and physician to the Hotel Dieu. In 1816 he published *Précis Élémentaire de Physiologie*, 8vo, a work, which, in some of its subsequent editions, appeared under the title of *Elémens de Physiologie*. His *Recherches Physiologiques et Médicales sur les Causes, les Symptômes, et le Traitement de la Gravelle*, was published at Paris in 1818. In 1819 he became a member of the Academy of Sciences. One of his most important works, *Formulaire pour la Préparation et Emploi de plusieurs nouveaux Médicaments*, appeared in 1821, and was soon after translated into all the European languages. In 1831 Magendie became professor of anatomy in the College of France. He published in 1839 *Leçons sur les Phénomènes Physique de la Vie*, and *Leçons sur les Fonctions et les Maladies du Système Nerveux*. In 1842 was printed at Paris his *Recherches Philosophiques et Cliniques sur le Liquide Cephalo-Rachi-*

dien ou Cerebro-Spinal. Magendie died in October 1855. Among his important services to science may be named his demonstration that the two roots of the spinal nerves have two distinct functions. Sir Charles Bell had previously shown that the nerves sometimes perform the double function of sensation and volition, and Magendie clearly established and admirably illustrated the fact, that the two roots of the spinal nerves are always devoted to two separate functions. He likewise discovered that the veins are the principal agents in absorption; that food destitute of nitrogen is not nutritious; and that strychnia produces asphyxia by acting upon the spinal cord, and by thus paralyzing the nerves of respiration.

MAGGI, JEROME, in Latin *Magius*, one of the most learned men of the sixteenth century, was born at Anghiari in Tuscany. He applied himself to all the sciences, and even to the art of war; and distinguished himself so much in this last study, that when the Turks besieged Famagusta, he destroyed all the works of the besiegers by means of mines and fire-machines, and in an instant overthrew what had cost them infinite labour. But the Ottomans took the city in 1571, plundered his library, carried him loaded with chains to Constantinople, and after treating him in the most inhuman and barbarous manner, caused him to be strangled in prison in 1572.

MAGGIORE, LAGO. See LAGO MAGGIORE.

MAGI, the caste of hereditary priests under the Medes and Persians. Some derive their name from *mog*, or *mag*, which signifies priest in the Pehlevi language. They were in exclusive possession of scientific knowledge; and so celebrated were they in astrology and enchantment, that their name was given to all other kinds of enchanters and magicians. We find the word also used to denote any men distinguished for their wisdom. Thus the wise men of the east, in Matt. ii. 1, 7, 16, are termed Magi; and it is not difficult to perceive how, in the minds of the superstitious vulgar, this class of men should early come to be regarded under this twofold aspect. The grand doctrine of the ancient Magi, previous to the reformation effected among them by Zoroaster, was that of opposition, or strife, as the parent and original cause of all things. The two great principles which waged continual warfare throughout the universe were those of light and darkness, of good and evil, Ormuzd and Ahriman, which were destined to divide the dominion of the world, now preserving, now destroying finite things, till the final struggle should arrive, when darkness should be swallowed up of light, and the good should reign for ever. To seize upon and master those hostile powers was the chief task of the Magi, and they held that this could be effected by prayer and a true knowledge of the laws of opposition. When once this mastery was obtained, all subject to those powers were at their disposal: they could pry into futurity, raise the dead, and accomplish countless other supernatural triumphs over the limitation and suffering to which man is naturally subjected. That this system had its origin in the endeavours which thoughtful men perpetually exert after an intelligible explanation of the universe, there can be little doubt; and it can be as little doubted that their art, so far as it was real, had its foundation in a superior knowledge of the powers of nature. But what sprung originally from a love of truth, from the scientific tendencies of the human mind, could soon, in the hands of the dishonest and the grasping, be prostituted to fulfil the ends of vulgar avarice and sordid ambition; and hence the degradation of the *wise man*, the priest of science, into the *magician*, the wonder-worker, with his magical *theurgia* and wicked incantations.

Zoroaster reformed the religious doctrines and ceremonies of the Magi. (See ZOROASTER.) The best source of information for the study of the character and religion of the eastern Magi is to be found among the works of An-

quetil du Perron, who brought to Europe the celebrated books called the *Zendavesta*. (See vols. xxxiv. and xxxix. of the *Memoires de l'Academie des Inscriptions*.) Interesting information may also be obtained respecting the Magi and magic in Klenker's *Zendavesta* and *Magikon*; also, Creuzer's *Symbolik und Mythologie*; also, Windischmann and Conrad Horst on *Magic*; and Sir Walter Scott's *Demomology and Witchcraft*.

MAGIC SQUARE, a square figure, formed of a series of numbers in mathematical proportion, so disposed in parallel and equal ranks, that the sums of each row, taken either perpendicularly, horizontally, or diagonally, are equal.

Let the several numbers which compose any square number (for instance, 1, 2, 3, 4, 5, &c., to 25, the square number, inclusive) be disposed in their natural order after each other in a square figure of twenty-five cells, each in its cell; if now you change the order of these numbers, and dispose them in the cells in such manner that the five numbers which fill a horizontal rank of cells, being added together, shall make the same sum with the five numbers in any other rank of cells, whether horizontal or vertical, and even the same number with the five in each of the two diagonal ranks; this disposition of numbers is called a *magic square*, in opposition to the former disposition, which is called a *natural square*. See the following figures.

The Hindus, Egyptians, and Chinese are said to have been acquainted with those arrangements at a very early period, and adhered to the belief that such squares were possessed of powers of divination.

Moschopolus, a Greek author of no great antiquity, is the first who appears to have spoken of magic squares; and, by the age in which he lived, there is reason to imagine he did not look on them merely as a mathematician. However, he has left us some rules for their construction. In the treatise of Cornelius Agrippa, so much accused of magic, we find the squares of seven numbers, viz., from three to nine inclusive, disposed magically. Bachet applied himself to the study of magic squares, on the hint which he had taken from the planetary squares of Agrippa.

After him came Frenicle, who took the same subject in hand. He gives, however, no general demonstration of his methods, and frequently seems to have no other guide than chance. It is true, his book was not published by himself, nor did it appear till after his death, viz., in 1693.

In 1703 Poignard, a canon of Brussels, published a treatise on sublime magic squares. Before him there had been no magic squares constructed but for series of natural numbers that formed a square. Instead of taking all the numbers that fill a square, he only takes as many successive numbers as there are units in the side of the square, which, in this case, are six; and these six numbers alone he disposes in such manner in the thirty-six cells, that none of them are repeated twice in the same rank, whether it be horizontal, vertical, or diagonal; whence it follows, that all the ranks, taken all the ways possible, must always make the same sum, which Poignard calls repeated progression. Instead of being confined to take these numbers according to the series and succession of the natural numbers, that is, in arithmetical progression, he takes them

likewise in a geometrical progression, and even in an harmonical progression.

The book of Poignard gave occasion to M. de la Hire to turn his thoughts the same way, which he did with such success that he seems to have well nigh completed the theory of magic squares. He first considers uneven squares, all his predecessors on the subject having found the construction of even ones by much the most difficult; for which reason M. de la Hire reserves these for the last.

M. de la Hire proposes a general method for uneven squares, which has some similitude to the theory of compound motions, so useful and fertile in mechanics. As that consists in decomposing motions, and resolving them into others more simple, so does M. de la Hire's method consist in resolving the square that is to be constructed, into two simple and primitive squares.

As to the even squares, M. de la Hire constructs them, like the uneven ones, by two primitive squares; but the construction of primitives is different in general, and may be so a great number of ways; and those general differences admit of a great number of particular variations, which give as many different constructions of the same even square.

Dr Franklin seems to have carried this curious speculation farther than any of his predecessors. He constructed not only a magic square of squares, but likewise a magic circle of circles. The details are not, however, of such importance as to require particular notice in this place. In addition to the writers on this subject, already specified, we may add the names of Stifels, Leibnitz, Bachet, and Ozanam. (For a complete history of this subject, see Montucla, vol. i., p. 346; Hutton's *Dictionary*; and Ozanam and Montucla's *Mathematical Recreations*.)

MAGINN, WILLIAM, LL.D., one of the most spirited and versatile of modern writers, was born at Cork in 1793. He received his elementary education at an academy, conducted by his father, in his native town; and at the early age of ten years entered Trinity College, Dublin, which afterwards honoured him with the degree of LL.D. On leaving college, he divided his time between assisting his father as a schoolmaster and contributing literary articles to various periodical publications. He began to contribute to *Blackwood's Magazine* in 1819, and the wit, irony, fun, and eloquence of "Sir Morgan O'Doherty" continued to adorn the pages of that journal till Maginn's death. In 1823 he visited London, where his elegant scholarship, pungent satire, and spirited style, soon procured for him constant employment. Maginn became joint-editor of the *Standard* newspaper in 1828; and two years afterwards established *Fraser's Magazine*, a publication to which he contributed very extensively. His trenchant, caustic pen sometimes got him into difficulties with the fashionable novelists, and Maginn was not at all slow to give "satisfaction" when it was deemed necessary. Of a generous, witty, jovial nature, he found one of his greatest snares in his fondness for society. The brilliant humorist and boon companion was sought after by every one; and by too freely submitting to the temptation to which he was thus exposed, he found, while yet in his prime, that health and means had alike deserted him. In 1842 he was cast into the Fleet prison for debt, and on being released by passing through the Insolvent Court, found himself in a state of utter beggary, from which he was relieved by death during August of the same year. He died of consumption at Walton-on-the-Thames, aged forty-eight years.

MAGLIABECCHI, ANTONIO, a scholar remarkable for his great memory, was born at Florence in 1633. Deprived of his father at the age of seven, he was apprenticed, after receiving a scanty education, to a goldsmith in his native city. Soon afterwards his thirst for reading began

to appear, and with the aid of Ermini, librarian to the Cardinal de Medici, he speedily became an adept in Latin and Hebrew. Cultivated by the most unflagging application, his memory soon became noted for its strength and accuracy; and in course of time he was appointed librarian to Cosmo III., Grand Duke of Florence. In this congenial situation he became so absorbed in his studies as to neglect the ordinary comforts of life. A commodious apartment, which he occupied in virtue of his new office, was abandoned after a sojourn of four months. In his former dwelling, to which he retired, one chair served him for a seat during the day, and another for a bed during the night. His old thread-bare cloak was also the coverlet of his couch. He died among his books in 1714, after bequeathing to the public his valuable library, now known by the title of *Magliabecchiana*. (See LIBRARIES.)

MAGNA GRÆCIA, as generally used by ancient Greek authors, consisted of the Greek cities in Southern Italy that were scattered along the shores of Lucania, Bruttii, and Calabria. The cities on the E. coast were built between 735 and 685 B.C. Of these, Sybaris, Crotona, and Metapontum, were founded by the Achæans; Tarentum by the Spartans; Siris by the Ionians; and Locri Epizephyrii by the Locrians. The Greek cities on the W. coast, with the exception of Rhegium, were of a later date, and, with the exception of that town and Velia, were merely offshoots of the colonies on the E. coast. Thus, Posidonia and Laüs were colonized from Sybaris, and Hipponium and Medma from Locri. At an early period the cities of Magna Græcia, as their general title implies, outrivalled in power and prosperity their mother country. As they were, however, descended from distinct races, and were united by no common political interest, their greatness was more apparent than real—more temporary than permanent. They were often at war among themselves, and the rapid advancement of one city was frequently the result of the fall of another. Common danger was the only motive that could league them together. Accordingly, in 393 B.C. they entered into an alliance for mutual protection against the separate attacks of Dionysius of Syracuse and the Lucanians, but were defeated by the former at the River Helorus in 389 B.C. and by the latter near Laüs in 390 B.C. Many of the cities of Magna Græcia afterwards fell before the repeated attacks of the Lucanians and Bruttians. Those that survived came under the sway of the Romans after the capture of Tarentum in 272 B.C. At the beginning of the second Punic war, however, they all revolted with the exception of Rhegium. From the severe punishment that followed this revolt they never recovered. In the time of Strabo, Rhegium, Tarentum, and Neapolis alone retained traces of their former Greek civilization.

MAGNENTIUS, a Roman emperor of the west, was of barbarian extraction, and rose to the dignity of count under the Emperor Constantine. He afterwards entered the service of Constans; and in A.D. 350, while commanding the troops that defended the banks of the Rhine, he conceived the design of wresting the sceptre from that feeble and indolent prince. With the connivance of Marcellinus, Count of the Sacred Largesses, his plot was matured and carried into execution. That dignitary invited the officers of the army, then stationed near the city of Autun, to a feast in honour of the birthday of his son, and at a late hour of the banquet introduced Magnentius arrayed in the robes and insignia of royalty. The cry of "Long live Augustus" that was raised at this signal by several conspirators, was taken up unconsciously by the excited and astonished guests; and Magnentius forthwith took possession of the imperial palace at Autun. The assassination of Constans followed immediately; and within a short time Gaul, Italy, and the greater part of the western provinces had acknowledged the title of the usurper. After raising a formidable

Magna
Græcia
||

tius.

Magnes.

army, Magnentius first attempted, but without success, to negotiate an agreement with Constantine, Emperor of the East, who was already intent upon revenging the death of his brother Constans. He then marched through Italy and Noricum into Pannonia, and in A.D. 351 repulsed the troops of Constantine on the plain of Sciscia. In the same year a battle fought before the town of Mursa, on the Drave, ended in the total defeat of Magnentius. A second routing of his forces in the defiles of the Cottian Alps completed his disaster; and when on the eve of being captured by his enemies, he died by his own hand at Lugdunum, in August A.D. 353.

MAGNES, one of the earliest of the comic poets of Athens, and the contemporary of Chionides, was a native of Icaria in Attica, and flourished during the fifth century B.C. We can gather, from what Aristotle says of him, that he was the earliest comic poet of whom any victories are recorded. An anonymous writer says he gained eleven victories, while Suidas and Eudocia affirm, that out of nine plays which he exhibited, he gained only two victories. The latter statement is rendered exceedingly questionable by a passage in Aristophanes, a writer who flourished a few years after Magnes, and who, while praising his wit and versatility, charges the Athenians with fickleness and ingratitude towards the old comedian, who, from the enjoyment of an

eminent popularity had been reduced to total neglect. *Magnesia* (*Knights*, line 520, &c.) The titles of a few of the plays of Magnes constitute almost all that can be discovered respecting them. Scarcely more than half-a-dozen lines of his works are extant. A scholiast on Aristophanes signifies the *Barbitides*, a satire on a peculiar class of musicians; the *Ludoï*, an attack on the indecent dances of the Lydians; and a few others of which the authorship is doubtful.

MAGNESIA, a city of Ionia, situate on the Lethæus, an affluent of the Mæander, was commonly called *Magnesia ad Mæandrum*, in contradistinction to *Magnesia ad Sipylum*, a town in Lydia. It is said to have been founded by a colony from Magnesia in Thessaly, and rapidly rose to wealth and power. Captured and sacked by the Cimmerians about 726 B.C., it was rebuilt in the following year by the Milesians, or, according to Athenæus, by the Ephesians. Magnesia was one of the three cities that supported Themistocles during his exile, and there the memory of that great man was long afterwards preserved by a monument erected in the *agora*. In the time of Strabo the town was noted for its magnificent temple to Artemis Leucophryene, still seen in ruins. Under the Romans it was included within the kingdom of Pergamus, and from that period it seems to have gradually declined.
